Re: Research

Oct 31st - Nov 3rd 2017
Cincinnati, Ohio
www.iasdr2017.com
These proceedings contain all papers that were accepted for oral or poster presentation. All papers were submitted electronically and underwent a double-blind peer review. They are in alphabetical order by first author.
IASDR 2017 Re: Research is the seventh International Conference for IASDR and the first time it has been held in North America. We are grateful to IASDR for providing this opportunity to The College of Design, Architecture, Art, and Planning at the University of Cincinnati. Through this conference and proceedings, we are bringing the United States into the Design Research conversation taking place throughout the world. Just as the term 'design' has been going through change, growth and expansion of meaning, and interpretation in practice and education—the same can be said for design research. The traditional boundaries of design are dissolving and connections are being established with other fields at an exponential rate. The range of topics represented in these papers demonstrate the diverse perspectives of design and design research.

At the University of Cincinnati College of Design, Architecture, Art, and Planning (DAAP) we are uniquely positioned to address the current changes and challenges of design research. We seek to leverage our heritage as a city-based university and a Tier I Research Institution to support Cincinnati in redefining its role as an innovation center for the 21st century global economy. These changes and challenges also serve as the foundation for IASDR 2017 Re: Research, the rigorous dialogue provided by this platform, and the connections developed between the guest speakers from the U.S. and the international perspectives of a global conference.

IASDR 2017 Re: Research brings together over 150 papers from 25 countries. We are extremely grateful for the support and sponsorship of the University of Cincinnati, the IASDR reviewers, and all the organizations who contributed their time and economic support to this endeavor. We want to thank the University of Cincinnati Library Services for providing the format allowing these papers to remain accessible to the public in perpetuity through Scholar@UC.

Thank you for participating in Re: Research.

Abstract

When design works with industry it tries to sell two things, first, selling design as an agent of transformation, and second, selling design as a skill. Whilst historically design has been successful in the latter, it is the former that is more challenging, making it a necessity for design to work in none design contexts in order to build trust and credibility. Therefore, it is necessary to investigate the ways in which design interacts with industry, and how these interactions enable design to establish longer term relationships.

This investigation set out to answer the question, what design specific characteristics are applied to establish successful longer-term relationships between design and industry? The paper aims to illustrate the intrinsic factors that enable design to get access, and designers to get authority to play a significant role in organisations. Five well-established relationships between design and industry have been used to analyse to find correlations.

The investigation identifies three stages of collaboration between design and industry, namely, involvement, collaboration and partnerships, contrary to Cahill’s (1965) theoretical model, which claimed four stages to long lasting partnerships. Also, the case studies confirm three stages of trust and credibility as factors that help in strengthening a relationship between design and industry. Finally, several intrinsic factors that are unique to design have been identified, which are seen to have helped design in building high levels of trust and credibility.

Key words: Credibility, Trust, Design and Industry Relationship, Partnership, Collaboration

Design has two particular ways to pitch its value to industry partners, one, selling design as an agent for change; two, the ‘product-sell’ i.e. selling design through a designer for a particular skill. This paper concerns with the former, which is more challenging for design, as it requires design to work in non-design contexts. This investigation aims at identifying design specific characteristics that play a part in establishing longer term relationship between design and industry. Whilst relationship management falls under business and management research, its implications are felt by the likes of design practitioners and design consultancies that are constantly trying to establish new relationships with industry. The complexity increases when its design and the designers who are looking for collaborators, and this is largely due to underestimated value of design in business and varied standards in the design outputs and the skill of a designer.
This study investigates 5 case studies with long and well-established relationships. The findings articulate the stages of trust that are created when design works towards establishing a lasting relationship with an industrial partner. A link between trust and credibility in the relationship building process is illustrated. The paper then reveals the most important intrinsic factors that support creating trust and credibility in the first place.

**Literature Review**

**Value of Design in Business**

Junginger (2006), Burns et al. (2005) and Junginger and Sangiorgi (2009) have evidenced design’s role in organisational transformations, where various contexts (including social innovation) has given design the opportunity to act as a facilitator or an agent for change. Designing of social interactions, such as the principles with which two actors should interact and create the environment conducive for innovation to flourish is undergoing a facelift. Design has had a big role to play in shifting the centrism of relationship management from its original systems led approach into a more human centric one (Juninger, 2006, Leidka & Ogilvie, 2011 and Aftab & Young, 2016). Consequently, we have an altered understanding of the role that trust and credibility played in building these social interactions.

**The Value Of Trust In Building Relationships**

Social interactions between two actors working towards innovation might begin with the initial meetings, where both parties might question: why do you want to talk more with me? Why should I want to talk more with you? These questions could help identify a common purpose for the actors, and begin the next stage of the relationship, before progressing to a more collaborative one. One or both parties might give signals to have conversations about what they should give and take for the next stage (Gee, 2015). This process, where both parties commit time, and work together in a particular project, might promote trust that will facilitate the next stages of the relationship.

Whilst building trust is closely linked in having and maintaining good relationships, both personal and professional. Hacker et al. (1999), Kadefors (2004) and Hooghe et al. (2012) agree that trust has manifolds of applications for design consultancies. Stone (2010) states that exceeding industry partner’s expectation results in higher level of trust, and consequently leads to longer relationships. Also, Best (2006) states that trust could build confidence amongst the consultancies and their industry partners. However, lack of trust might cause more damage, where the collaborators feel cynicism, doubt and anxiety.

**Dimensions Of Trust**

Lewicki and Bunker (1995) identify three different stages of trust; stage one as calculus-based trust (CBT); stage two as knowledge-based trust (KBT); and stage three as identification-based trust (IBT). CBT begins with a low investment from both sides. The relationship might be defined by a contract, which clearly articulates costs and benefits; a transactional relationship. This stage is monitored through constant reporting between the parties, and there is a level of tolerance between parties. KBT begins as soon as both the parties have gained a good understanding of each other through working together over a
period of time. In this stage both parties can predict each other’s behaviour, however a conflict at this stage might reduce the willingness to trust. The third and the hardest stage to reach is the IBT where both parties not just understand each other, but also endorse each other, and could act on behalf of each other in an interpersonal transaction. During this stage the parties are seen to have a high level of empathy for each other. Whilst these stages might feel as though they follow a linear progression, in reality they are highly dynamic, as the levels of trust in each stage fluctuates with the increasing length of a relationship. Additionally, there are multiple factors that influence each of the stages and the progression of a relationship into the next stage.

Studies conducted by Saparito, P. & Sapienza, H. (2002) and McAllister et al. (2006) support Lewicki and Bunker’s theory. They suggest that the longevity of the relationship might be one of the factors that are of utmost influence. However, in terms of industry relationship, previous studies suggest that trust is a conceptual model and it is built through the development of capability, commitment and consistency between the parties involved.

Factors Influencing Trust

Pavlidis (2011) identifies extrinsic and intrinsic trust factors that have an impact on both engaged-parties in the context of a consultant/industry partner relationship. The extrinsic factors play an important role when the ‘company’ gathers all the knowledge about the ‘designer’ without any direct experience (e.g. knowledge of the reputation/past credibility) and vice versa. Meanwhile, the intrinsic factors would cover all of information gathered during the experience of relationship building when both parties interact. Furthermore, several studies consider the intrinsic trust factors that might influence trust building. Those factors are more like trust antecedents and help us calculate how much of trust a party would give to another party in a particular relationship. Mayer et al. (1995) and research conducted by Hacker et al. (1999), Kadefors (2004) proposes those factors to be; ability, benevolence and integrity. They confirm that the interrelationship amongst those three factors impacts the achievable levels of trust. The higher each factor is indicated, the higher level of trust the industry partner is seen to give to a designer (Mayer et al., 1995).

Pavlidis (2011) concludes that during the initial stages of the relationship; the extrinsic factors have a stronger impact on the decision making by both the parties. On the other hand, in later stages, Roxburgh (2003) states that the intrinsic factors are more influential. Whilst most see trust as a critical element in building a successful industry partner relationship, there are many other factors that need to be briefly mentioned here. These other factors contribute towards the relationship process, such as teamwork, resources, time and the project itself. For Sheddy (1997, cited in Du Plessis, 2005) in terms of marketing, trust also has an important role to play in managing the quality of interactions and the industry partner’s commitment to the relationship. In this context, the relationship would be closely related to project management, where the designer should set a strategy to deliver qualified works in order to increase the level of trust. Best (2010) suggest that delivering a successful design is aligned with punctuality, budget and profit; hinting at a combination of the ‘creative competence’ and ‘managerial competence’ for project success.

Lewicki and Bunker (1995) believe that a lasting industry relationship might also depend
on how a relationship is managed i.e. where each collaborator is influencing one another and delivering benefits for each other. According to Boyle (2003), the relationship between a designer and its industry partner also requires effective and frequent communication and good design process that is based on clear roles and responsibilities (Best, 2006). Also, Kadefors (2004) work concluded that a higher level of trust could increase the standard of the design project. However, for Hacker et al. (1999), every interaction between the designer and industry partner would build trust over time. In this case, both parties should be willing to involve in a particular project, by giving their time, resources and effort. Nevertheless, a study by Mayer et al. (1995) shows that trust might not be needed for collaboration. So, if trust is not needed for collaboration then what is the next important factor that makes two parties collaborate?

Du Plessis (2005) believes that credibility could be the answer. Credibility could be added to the establishment of long-term relationship and the existence of trust. Also, whilst lack of trust would damage a relationship, lack of credibility might have a negative impact on the trust building process itself. However the case, it could be a combination of both the creative and management competencies that influences trust. In this context, trust, credibility and long-term relationship might be universals and should be applied to all collaborations. Regarding the trust-building process, several authors point out that credibility might overlap trust. So, what is the role of credibility in terms of trust and long-term relationship building process?

Value of Credibility In Building Relationships

Trust and credibility are competencies and characteristics (Covey & Merrill, 2006). Credibility simply means the quality of being trusted and believed in (Du Plessis, 2005). Essentially, credibility should be established by a combination of several elements and building of trust should follow good credibility. The presence of credibility is essential and it is what makes up the ‘elevator pitch’ on the websites of most design consultancies. Reflecting on design’s perspective on credibility, Du Plessis (2005) considers that credibility covers three dimensions as follows;

- expertise (competency, innovativeness and being market leader),
- trustworthiness (being dependable and meeting customers’ needs), and
- likeability (being fun, interesting).

Ferguson (1999, cited in Du Plessis, 2005) also agrees to trustworthiness and expertise as being the two essential elements for building credibility. Additionally, Covey & Merrill (2006) explores that there are four main elements that could build credibility; integrity, intent, capability and results. McCorey (2005) added four stages for establishing credibility; rapport, trust, influence and persuasion. Firstly, rapport that could help a designer set the base of the relationship. Secondly, trust should exist that might accelerate the time to achieve the result faster. Thirdly, influence should cover the ability of leading the hearts and minds of people that has been built from the previous stages of rapport and trust. Lastly, persuading the industry partner to take action based on the designer’s recommendations. These four stages should measure the effectiveness of the relationship by capturing the benefits and tracking down the number of projects (McCorey, 2005).
Barr (2015) states that building trust and credibility are activities of day-to-day processes and also an essential tool to maintain the industry partner relationship. Trust might be a primary factor in how people collaborate in a particular work and build an industry partner relationship (cited in Saparito, 2002). Additionally, Du Plessis (2005) believes that credibility also has a role in driving the relationships.

On the other hand, a study by Simons (2002, cited in Du Plessis, 2005) argues that credibility may not be part of trust at all. He suggests credibility to be considered as a behavioural integrity. However, Devlin & Devlin (2010) illustrate the need for establishing credibility in order to increase the level of trust. His framework suggests that trust and credibility might be created by three essential factors; knowledge and expertise, openness and honesty, concern and care (Peters, Covello and McCallum, 1997). This study revealed that the concept of trust and credibility depends on the context of application. For instance, there would be different levels of trust and credibility amongst industry, government, citizen and as well as society.

Whilst literature illustrates that trust and credibility are important and have a role in building successful industry partner relationship, the interrelationship between trust and credibility is still very subjective. There are studies that both agree and disagree with the similarity between these two concepts. However, understanding the concepts and the interrelationship between them might help in relating how they influence the relationship between a design and its industry partners.

Trust, Credibility and Lasting Relationship

From design field’s point of view, industry relationships would be closely related to project management and communication, to deliver quality work in order to increase the level of trust. However, an important question here is, how you build trust when working with a profession (design) that embraces failure as a necessary aspect of securing success?

Increasing level of trust and credibility should influence the development of a relationship. According to a study by Cahill (1996), relationships are established in four distinct stages (Figure 1), partnership being the one that a long-term bond should aim towards. She suggests that a relationship would commence when people who participate get involved in a particular project or piece of work. She believes that when people begin to collaborate, it results in greater involvement towards the next stage of the relationship, which is a true partnership (shown in figure 1).

![Figure 1. A Continuum of Involvement Model by Cahill (1996)](image)

The paragraphs below have tried to ascertain if Cahill’s model applied to any of the partnerships between design/designer and the industry.

Research Context and Process
Post reflection of projects undertaken between a UK based University and a global FMCG brand based in The Netherlands since 2006 until 2016 was conducted. Projects were grouped together and placed on a timeline based on the level of partnership, anticipated value and impact, and then mapped onto Cahill’s (1965) theory. A framework was created which illustrated the trajectory of the evolving partnership between the two parties. The framework was then mapped onto Lewicki and Bunker’s (2010) four levels of trust, and McCorey’s (2005) four stages for establishing credibility to illustrate the role of trust and credibility in building longer-term relationship with design. This revealed interesting but subtle differences in the way design projects and designers form new and strong industry partnerships.

Additionally, four design consultancies that have successful long-term contracts with large industry partners were engaged in unstructured interviews to explore the social factors that affect the process of building such successful industry partner relationships. The reasoning behind engaging with consultancies was due to their ability to gain access to industry projects on a longer term, and the authors are convinced that this was an opportunity to learn from their achievements. A summary of each case study is given in Appendix 1 (Table 1).

Findings and Conclusions

1. Framework for Long Term Partnerships
   Cahill’s (1996) theory was taken as a baseline and then compared with the 10-year relationship in case study 5, to create a framework. The project type, outcomes and impact of the projects conducted during the 10 years relationship was plotted on to Cahill’s framework (Figure 2).

   ![Figure 2. The Shifting up of Trust Level Model](image)

   A. A Continuum on Involvement Model by Cahill (1996)
   B. Project level of engagements between Design School and Company-A by Bailey et al. (2015)
   C. The Shifting up level of Trust by Lewick and Bunker (1996)

   The findings from this stage indicated that there was a correlation between the nature of the projects and the stages of the relationship, and design led relationship building had three stages of working together. For example, the initial stage (called involvement stage) had short (around 3 weeks) live projects involving a student cohort, with clear benefits to the students learning, and explicit outcome in form of ideas to the industry partner. These projects elaborated the skill of a designer and did not concern with the impact and value of
design within the business. In fact, these short students led projects built enough trust between the two parties that both were able to progress in creating projects more suitable for the next stage.

Stage two combined collaboration and participation into projects of a kind, which were discretely based on co-creative activities between the students, academic staff, innovators in residence (a quasi-consultancy offering a bridge between academics’ research and the partner’s project requirements) and the industrial partners. Projects conducted in this stage were longer, and involved more stakeholders. The academic staff involved in increasing the understanding of the value of design within the partner organisation. These projects elaborated on the overall value of design on business skills instead of just developing a design skill. However, the projects had an end time and whilst co-creation did seem to increase the capacity of design within the partner organisation, the overall impact of running such learning and teaching based co-creative projects was still unknown.

Further, stage three is seen the hardest to achieve even after 10 years of collaboration. However, due to the increase in the capacity of design within the partner organisation, a partnership project was established between the two institutions, which is ongoing. This partnership was formalised to develop an understanding of the breadth of the role that design could play within the organisation and exploit its capabilities for the mutual benefit of the organisation, academia and the students.

Illustrating the Four Levels of Trust on the Partnership Framework

Lewicki and Bunker’s (2010) four levels of trust were then superimposed on to the framework. This confirmed that the project outcome and its impact on the collaborating company played a role in the progress of the relationship into the subsequent stages (figure 2). For example, the educational institute had enough credibility to kick-start projects from a calculus-based trust. Hence, the initial student-driven projects. As a result, this led to a rise in trust between the institute and industry partner, consequently allowing design to get better access of the internal decision making process of the organisation through co-creative projects.

These co-creative projects were seen to build capacity for design within the organisation, hence a culture of mutual understanding flourished. The most obvious insight gained from this stage was an increase in the credibility of design as a concept and its impact on innovation.

Illustrating the Construct of Trust and Credibility in Building Partnerships

The combination of Lewicki and Bunker’s (1996) three stages of trust and McCorey’s (2005) four stages for establishing credibility illustrated the importance of trust and credibility for a long lasting relationship. However, the theoretical construct of trust and credibility provided by Du Plessis (2005) suggested that credibility might be independent of trust. Hence, a theoretical analysis was conducted to ascertain if this was applicable in the case for design. The finding illuminated that trust in design and the credibility of a designer have to grow incrementally and simultaneously in order for a relationship to progress from the first level of mere involvement of the industry partner into the stage of a partnership (Figure 3). Whilst progress towards partnership required the designers to show
their abilities (credibility) in handling advanced projects, the partnering company also needed to advance in its belief (trust) for design as an agent for change. In this case study the former was easily achieved but the latter was more difficult.

Confirming the use of trust, influence and persuasion in later stages of relationship building

Mapping McCorey’s (2005) four stages of credibility on to the framework (Figure 4) led to conflicting results. It illustrated that whilst live projects did help in building a good rapport and vice versa, it was the confluence of all the other stages of credibility (i.e. trust, influence and persuasion) that enabled design to have a bigger role in the organisations internal decision-making process. In fact, the initial project meetings evidenced strong persuasion from design to convince the industry about new opportunities for collaboration. Therefore this confirmed that the four stages of credibility were, in effect, four important elements that a designer must apply, in order to pursue a lasting relationship.

5. Trust Model Creation

Finally, the analysis of the first 4 case studies led to the construction of a trust model (Figure 5). The model articulated several intrinsic factors that were deemed important to establish trust and credibility.

Elements like ability/capability, benevolence and integrity were pre added as they were supposedly considered key to building credibility by the literature. Later, the 4
consultancies also confirmed their significance and added that these elements represented the qualities that were needed in the individuals work within the consultancy; used specifically when a designer is trying to sell a particular skill.

Also, more elements, such as, adaptive approach, passion, multidisciplinary teams perspective, face-to-face meeting, empathy, flexibility, and less negotiation were added to the model. These elements represented the principles which design used in its interaction with their client whilst selling design as a concept and not just a skill. The trust model also confirmed that ‘time’ is not a factor in building long relationship.

![Figure 5: The trust model creation and validation](image)

Finally, the investigation and validation of the trust model led to the identification of four key intrinsic factors that were important in establishing trust and credibility, and were seen particular (but not exclusive) to all design led partnerships. These are,

1. clear **passion** for design by the industry partner

   Whilst Stone (2010) suggests that being passionate about ones design could boost credibility, it is the passion for design by the industry partner, which was seen as a clear factor in creating an initial appetite for design’s inclusion in organisational practice. This allows industry to involve design and a solution provider to pitch design’s abilities.

2. **design leadership**
Projects through industry partnership are one of the ways in which design’s capability as a leader for transformational change are demonstrated. Consequently, this has led to a better understanding of what design could achieve if given the opportunity to participate in non-design contexts, such as organisational culture change, transformation, innovation, thereby adding to design’s credibility.

3. *empathic* interactions

Often a design project starts with a friendly meeting, but this is never enough to establish and maintain a lasting relationship. Frequent face-to-face meetings and honest and transparent communication, where the designer could claim the industrial partner to be wrong, are seen as essential for building trust. Add to this the element of empathy (Michlewski, 2008) and a new form of relationship building principle emerges. Currently, many have evidenced the use of empathy in creating social interactions, and the authors see its application within the relationship building process as well.

Although the trust model (figure 2) identified negotiation as a frustrating aspect for industry partners, it is a necessary step for the designer when managing expectations. The case studies evidenced that negotiations are essential to balance the time, budget and quality constraints for projects. Here, the role of empathy as suggested by case study 3 is shown to be of great value in leading short but effective negotiations.

4. *agile* process

Time management is crucial in all design related projects, but it gets challenged when design is made to work under strict budget constraints. Hence, a process that allows the solution providers to adapt is a must.

The development of long lasting industry partner relationship with equal mutual benefit is largely influenced by trust and credibility. However, trust and credibility is built by other intrinsic factors, which are not easy to apply within a project space. Nevertheless, once the combination of these factors is established a greater and longer relationship can be nurtured. In terms of building a good industry partner relationship, trust and credibility might work collaboratively, but both should also work independently.

The paper confirmed the need to nurture trust and credibility together, throughout the four stages leading up to partnership, in order to ensure progression into a longer-term relationship. Also, it stressed importance of using a number of intrinsic factors that were found important for any design led relationship building endeavour; passion for design by the client, showcasing design leadership, empathic interactions, and agile processes.

**Implications and Future Research**

This research has greater implications for early career/start-up designers. Whilst the sample size for this research involved designers at various stages of their career, the findings might be of interest to design practitioners who are hoping to start their own venture. The implementations of this study should motivate them to build the trust and credibility not only to achieve their goal, but also to establish their industry partner relationship.
The exploratory nature of this investigation could be considered as purely subjective. However, the mere scope of the study challenges us to explore the research from different perspectives. Moreover, there is limited literature discussing the importance of credibility and trust in design field, and further research needs to be done to investigate the role of trust and credibility from the perspective of industry partners. Industry partners might consider outcome, impact and profit as more beneficial, which will give a completely different context for what has been discovered. An important question to ask would be, what are the downsides of long-term relationships?

Additionally, another interesting aspect to be explored should be the role of a leader, in building trust and credibility with the industry partners. A leader should be able to inspire trust. At this end, a designer that has a trustworthy leader could accelerate growth, improve collaboration, and strengthen partnerships.

From the previous findings, design project management and communication were emphasised as the important aspects in achieving design success; whereas this research explored and related those aspects to the concept of trust and credibility. The elements of trust should build the quality of being trusted, which leads to the establishment of credibility. Like trust, credibility also has a value in the relationship.

Lastly, through trust and credibility design might be able to nurture and maintain lasting relationships with industry partners and thereby sustain livelihoods. Nevertheless, if the real purpose of the partnership is for design to position itself as an important resource for industry, and be given easy access to work in non-design contexts, this will only happen when design has demonstrated credibility by working in such contexts and gained the trust of industry. This is such a paradox, and the only way out of this is through the application of the intrinsic factors in all industry partnership meetings i.e. constant persuasion, communication, and (design) leadership.

<td>Case 1</td>
<td>Consultancy got projects off the ground in 2013. Two individuals, one with business and one with design background.</td>
<td>Creativity in selection of the project is what they believe one of the primary criteria for a successful collaboration.</td>
<td>They encountered challenges during their start-up phase. These challenges were around forming long-term relationships with clients. It was good communication and transparency with their clients that helped them. Whilst they agree that understanding the client’s need at the start of the project is crucial, it was the management of the client’s trust, passion and skills that were decisive if the relationship would last longer.</td>
<td>They have a clear process that their client’s engage in, 1) Research, 2) Selection, 3) Brief, 4) Trust, 5) Freedom, 6) Communication. They work with several constraints like time and budget. However, managing client's expectation is one of the biggest constraints they prioritise from the start of a project.</td>
</tr>
<tr>
<td>Case 2</td>
<td>Consultancy began in 2011. Small team with two designers. The office is used as a co-creative space where they meet clients. The team works away from home on the projects.</td>
<td>They engage with the clients in an office space only. This they feel is one of the key initiatives to gain the clients trust early on in the process. They keep the client involved in constant feedback loop throughout the project process.</td>
<td>They have managed to build a long lasting relationship through consistent use of empathy. They also encourage employing personal time and space to build a relationship with their client on a deeper level. They believe that design can become an integral part of their clients business, especially if the design consultancies are not too selective of the kind of projects they conduct.</td>
<td>They do not have a clear process, as they believe each project has a unique approach. However, they confirm that they begin with research, and then follow it up with design work. The projects always have rigorous quality control before client feedback sessions. They worked with budget restraint only, and focused on helping the client in their business, whilst collaborating in projects.</td>
</tr>
<tr>
<td>Case 3</td>
<td>Since 2009. Small team with 3 design consultants.</td>
<td>Through long-term collaboration, they have been able to develop an assessment tool that categorises clients into three sets. Where the first two sets are the ones that have the potential to become long-term relationship and the third set recognises clients who will never go beyond a project-based relationship. They build capacity to work with the clients based on the assessment. They believe that the reputation of their creative lead enabled them to</td>
<td>They build capacity and capability with each client based on the assessment tool. If the client is in the first 2 sets, then the consultancy puts in more resources and time in the initial interactions. They confirm that the initial interactions are the most challenging, as both, the client and the consultant do not know much about each other. And it’s the little extra time that they spend together that builds the relationship stronger for later. Additionally, they</td>
<td>They are keen on working with clients who have small ambitions. They take on short projects with small goals that have better chance of success. They do not see their process to be very different from other consultancies, but they believe that through rigorous internal evaluation of projects, they have been able to improve their process for subsequent projects. Hence, building credibility and trust with their client. They put regular and</td>

**Author Biography**

Meidirasari Putri
Dira undertook a visual and communication design BA degree in Indonesia. To gain further knowledge in management and business start-up, she chose to study the MA Design Management at Northumbria University? Newcastle, UK. Her concern is that good design reveals itself when designers see not only the aesthetic but also the real needs of human beings. She focuses on creating tangible experiences.
Mersha Aftab
Currently senior lecturer in Innovation at the Department of Design, Mersha Aftab started working with Northumbria University, in June 2012. She has a Masters in Design Management and a doctorate in Design from Northumbria University. Mersha joined Philips Design as an intern in 2010 under a collaborative scholarship scheme between Philips and Northumbria University. In 2013 she was awarded her doctorate in the topic ‘design as a functional leader: a case study to investigate the role of design as a potential leading discipline in multinationals’. Mersha’s work has led her to collaborate with Nokia, Daimler, Sony Ericsson, Lego, Google and Samsung. Mersha’s interest lies in exploring the role of design in triggering a change in the culture of organisations.

Mark Bailey
He leads the Faculty of Arts, Design and Social Sciences’ design-led innovation activities at Innovate and the focus of his work is design-led Responsible Innovation Practice. He also leads the University’s partnership with Unilever along with a number of other business partnerships and is Northumbria’s Principle Investigator for the £3m, AHRC funded collaborative research programme Creative FUSE North East through which the five North East universities are seeking to drive economic growth in the Creative, Digital and IT sector. He teaches BA(Hons) Design for Industry and MA/MSc Multidisciplinary Innovation. Mark has worked in Higher Education for the past 20 years having previously spent ten years leading design and development projects in the Aerospace industry where he worked on advanced passenger and business jet concepts as well as designing bespoke private jet interiors. He has also led a small design consultancy business. A highlight of his early consultancy career was designing the best-selling ‘Little Professor’ for Texas Instruments!

Nicholas Spencer
Nicholas is Programme Leader for the MA/MSc Multidisciplinary Innovation programme. In this role Nicholas helps to develop international educational partnerships that develop new forms of innovation for external commercial and third sector organizations through novel academic, student and community co-creation. Nicholas' first degree is in industrial design and his Doctorate focused on expert designers' experience of practice. Teaching design research into the Design Department's Postgraduate provision and supervising Doctoral Research programmes supports and is supported by the personal research focus of developing new understandings of networked design intelligence.
A Content Analysis of Wired Magazine and Self-Tracking Devices

Serefraz Akyaman, Sakarya University, Turkey, serefraz@sakarya.edu.tr

Abstract

Living in a modern society is becoming more complex, so in order to keep up with, a person should accomplish various kinds of task at once. Daily life requirements, obligations and the capacity of human memory lead us to collect and control our behaviors, bodies and lives through self-tracking devices. Aim of this paper analysis of emerging digitalized self-tracking trend through content analysis of Wired Magazine. Wired Magazine, both in printed and online, monthly, publish technology related articles how emerging technologies affect culture, the economy and politics. It reaches more than 30 million people each month through wired.com, digital edition. Since the term 'quantified self' emerged for the first time in Wired Magazine, for this reason Wired Magazine is one of the most important sources to be used for content analysis. This present study carries out a content analysis of all the issues until December 2016 through 'self-tracking' and two other related terms: 'quantified self' and 'lifelogging'. The usage period and popularity of these terms and, the relation network with the main topics and the sub-topics are examined. As a result, it is possible to define wired magazine as a medium in which industry-academia and users come together and, feed each other reciprocally. Wired Magazine have contributed significantly and continues to contribute to the development of the digitalized self-tracking trend in terms of its content.

Keywords: self-tracking quantified self, lifelogging, content analysis, trend analysis

Introduction

People are bombarded about daily responsibilities and tasks. It takes effort to meet daily requirements about work and private life. Compared to the past daily life, before computerization, today's network of relationships established throughout the day is quite difficult for a person to follow. Therefore, individuals need to get support from the artificial objects at a certain level in addition to his or her memory for everything need to be followed within tasks or job. Self-tracking devices arise from the intersection of these requirements, obligations and the capacity of human memory. Lupton (2016) notes that in recent years detailed quantifiable data have gained value over the value of one's other forms of information about life, health and well-being. The process of digitization has begun to accumulate the individual's self-consciousness, to push for a more holistic sense of self. While the support of the technology may simply be reminiscent of what to do (remembering future events), it can also store and organize information about a person, such as physical activity (Figure 1e: Fitbit charge 2; Figure 2h: Wellcore Wellness activity tracker & fall detection device for seniors), amount of water consumption (Figure 2f: The Pryme smart cup), seizures (Figure 2c: The Embrace smartwatch for spotting epileptic seizure), sleep quality (Figure 2e: SleepImage sleep tracker) etc. It is not new activity that an individual record his or her personal data, it has been already done in history through pen and paper, but with the digitalization of the world, trend of digitalized self-tracking activity emerged. For identifying this emerging trend, various industries had been searched for clues to support it. As a result of these investigations, products designed with similar approaches were seen in the health, fashion and furniture industries.
In the furniture industry, automobile company, Ford designed microphones and sensors embedded a smart crib for babies (Figure 1a). The crib is designed for helping parents to get the baby back to sleep by rocking the crib via monitoring baby’s sleeping patterns. In the health industry, UpRight which is a funded in Kickstarter designed as posture corrector (Figure 1c). It gives feedbacks via vibrations to improve one’s posture and tracks daily activities. Another example in this industry is Elf Emmit stress relief headband which aims “improve focus, sleep, meditation and learning processes, while combating stress by combining ancient traditions and modern technology” (Figure 1d). It has five different programs that tracks specific data about user and use it for improvement. Last example in this field is a smart wristband Fitbit charge 2, which is basically an activity tracker, but also can track sleep and work as a reminder for move (Figure 1e). Another example of fitness tracker in fashion industry is Hexoskin biometric tops (Figure 1b), which is a piece of cloth that can track various physical data as heart rate, breathing rate, steps, sleep positions, etc.

This emerging trend started to arise in the health industry. A quiversful of wearable sensors is becoming widely available and these let us measure data about our health, as well as receive immediate feedback about how we are performing. The products developed with wearable sensors are basically starting to learn us and intelligently collect data about us or interrupt our daily life for optimal health and productivity outcomes. Since the data that obtained from the users are also differ from each other, tracking devices will ultimately be customized for each person. The National Institute of Mental Health (NIMH) have listed current trends in app development as:

- Self-management apps
- Apps for improving thinking skills
- Skill-training apps
- Illness management, supported care
- Passive symptom tracking
- Data collection

Several terms in addition to ‘Self-tracking’ practice which defined as monitoring, measuring and recording aspects of one’s body, behavior and life; such terms are lifelogging, personal informatics, personal analytics and the quantified self (Lupton, 2016, p.8). Personal informatics and personal analytics terms often used in academic literature in the area of human-computer interaction (Lupton, 2016, p.9). The term lifelogging, which is regarded as the most rooted one, emerged in the early days of personal computing (Sellen and Whittaker, 2010). Lifelogging defined by Selke (2016) as a heuristic collective term, refers to diverse types of self-tracking
that range from health monitoring and the detection of one’s location and presence to the measurement of productivity at work (p.1). Krynsky (2010) also defines the lifelogging term as “the process of tracking personal data generated by our own behavioral activities”.

The terminology related to this emerging situation only recently started to become clear. Wolf and Kelly realized that the people around them were collecting data about themselves, seeing this personal data collecting culture as a new trend and introducing the term ‘quantified self’ to describe this detailed digitalized self-tracking phenomenon. Later, in his article published in *The New York Times* in 2010, Wolf described the term self-tracking as “self knowledge through numbers”. The quantified self (QS) defined by Swan (2013) as ‘any individual engaged in the self-tracking of any kind of biological, physical, behavioral, or environmental information.’ For indicating the difference, the term of lifelogging can be defined as a form of transformation that allows to collect all kinds of personal data digitally or non-digitally for the purpose of later reflections while the QS can be defined as collection of one’s personal data and the search for ways to achieve some predetermined physical or non-physical changes by making associations over accumulated data.

**Literature Review**

One of the main factors that enables QS devices to emerge is technological developments besides human needs and demands. The term referred to in the literature as ‘the internet of things’ and defined as “the general idea of things, especially everyday objects, that are readable, recognizable, locatable, addressable, and controllable via the Internet - whether via RFID, wireless LAN, wide-area network, or other means” by the U.S. National Intelligence Council (2008), is important in this occasion. This term has been instrumental in the emergence of QS devices, which are capable of constant activation and real-time data exchange and evaluation. The emergence of digital technologies that can help in collection, calculation and demonstration of personal data is crucial in the development self-tracking phenomenon (Lupton, 2014; Lupton 2016). Those digital tools which embedded sensors and microprocessors are used to collect relevant data mostly quantitatively to name some variables such as body functions, emotional states, sexual and social encounters, work efficiency, physical activities and geographical locations through movement, sound waves, temperatures and other data. In some cases personal data can be collected and displayed qualitatively using words, pictures, and objects (Lupton, 2016). Quantitative or qualitative data about a person is actually a part of one’s self-fulfillment adventure. Supporting health-related behavior change, collecting data for future conditions about body and mind is essential for allowing the individual to control and to satisfy themselves. Possibility of discomfort in daily actions, or for just transmitting one’s everyday life to third person’s eye, people have been constantly storing a lot of information whether physical or non-physical about themselves. Most of the time digital self-tracked data are stored in the cloud-based computing system that only developers can access and use it for their purposes (Lupton, 2016).

For centuries, people have been using non-digital technologies to monitor and measure the physical or non-physical characteristics of themselves. Mobile digital devices connected to the Internet have facilitated real-time, more detailed measurement and monitoring of body and daily life, also simplify the analysis, presentation and sharing of these data (Lupton, 2016). These data that are tracked and measured can serve in different areas. According to Selke, the term of lifelogging can basically be examined in 4 category: monitoring health, human tracking (Gps or radio cells), human digital memory and surveillance/sousveillance (2016). It is basically
aimed at storing the actions we have taken at that moment and accumulating them for use when the time comes. The French sociologist Gabriel Tarde commented about the further development of society and social statistics in 1890;

“a time may come when upon the accomplishment of every social event a figure will at once issue forth automatically, so to speak, to take its place on the statistical registers that will be continuously communicated to the public and spread abroad pictorially [...] Then, at every step, at every glance cast upon poster or newspaper, we shall be assailed, as it were, with statistical facts, with precise and condensed knowledge of all the peculiarities of actual social conditions” (Tarde, 1903 s.133; Gertenbach, Mönkeberg, 2016).

Tarde's utopian view has evolved over time and with development of technology, it has begun to gain a more realistic and possible dimension. In the 1980s, the attention of social and cultural theorists began to draw the relationship between the human body and computer technology. The concept of cyborg has been a source of inspiration for the cultural theorists who have written about the effects of computerized technologies on human configuration and subjectiveness (Lupton, 2012). One of the earliest examples of lifelogging is Steve Mann's work, the EyeTap project in the early 1980s. Since 1994, he has started to broadcast his life on the website 7 days 24 hours, and over time, this process was opened up to instant viewers and moved to a level where they can be involved. Also in the mid-80s Mark Schulze, a mountain biker, created the first helmet cam by rigging a video camera to a portable video recorder (Winchester, 2015). In 2004, the first GoPro was launched to take adventurous in time photographs. Another study in the early 2000s that attracted attention was Microsoft's MyLifeBits project, where researcher Gordon Bell digitally captured a lifetime's photos, messages and work, while colleagues designed software to navigate it (Stuart, 2014).

Living in a modern society is becoming more and more complex, and in order to keep up individuals are required to accomplish various kinds of task at once. Aforementioned multitasking lifestyle drives us to keep up everything happening around us at that moment or in the near future. Sometimes this exhausting journey leads us to get affected physically and mentally. Being aware of this situation basically provokes us to be better. By collecting digital data, people aim to reach healthier biological body and overall to reach a better life level. Ultimately the core of the ideologies of the lifelogging movement is the idea of “creating a better human” (Gertenbach, Mönkeberg, 2016). At present mobile phones which can collect and keep large amount of data, it generally processes data about how we use that device or our action patterns in a specific area like walking or running through GPS or radio cells. Since the advent of smartphones and tablets, numerous commercial applications have been created, many of which are directed at consumers who wish to track or monitor their exercise, dietary or sleeping habits, pulse, or even more private personal data such as fertility or menstruation cycles. It is possible to discuss the usability of applications that compile data about more than one area and require the individual to take and engrave measurements which obtained manually. People have been storing data about themselves manually for centuries (Lupton, 2013). The relationship between an increase in the efficiency of an activity that has been going on for such a long time and the production of devices capable of automatically processing data in a specific area and without being aware of the individual is worth investigating. This relation in software has led the emergence of new and specialized products for each specified activity, products that aim to bring us to a better level both physically, mentally and emotionally. For example, activity tracker Jawbone has an “idle alert” feature to preventing users from sitting too long by
vibrating. Another one, HAPIfork which designed for helping users have mindful eating habits, also
vibrates when fork using frequencies shorter than 10 seconds. This utensil aims for eating speed control by the right amount of chewing (Schüll, 2016).

Some organizations, including private institutions, and even the governmental state encourage use of healthcare applications more commonly through health promotion campaigns. This effort mainly for translating someone's potential use into meaningful data through recorded information about their activities or eating habits, etc. Therefore, those organizations constantly create reminders for us to be in health-promoting behaviors (Lupton, 2012).

According to Department of Media and Information in Apple app store and Google play store, currently there are more than 97,000 health-related apps available in the health and fitness category and every month more than 1000 items are added, with about 1000 more being created every month. It is anticipated that every year this amount will add up to 25% more new health related applications. It is anticipated that they will be added by 25% every year (Peng et al., 2016). It should be noted that besides the applications used only on mobile phones, many customized products are designed today. These products include smartwatches (Figure 2b), wristband sensors (Figure 2c), wearable sensor patches (Figure 2a,d), artificial reality-augmented glasses, brain computer interfaces, wearable body metric textiles (Swan, 2013).

![Figure 2. Self-tracking gadget examples from Wired Magazine](image)

a: Fuseproject Kernel of Life  b: Moodnotes  c: The Embrace  d: Lumo Lift  e: SleepImage  
f: The Pryme Smart Cup  g: Bellabeat  h: Wellcore Wellness  i: Lapka

Among these products wearable technologies are also quite varied. Products that specialize in a number of areas are available and usable via a smartphone or computer program. These devices, which present the user with the resulting data in the form of figures, texts, diagrams, notifications and alerts, are still entirely focused on the desire to improve one’s self. The wearable products intelligently collect data about users or interrupt daily life for optimal health and productivity outcomes. For example a device called Kernel is being developed by Fuseproject in response to a brief from Microsoft owner Bill Gates’ charity the Gates Foundation and Wired Magazine (Kernel Diagnostic Amulet, n.d.). Kernel is cloud-based test and treatment system for illness, especially malaria (Figure 2a). Other example is Moodnotes which designed as a personal trainer for user’s mental health (Figure 2b). Moodnotes works as a mental diary, tracks user’s mood and determine what influences it and helps users to build up healthier thinking habits. Since the data obtained from the users are also different from each other, those devices are ultimately customized for each person. The National Institute of Mental Health (NIMH) have listed current trends in app development as: self-management apps, apps...
for improving thinking skills, skill-training apps, illness management, supported care, passive symptom tracking and data collection. Apps and gadgets use the device’s built-in sensors to collect information on a user’s typical behavior pattern, promise to improve memory or thinking skills. These behavior patterns have begun to vary in the following forms: physical health (how energized/healthy you are), emotional health (how you are doing in general, whether you are feeling positive vibes), and mental health (how efficiently you could focus today, how creative you are). There are currently 505 registered tools listed on the Wolf’s website, quantifiedself.com that serve this purpose. (Quantified self-guide 2017). Devices that designed for this issue mainly deal with some output obtained by measuring (conditions, symptoms, genome, biomarkers, behavior, environment) the actions (research, treat, intervene, experiment, track, measure) of a person. Swan (2009) lists these outputs as: self-expression, enhancement, prevention, normalization, improvement and cure.

**Research method: Content Analysis**

This paper aims to investigate the progress of digitalized self-tracking trend since its inception through the alteration of self-tracking applications and gadgets subject to Wired magazine. To meet that goal a content analysis of Wired Magazine from the first January 1993 volume to December 2016 volume was conducted. Wired Magazine is an American magazine establishment published both in print and online monthly. It publishes technology related articles and on how emerging technologies affect culture, the economy and politics (Wired). This magazine is chosen as medium of data collection, because it reaches more than 30 million people each month through wired.com, digital edition. In the literature review, frequently used terms to define the field were accepted as key words (Self-tracking, quantified self and lifelogging) and used to analyze the articles published in the magazine. Those selected keywords are that formerly listed as: self-tracking, quantified self and lifelogging.

**Results & Discussion**

There are 109 results for “quantified self”, 23 results about “self-tracking, and 13 results for “lifelogging” terms in online database of wired.com (see Table.1).

When the articles published in the first years of the magazine are examined, it can be said that these terms which are relatively new have emerged from the concept of "tracking/tracker" and “monitoring”. There are 1070 results in health monitoring, 1368 results for tracker, and 2007 results for self-track keywords.

It can be seen that the articles about the key terms have been started to be written in 2009 as a result of the obtained data. It is seen that the technological developments have been examined
since this date, and the products and applications serving this purpose have started to launch. In the late 2000s, and Apple and Nike's collaboration on the Nike+iPod fitness tracking device gave consumers a way to use their existing technology to keep fit (Winchester, 2015). In 2009 the activity tracker of Fitbit Company was sold. In 2011 Fitbit improved existing product by adding an altimeter, a digital clock and a stopwatch, and since today still improving their products. In the same year on November, first generation of UP by Jawbone, an activity tracker released. As of 2012, lifelogging, "self-tracking" and "quantified self" keywords are observed to increase in interest articles. 2012 marked a year of unprecedented investments and research into the intersection of technology and fitness with products such as Nike Fuelband, The Fitbit One, and The Fibit Zip. 2012 was the year of crowdfunding, and the two biggest sites (Kickstarter and Indiegogo) each featured activity trackers among their most successful products. From this date on, it is observed that the products are diversified, new features are added and the accuracy rate in the measurement increased.

In the first article about quantified self named “Know Thyself: Tracking Every Facet of Life, from Sleep to Mood to Pain, 24/7/365” Gary Wolf (2009) who is one of the kickstarter of ‘quantified self’ movement with Kevin Kelly, a co-founder of Wired magazine conducted a mini research about himself, tracking sleep, exercise, blood pressure, mood, caffeine and alcohol consumption. He stated that they noticed in last two years their acquaintances start to ‘extract streams of numbers from ordinary human activities’. They are talking about a new personal data culture ‘Self-knowledge through numbers’ that emerges and indicates that it is becoming easier to self-track with new tools. In the same issue as Wolf's entry to the concept, Wired published four articles on quantified self-tracking focusing on specific areas: running, exercise, health and nutrition (Lupton, 2016).

In the "quantified self" search, 92 articles reviewed in more detail published dates between October, 2016 and June, 2009. It is realized that the articles are tagged with some key words pointing out the topic by the authors. These key words are specific to this search: design, business, gear, science, magazine, security (Table 2).

</tbody>
</table>

In addition, some articles are not marked with any keywords, and some articles are marked as sponsor content. In addition to article topics, some extra tags which address to subject headings of the article has been made (Table 3).
When the tables are examined, it is seen that the articles are most frequently marked with the 'design' key word. The word 'business' and 'gear' are closely following keywords. From this data, it can be read that authors express and associate the concept of 'quantified self' with these words at first glance. The articles tagged with the word 'design' appear to have been written about a wide range of products. In the case of 'gear', it seems to focus more on health related issues and activity tracking.

In the subject headings, it is intended to give clues about the subject product or concept is related to. While 'activity tracking' refers to products and applications that help the individual to retain data about his / her physical characteristics (step, running, cycling, blood pressure etc.), in the heading of 'health related issues', a more comprehensive follow-up (medical issues, woman issues, sleep tracking, etc.) is implied. In the title of 'other', articles about human beings and products, sociality related devices were taken into consideration. The term 'environment' includes agricultural, personal environment, carbon footprint and other environmental factors. In the heading of 'effects', the psychological and sociological effects of devices and applications on humans and society are discussed. The term 'personal tracking' refers not only to a specific feature of a person, but also to almost every feature that can be captured and transformed into a data.

The next detailed examination was made on the basis of "self-tracking" term and examined 18 articles that did not appear in other searches (Table 4 and Table 5).

It is seen that the articles that appear in this search are less both in number and in terms of subjects than in the 'quantified self' study. This term is often referred to as 'activity tracking', which is contextually referred to.

Lastly, 10 articles that appeared in the 'lifelogging' search which were not common to other subjects were examined for content (Table 6 and Table 7).

Looking at all three searches, it is clear that there is a correlation between the headings that point to the content of the articles. For example, the articles on which the concept of 'productivity' is highlighted include 'privacy issues', furthermore, it is also seen that the concept of 'privacy issues' is emphasized in the context of 'business' and in the articles that concern the production and consumption industry. Within this context, the devices that enable bosses to constantly monitor workers 'productivity' have been subject to many articles (Metz, 2015; Finley, 2014; Flaherty, 2014; Enthoven, 2013; Finley, 2013; Drummond, 2012). Seidenberg, in her article in November 2014, beside the transforming power of health data which is our most personal asset, acquired from genome-based therapeutics and diagnostics to pulse-monitoring and smart watches, asking the question of 'why should we continue to share it?'.

Wired articles are evaluating concept work and market-driven products in self-tracking practice. When you look at the contents, it is seen that a very large part of these articles are found with positive comments and predictions about the products. This positive approach is also a factor that allows the trend to develop and spread.
In particular, the articles on the subject of ‘privacy issues’ have particular support for the health issue. Although Seidenberg (2014) emphasizes privacy risks, she advocates the need for people to measure and share their data because of the potential for change in the health and pharmaceutical sectors and for the benefit of all humanity. Since 2009, the issue of health has become a subject for more articles each year.

In the development of the digitalized self-tracking trend, it can be said that it is actually a loop feeding between industry/academy and Wired magazine. In the first years of the magazine, some people have been doing experiments on themselves and do-it-yourself devices that you can follow on your own. In the magazine, especially in the first years following the introduction of the term quantified self, some of the experiments that some people have done on themselves and the do-it-yourself devices that you can follow yourself are discussed. Then, on this concept that emerged in the business world, products and services that serve this field have begun to emerge. Especially in 2012 and afterwards, the products that the industry reveals and the concepts that the academy put forward have begun to be the subjects of the magazine. The publication of the articles titled ‘Review’ and edited as an evaluation of certain products also started in 2012.

In fact, Wired magazine has a feature of being a medium to bring together both industry and academic environment and potential or existing users to discuss the needs and requirements. They are among the other media that serve this area because of the number of users they have reached. Because of those features, it can be said that Wired Magazine works as both trend indicator and trend innovator.

**Conclusion**

We experience times people try hard to get in shape both physically and mentally, and quantified self (tracking) devices provide an effective tool for motivating users toward lifestyle change and make data collection process easier. The ideas that could once be called utopian or science fiction have become commonplace nowadays. The products, which have emerged in order to make the individual better in physical, mental or emotional sense, have evolved in a form that can serve more different purposes over time. For example, Jordan and Pfarr (2014) refer to ‘a future where self-tracking harnesses a whole population’s data to identify patterns and make meaningful recommendations’. Another dimension is quantified workplace concept where an employer measure everything about their employees’ work lives which could raise privacy issues. When we are collecting information about ourselves unconsciously, the days when others gather information about us apart from our knowledge are not far away. From the perspective of Wired Magazine, they are publishing pioneering articles on technological developments due to concept of the magazine, conducting reviews on new products and applications and writing reports to anticipate new developments or negative situations in the future. The fact that in every month about 30 million people are accessing through wired.com in addition to the printed issues giving this media an important role.

It can be said that this digitalized self-tracking trend did not become mainstream, yet. The fact that the products available in the market are expensive enough to be regarded as luxury as discussed by Tso (2013), this issue actually indicates that this trend is not yet included in the trendy early majority, which is accepted by the early adopters. Furthermore the design process of tracking devices should be investigated to learn the underlying cause why these products are not very popular. One of the assumptions in design process that Munson (2017) indicates, “people will use personal informatics tools indefinitely” is worth to reviewing. Besides the dealing with resulting data, people find it hard to give the specific information to apps or gadgets
like what we ate that day. Difficulty of data entry process can cause users to not use the device continuously, longer periods of abandonment of the gadgets or don’t replacing when the device is broken down (Munson, 2017).

Another reason for not becoming mainstream is about dealing the resulting data. CEO of Lark Technologies indicated that more than 90% of tracking gadget users are not motivated by looking at the obtained data (Schüll, 2016). Munson (2017) also point out this issue in another assumption “More data are better”. He suggest that through a study that they have been doing with colleagues a way forward around the “minimum viable data” that can further a goal. Speaking of problem areas related to tracking devices will allow design process of devices to be modified in the future. It will be possible to increase the use of these devices day by day, especially by facilitating data entry and transforming the resulting data into a meaningful way that the user can apply the data actively.

On the other hand there are mobile apps, scales, and activity trackers that beam data they collect to the cloud are helping some doctors and hospitals keep tabs on their patients and inform treatments. Yet the variety and amount of data required to work with the healthcare industry will not be reached. Insurance and electronic medical records companies are investing in and partnering with tech outfits which encourage consumers to use activity and health tracking tools and upload the data to their platforms. The variety of products that have emerged to store and analyze our personal information actually brings with it the issue of privacy. The absence of any legal regulations on confidentiality of health data leads to the emergence of establishments that act as a marketplace for information. In addition to this, the amount and the diversity of data obtained allows to progress in academic and product development areas.

Abstract
Effective university-industry collaboration has become a major focus for governments in recent years. Universities are increasingly expected to play a greater role in the innovation system and evidence their contribution to economic development. At the same time, the growth in research quality assessment exercises makes it imperative that the excellence of research conducted in commercially-driven activities can be appropriately evaluated. This paper explores the challenge of reconciling commercially-focused activity and research quality assessment in design. Semi-structured interviews were conducted with thirteen experts including representatives from the design discipline, other applied academic disciplines, research quality assessment leaders and commercial designers. The interviews identified a number of barriers to demonstrating research excellence in commercially-driven projects. These were classified as barriers resulting from: the nature of industry/academic relationships; the nature of the project; and the nature of the research quality assessment. It is concluded that there is a need to build a simple, easily usable framework for assessing the research potential of commercially-driven design projects from the outset to ensure that the appropriate processes are put in place to communicate research conducted within them.

Keywords: Design, Industry, University, Collaboration, Research, Assessment.

“… Today, the boundaries between basic and applied research are blurring, and more and more fundamental research is conducted in the context of application...” (European Research Council, 2015); this can be seen as part of a move within the research environment towards increasing levels of applied output. About a third of scholarly submissions to the 2014 UK REF, Research Excellence Framework - a system used in the UK to assess research in higher education institutions-, were non-standard outputs, including performance, composition, design, artefacts, exhibition and digital or visual media (REF results, 2014).

Therefore, there is a need to evaluate non-standard academic outputs in any assessment of research quality is increasing. The process of understanding and disseminating research from non-traditional outputs is thus facing difficulties and one way to better understand the issue is to
try and identify these difficulties.

**Literature review**

Increasing attention is paid in universities to the development of effective industry/university collaborations. In many countries, universities are considered to be key contributors to wealth generation and economic development. The economic and social impact of universities on industrial innovation through creating new knowledge and educating the ‘future professionals’, has long been recognized (Cohen et al. 2002; Mansfield 1991; Pavitt 1991; Salter and Martin 2001) and policies are being developed that promote and sustain university-industry collaboration. (Dowling, 2015; Dooley & Kirk, 2007) Meanwhile, the role of design as a driver for innovation is also becoming more recognised. (Verganti, 2013). As such, design providers within universities are well-positioned to engage with industry.

In recent years, change in the Higher Education landscape across a number of countries in Western Europe, the UK and Australia has seen the integration of many art and design schools into universities. (Rodgers & Yee, 2016). There has been a long history of commercial activity within art and design colleges. Many designers were employed on the basis of their professional reputation and continue to practice both to maintain that reputation and to remain abreast of developments in commercial design. (Rust, Mottram & Till, 2007). More recently, however, designers undertaking professional practice within universities have been experiencing tensions between the need to evidence their contribution to industry with their contribution to the research quality of the university. (Kuys et al. 2014) Research quality assessment exercises are increasingly being implemented by governments across the world. In the UK, the Research Excellence Framework (REF) is the basis of research quality assessment and serves a number of roles: it contributes to the decision-making about the distribution of national research funding; it provides evidence for governments in setting national research priorities; it shows the outcomes of public investment into research; and it may be used by universities to inform their resource allocation policies (Stern, 2016; Ratcliffe, 2014). As such, it is important that design research is appropriately represented within research quality assessment frameworks to attract continued support and investment from universities and governments. Within the REF, research is defined as “a process of investigation, leading to new insights, effectively shared” (REF, 2011). The excellence of research is based on three main criteria: originality, significance and rigour. Originality in research is defined as “a creative and/or intellectual advance that makes an important and innovative contribution to understanding and knowledge”; significance as “the enhancement or deserved enhancement of knowledge, thinking, understanding and/or practice”; and rigour as “intellectual coherence, methodological precision and analytical power; accuracy and depth of scholarship, awareness and appropriate engagement with other work” (REF, 2011). To demonstrate research excellence, a commercial project must feature some degree of originality, significance and rigour, and moreover, the commercial partner must be willing to share evidence of this. Further, since 2014, the impact of research has played an important part in assessing research quality.

The changing higher education context coincides with shifts in the industry. There has been increasing attention paid in the industry to new forms of value creation from design. The rise of
participatory, user-centred, service, sustainable, socially-responsible and innovation management design in industry has given rise to the need for new skills in the design community that are more focused on new research and design processes. (Rodgers & Yee, 2016). Therefore, the range of activities that might be conducted by design practitioners in a university-industry collaboration has expanded enormously. To illustrate this, in 2013 design practitioners at PDR (an award-winning design innovation and research centre based at Cardiff Metropolitan University) undertook 369 projects with 69 companies, generating a turnover of £687,000. These projects ranged in time and complexity from simple CAD manipulations to large-scale projects that required innovative approaches to user research, concept development, mechanical engineering, design for manufacture, rapid prototyping, usability testing, in-house low-volume production, and management of the handover for full-scale production. In some cases, the knowledge required to undertake the work was readily accessible, based on the experience and training of a single designer, whilst in other cases the work required larger teams dealing with complex new problems that necessitated rigorous exploration for the creation of innovative solutions. It is clear that significant novel research may have been conducted within some of these commercial projects.

However, in practice it can be difficult to identify, evaluate and communicate research excellence conducted within a commercial project in any discipline. (Elmuti et al. 2005). To demonstrate research excellence, a commercial project must feature some degree of originality, significance and rigour, and moreover, the commercial partner must be willing to share evidence of this. Further, the discipline must provide some evidence of its broader impact. This paper explores the barriers to extracting research excellence from commercial projects.

Research methods

The study adopted a grounded theory methodology (Charmaz, 2006; Glaser and Strauss, 1967). Extracting research excellence from commercial projects was identified as the main process of concern, and stakeholder analysis was conducted to identify key viewpoints that should be represented in the study. The stakeholder group identified are presented in Table 1.

</tbody>
</table>
A big part in a research project is research assessment, and knowing about the administration process of the submissions to UK’s assessment exercise (REF).

The school of management, like art and design, has a great deal of work with the commercial and business world. This relationship, compared to the commercial design/design research one, can create many parallels to draw upon.

Sports education and practice are heavily reliant on theoretical work such as biomechanics and physics. The communication between practice and research is thus inevitable. Looking at this field’s practices and ways of communication can lead to a transferrable set of skills or methods to the design world.

Preliminary unrecorded interviews were conducted with representatives of the stakeholder groups to locate the main challenges. This process led to a number of interviewees and the relevant questions to ask. According to Charmaz (2006) the key elements of the grounded theory are the simultaneous involvement of analysis, data collection and the development of the theory during each step of the process, and the use of sampling as a tool for theory construction rather than population representativeness. Therefore, interviews were each transcribed almost immediately after, which helped in further understanding of the context, in focusing the next interviews, and in the choice of the next interviewees.

A semi-structured interview template was developed based on the findings and data collection proceeded through semi-structured interviews with thirteen experts with different perspectives on the relationship between universities, industry and research excellence.

Interviewees were drawn from applied academic disciplines (design, sport and exercise studies, business and management), university research and enterprise administration and Art & Design REF panel leaders (from two of the top 25 ranked art and design universities in the UK according to The Guardian’s University guide 2017: league table for art(2017). Interviews were transcribed and an open-coding method was employed in which the data were separated into segments and interrogated to identify common themes by three members of the research team. Three transcripts were coded by one researcher and the emerging themes were sense-checked by two other members of the research team. The analysis was used to further develop the theory and inform further interviews until no further themes emerged. The themes were reviewed and clustered to produce an affinity map of themes related to barriers encountered in evaluating, evidencing and communicating research excellence in commercial projects.

The identified barriers were clustered into three main themes: the nature of the
commercial/academic relationship; the nature of the project being undertaken; and the nature of the research quality assessment process. Table 2 provides an overview of the identified barriers for each theme.

Table 2: Barriers to identifying, evaluating and communicating research excellence in commercial projects emerging from expert interviews

Discussion

The nature of the commercial/academic relationship

While the value of the collaboration between academics representing universities and commercial stakeholders is indisputable, the increase in cooperation brings with it a rise in conflicts between the two fields. Commercial projects conducted within a university context have to manage a number of concerns related to commercial confidentiality. In some projects fear that the dissemination of the academic research component may jeopardise competitive advantage or intellectual property rights can influence the commercial partner’s willingness to engage or support the output. This is related to the level of trust that exists between the two partners. Talking about commercial partners’ willingness to give away information, J (2016) explained that “…even if they are going to allow you to publish, they will try to sensor what you are about to say, and that is a huge issue...”. If the trust and credibility of the researcher is not clearly established in the minds of the commercial partner, then the perception of the different objectives of partners can be a problem in establishing an effective relationship. L (2016) pointed the trust issue out, when he spoke about how hard it is for commercial partners to decide to let a research partner get involved; “Once they accept that they can’t develop this skill, maybe then a scientist comes in and does the research question and says ‘oh, these are the three options that you have. Then yeah they have to trust you, and know the information you are giving them are meaningful and correct’”.

The commercial partner may fear that the university partner will prioritise research outcomes over commercial needs. One interviewee cited this, explaining that the need to make research generalisable may lead a researcher to simply deploy an existing framework, rather than conduct the appropriate research for the situation at hand.

According to Kirk and Dooley (2007), trust in university-business partnerships are strengthened by longer relationships, increasing the likelihood that the commercial partner will engage in the development of research outputs. However, where new partnerships are being developed, or commercial partnerships are particularly lucrative, the opportunity to translate the commercial project into an academic output may be passed over, even if there is no chance of breaching confidentiality. There are, however, times when the ethical considerations can bring partners into conflict; examples were given of industry-business collaborations in the health and sports sectors that had revealed patterns of injury or ways of avoiding illness that the academic considered it essential to communicated to the wider environment, irrespective of commercial sensitivities.

The cost of research can also be a limiting factor. Time, financial cost and the way projects are scaled and justified differently in commercial and academic contexts are major problems faced in building effective university-business collaborations. Alongside concerns arising from potential loss of competitive advantage, overhead costs mean that the cost of working with universities on company-funded projects is relatively high. Commercial partners may be concerned that formalising the academic research component of a project will lead to longer projects and more incurred costs. This can lead to commercial partners limiting the form or extent of research conducted within a project prior to commencement which may, in turn, have an impact on research quality and validity. The problem that many commercial parties swipe under the rug,
that the time saved on research could have resulted in better product development. The StreetScooter and Raven the surgical robot are examples of commercial success facilitated by academic skills and inputs (Jones & Clulow, 2012).

The commercial environment can also affect the likelihood of being able to conduct academic research within a commercial project. Risk aversion related to the application of ‘unproven’ techniques can limit the extent to which a project can demonstrate new research. Risk aversion may also manifest itself in an unwillingness to communicate unsuccessful research activities. This does not sit well with the academic concept of impartiality. Acknowledging failure, and more, being given the space to fail makes an important contribution to a discipline. It challenges existing knowledge and helps to shape future research activity. However, when failure is translated into a dissatisfied client, customer or user then commercial organisations may not be inclined to bring it to the attention of a broader audience. Another cultural factor within commercial organisations that affects the research potential of collaborations is resistance to change. Companies that are unwilling to change may not adopt the outcomes of a project, making it difficult to evaluate effectiveness and evidence impact.

Communication between partners is a very common barrier to developing mutually beneficial commercial projects. In particular, the communication of the value of academic research to commercial partners can be very difficult at the early stage of project development. Where applied research is communicated through journal articles, the availability and accessibility of the information is a concern to commercial partners. Commercially involved interviewees in the project commented that there was often an expectation that their colleagues would read and fully understand academic texts. K, the business and management researcher stated that “... An American driven journal in operations management, the only 4-star journal in OM, and it is very quantitative, and it is written in a very academic style. Right, there’s a direct inverse relationship between that and the accessibility of that material to the practitioners, because they cannot understand what the they are talking about.” (K, 2016). The challenge of communicating important information and research value to multidisciplinary partners in projects is a common challenge. For example, in the medical field, the Critical Reading of Research Publications (CRRP) tool has been developed to help nurses to understand academic articles (Johnson et al., 1995).

The nature of the commercial/academic project

As previously discussed, university-industry projects can take a range of forms. The extent to which there is scope for original research within the project depends very much on the form that it takes. Unfortunately, academic relevance of commercial projects or commercial relevance of research is not always guaranteed. This is not to say that commercial projects that cannot be exploited for research outcomes are not valuable in their own right, just as both ‘exogenous’ (curiosity-driven) and ‘endogenous’ (market-driven) research have a place in the modern university (Dooley & Kirk, 2007). It simply means that there is no benefit of trying to evidence research significance in every commercial project. Equally, the enormous variety of different projects that may be conducted can mean that the outcomes of one project have limited transferability to other situations and contexts. If innovative research has been conducted within the project, it may prove challenging to prove the validation of the approach if a further case
of its application cannot be identified. Therefore, demonstrating rigour in research approach may be challenging. A related issue is the difficulty in **building the evidence base**. Processes, methods or inputs that have worked within one project can be used to show evidence of impact in one specific case; however, building an evidence base that supports the application of methods and practices in different areas requires a critical mass of projects. The **scale** and **speed** of projects can also limit their effectiveness as carriers of academic research excellence. Commercial organisations often have very different time frames to university-based practitioners. These differences are difficult to reconcile so designing a project that can deliver commercial and research benefits is challenging.

The nature of the research quality assessment process

Assessing commercial projects for their academic objectives is perhaps where the differences between the needs of the partners is made most obvious. **Academic metrics of success** include two elements: further grant funding and traditional research outputs. Academia is about producing and communicating knowledge, which is not usually the intended result of commercial projects. The loop of knowledge-creating-further-knowledge is not a cornerstone aspect of business; this lack of information sharing community within commercial design, works as a barrier to the evaluation of the research since there is little documented history to draw upon. The gravity of this problem is compounded when there is limited **documentation** of a project, and where the **accessibility of information** is at the behest of the commercial partner. A lack of documentation throughout any commercial or art project makes any future attempt to try and understand the research value, or try to communicate that research value, a much harder task. This is particularly problematic when academic practitioners are attempting to build the evidence base; the need to revisit the project may come several years after its conclusion. As such, communication of the rigour and significance of commercial projects through processes that rely on the **generalisability, quantification and validity of outcomes** can be very difficult. This highlights the difficulty in identifying **appropriate evaluation criteria** which is further compounded by the variety of outputs that can result from a commercial project. Assessing diverse outcomes for research quality is not a new challenge; about a third of scholarly submissions to the 2014 REF were non-standard outputs, including designs, designed artefacts, exhibitions, visual media, digital media, performances and compositions (REF results, 2014). However, assessment of non-standard outputs in the REF is heavily dependent on peer review and the institution’s reputation, which has led to claims of **subjectivity and bias**. In 2006, a European Commission review of university provision across member states concluded that: “...universities should be funded for what they do, not what they are...by focusing funding on relative outputs, rather than inputs”. (European Commission, 2006). In a recent assessment of university-based research across Member States conducted by the European Commission concluded: “evaluators may be influenced by their competitive pressures, including possible implications for work of their own, or that of their colleagues. They may evaluate research in terms of what they know, and therefore they can act as conservative ‘gatekeepers’” (European Commission, 2015).

In defining the **originality** of a commercial project, it is important to note originality can be evidenced in the REF by proving that the research output shows “empirical findings, new
arguments, interpretations or insights, imaginative scope, assembling of information in an innovative way, development of new theoretical frameworks and conceptual models, innovative methodologies and/or new forms of expression.” (REF 2011). As opposed to traditional research, in which researchers have 5000 to 10000 words to elaborate and explain their interpretation of how their output holds original value, artefacts have only 300 words. This, makes it impossible for some designers to communicate the research value in their work.

It is important to recognise that originality can exist in the process, in the communication between the partners or industries. Although it is tempting to consider commercial success and high sales as indicators to originality, originality is not necessarily a measure of commercial success, but can have a direct or indirect impact on the latter. Is incremental innovation original? In the commercial world, a small alteration made to a product can have a huge impact on its performance. Does that make the output original? Even more importantly, does this originality have a research value?

Researchers expressed a difficulty in defining rigour to a commercial partner; we could argue that this goes back to the resistance to change when a “way of doing things” worked just fine for years, even though it lacks rigour, why change?

Significance is defined by two factors Extent and reach. The different types of audiences (academic, art and commercial and ways to communicate research to them, as well as triggering the right audience) can affect the assessment of a project.

According to the interviewees Peer review has by far been the most used research evaluation tool, but it holds a lot of bias. When it comes to evaluating the rigour of any output, peer review is one main method. We believe the problem in non-traditional outputs might be that the methods undertaken tend to be the ones accepted by the client or commissioner rather than the ones acceptable to the reviewing process. The extent of the reviewer’s knowledge of a certain area as well and their subjectivity when reviewing a piece of work are crucial elements that play a role in the fluctuation of the assessment of significance using peer review. A major difficulty is in the ability of a reviewer coming from an academic context, to see the commercial significance and vice versa. Although originality is not necessarily represented by the market performance, in the cases where it is, using the market as peer-review can be hard to translate into structured academic evidence of significance.

The ability of the artists and commercial partners to locate their work within previous work or Prior Art is debatable, not all designers of managers have an academic background, and the ability to distinguish between the significance caused by the actual work itself, and the significance caused by external circumstances (like the influence of previous art on it for example). Poggenpohl (2015) argues that nowadays with focus on innovation, and the amount of information available and the attention to research, designers who are focussed on creating something new and on what comes next, designers ignore the fact that the past is the base of development.
Conclusion

Every year, a number of socially and economically impactful artefacts and products, carrying a load of research value, are produced and go unshared and unnoticed. The fixation on high research assessment exercises and their scrutiny when it comes to non-traditional research outputs holds researchers and practitioners from sharing that knowledge. In this paper we tried to generate a collective list of barriers and limitations based on the perceptions of a group of experts, to see where the problem really lies. Three areas of barriers were identified: Commercial/academic relationships, commercial/academic projects and research quality assessments. The scale of the projects (time and money), the communication between commerce and academia, the unclear definition of the different elements that characterise quality research, and most importantly, the fixation on producing research submit-able to research assessment exercises, backed by a list of other limitations, create this bridge academia has long been trying to cross.

This list of limitations will then be used to try and find ways to overcome those barriers. The solutions, when available, will later help in creating a framework or set of criteria that can support commercial and academic institutions bring out the research value lying in the background of impactful commercial and non-traditional outputs.

Authors Biographies

Dana Al Batlouni
PhD student at PDR, Cardiff Metropolitan University. Her background in marketing and international business management combined with her interest in design, led to her involvement in this research study. Dana is interested in the role commercial design can play in supporting academia, for more sustainable academic research.

Dr Katie Beverley
Senior Research Officer in Ecodesign at PDR, Cardiff Metropolitan University. Since joining PDR in 2014, Katie has been involved in university-industry collaborative projects with companies from a variety of sectors including furniture, fashion and automotive. Katie has a strong interest in the role that universities play in supporting innovation.

Prof. Andy Walters
Director of Studies at PDR, Cardiff Metropolitan University, Andrew has developed research interests that centre on applied research related to design practice. That is, Andrew is interested in how companies use design, and how that use of design can be improved through intervention at the organisational and government policy level. Thus, Andrew’s work is closely linked to Enterprise and Knowledge Exchange (KE) activity where meeting the needs of participating industrial organisations creates both research material and informs subsequent interaction.
Urban Planning in the Middle East: Analyzing Al-Tahrir Square as a Public-Political Space in Iraq

Rasha Al-Tameemi, University of Cincinnati, Cincinnati, United States of America, altamers@mail.uc.edu

Abstract

Al-Tahrir Square, surrounded by commercial crowded streets, financial headquarters, and governmental institutions is one of the most iconic squares in Baghdad. It is part of daily life for many Iraqi people due to its central location, which is characterized by busy roads with honking cars. In this essay, I am going to explore Al-Tahrir Square in Baghdad, Iraq as a venue of rebellion for Iraqi people. Since 2015, Iraqi people from diverse backgrounds have been gathering in the square to protest for their rights every Friday. It has been the site of many historical events in Iraq although it has been established as a social place. I will explore the sociopolitical significance of Al-Tahrir Square by connecting the history of the place with how it has been changed since 1961 when the Freedom Monument was first open to the public. The research addresses the urban landscape of Al-Tahrir Square and its transformation over time, taking into consideration the political issues that affect it. I will analyze policies and regulations that have discouraged people from gathering in the Square to prevent political threats to the government and suggest ways to create safer spaces and mixed used attractions, modify the natural landscape of Al-Ummah Garden to make it more connected to the Square, and revitalize the existing kaleidoscope for closer proximity to Tigris River.

Keywords: Al-Tahrir Square, Freedom monument, Al-Ummah Garden, Al-Rasheed Street, and urban planning

Al-Tahrir Square has a complicated history. It was a parking lot in the 1950s, but in 1961, it use shifted and it became the location of the Freedom Monument. This shift marked Al-Tahrir Square as evidence of the Iraqi people’s journey of struggle and victory that designated it as a symbol of a new era of liberation from British colonialism. It has always been selected as a protest site because of its location in central Baghdad, especially in the past when it was the focal point for social gatherings. Besides being accessible from both Al-Karkh and Al-Rusafa, the two sides of Baghdad, through the highways and bridges that shorten the distance, the Square has had a long history of political demonstrations and has become a symbol for liberation, represented by the Freedom Monument.
Research Methods

Urban Context

Al-Tahrir (figures 1-4) lies on the eastern side of Baghdad in area known as Bab-Alsharji (eastern gate). The Square has had and still has an important role in many revolutions, marches, and uprisings in Baghdad. It is called the Al-Tahrir, which in Arabic means “Liberation” in relation to freedom from British occupation and the colonial period. The Freedom Monument is located on the east side of the Square, and behind it is a garden known as Al-Umma Park or the Garden of Nation, while the Republic Bridge is located on the western side of the Square. To the left, this bridge is framed by the Tigris Primary School for Girls and the Al-Aqeeda High School for Girls, which were established in 1921. The right side of the bridge is marked by the former Turkish restaurant building, in addition to several bookstores including the Renaissance Bookshop (Al-Nahda Library). Republic Street1 runs along the north side of the Square, parallel to Al-Rrasheed Street. The southern side of Al-Tahrir Square leads to Al-Sadoun Street2.

Figure 1: Map of the area surrounding Al-Tahrir Square
Source: Google Earth

1 Republic Street, an old street that has been renewed to combine elements from traditional and contemporary architectural style, offers a public commercial scene with different markets including bazaars and retailers.

2 Al-Sadoun Street is one of the main streets in central Baghdad that houses popular medical clinics, travel/tourist offices, the very first cinemas (Sinbad and Victory), hotels, and bookstores. The street is named after Abdul-Muhsin al-Sadoun, former prime minister (1922-1929) who was involved in the anti-colonial political struggles of the time. Its development began in the 1930s when it was designed to be a posh residential neighborhood for the elite. Over the last several decades, however, it has been transformed into a commercial hub, with rich families having moved to quieter areas, thus inviting more blue-collar workers and low-income families into the area.
The urban landscape of Baghdad is characterized by a spontaneous compact fabric, and the “hierarchical” layout of streets and alleys ends with cul-de-sacs. The land use was mixed (commercial and residential) in the past, but commercial use dominates the city center today. From the 1930s to the 1950s, Baghdad witnessed changes in its urban planning system from a semi-circular growth to the modern-day linear expansion system on the axis of Tigris River. The political past along with the economic progress gave way
to the construction of the street grid system, followed by schematic urban development. The First Modernism era in Iraq began with the establishment of Al-Kifah, Al-Khulafa, and Al-Rasheed streets. From the 1960s until the 1970s, Baghdad has mostly adopted modern architecture ranging from commercial, administrative, and governmental multi-storied buildings to private residential houses that showcased the experiences of local Iraqi architects who had studied abroad (Elsheshtawy, 2004, pp. 63-65). This period also witnessed a turning point in modern architecture, which is reminiscent of Baghdadi heritage through its search for identity unique to the Iraqi Architecture. This led to the establishment of the Freedom Monument for Jawad Saleem (pioneer of modern art in Iraq) in Al-Tahrir Square. Monumental architecture reflects architecture and urbanism, which are used to construct symbols of national identity (in wake of anti-colonialism) through traditional symbols or modern style, depending on the sociopolitical dimension of the authority (people in power) or government (AlSayyad, 1992, p. 9, 15). Thus, cities play an important role in creating symbols and identities besides a product of the dominant culture (AlSayyad, 1992, p.17).

Freedom Monument

Freedom Monument reflects people's voices and was designed and built by Iraqi artist and sculptor, Jawad Salim. In 1950s, Baghdad witnessed developing art movements and was influenced by Baghdad Modern Art Group (Jamat Baghdad lil Fann al-Hadith). Many Iraqi artists were affected by European art, especially during WWII where soldiers from Europe and Poland (who were also painters) encouraged Iraqi artists to reject their artistic norms and invent individual paths (read: Expressionism). Thus, the Iraqi art group of pioneers (Al-Ruwad) emerged, including artists and sculptors Faiq Hassan and Jawad Salim, who developed a national style illustrating traditional life and nature. This period was marked by the Monument of Freedom (Nasb al-Hurriyah) in downtown Baghdad as a masterpiece of Jawad Salim embodying Arabic, Sumerian, and Babylonian features using western style and materials. The artists of this period wanted to modernize Iraqi heritage and tradition through new vocabularies and forms (Bernhardsson, 2008, pp. 85-86). According to Magnus (2008), “Baghdadi artists often left trapped between their social connection to Westernized elite of Iraq and their romantic, nostalgic visions of the local people and places they painted in country scenes or who represented the plight of the working poor in their poetry” (p. 86).

The structure of the monument extends to a distance of fifty meters long and ten meters high; the bottom edge of the monument rises six meters from the ground. It exceeds the height of all the sculptural works of Jawad Salim. The structure of the monument frames the entrance of Al-Umma Park (Garden of Nation) in a similar manner to that of the ancient Assyrian gates. This gate’s structure is designed to be a horizontal elongation

3 Jewad Selim (1919–1961) was an Iraqi painter and sculptor who studied sculpture in Paris (1938-1939), Rome (1939-1940), and London. He previously worked in the Department of Antiquities that gave him the knowledge of per-Islamic and Islam art. He then became the head of the Sculpture Department at the Institute of Fine Arts in Baghdad until his death in 1961. He also founded the Jama'at Baghdad lil Fen al-Hadith (The Baghdad Modern Art Group) and the new Baghdad School of Modern Art and is credited as the most influential artist in Iraq's modern art movement.
with the lack of geometrical lines and surfaces to emphasize the content of the monument. Rifat Chadirji took the idea of this structure from the protesters’ banners, which they used to support the July 14th Revolution of 1958. Chadirji told Salim, “Let us make another type of banner, which lives forever!” (Jabrā, Jabrā Ibrāhīm, 1974, p. 74-76). The monument consists of fourteen parts of discrete casted bronze. It denotes the history of Iraq in the ancient and modern times. Salim was inspired by the ancient Iraqi art of cylinder seals, in which a sheet of clay was rolled over a series of engraved images, creating a long and harmoniously balanced banner. The artist chose protruding sculptures because it is characteristic of Mesopotamia since the Babylonian and Assyrian Ages until the late Abbasid era (Jabrā, Jabrā Ibrāhīm, 1974, p. 76). The Iraqi government gave Salim all the freedom of expression to design the monument after the July 14th Revolution of 1958, so he went to Florence, France to work on this sculpture in the beginning of 1959. Muhamed Ghani Hekmat, who was his student at that time and spending his last year of studying sculpture in Rome, helped Salim in work of Freedom Monument (Jabrā, Jabrā Ibrāhīm, 1974, p. 80).

The number, 14, represents the 14th of July Revolution, so the number has acquired mystical value besides that this number is the double of number 7 that has symbolic meaning of victory engrained in people’s minds. These fourteen parts contain twenty-five figures, notably a horse and an ox. Most of these figures are eight meters high. That results in verse of Arabic poetry after all the sculptures had been arranged to be read from right to left. Although each sculpted figure is a one part by itself, each one connects to the other in a coherent context to give the whole meaning of the monument, which highlights aspirations of Iraqi freedom since Ottoman Empire and the sacrifices made by people to gain it (Jabrā, Jabrā Ibrāhīm, 1974, p. 82). Soon after, Salim had a heart attack and died on January 23, 1961, when he was 42 years old, before finishing the structure that was completed by his wife Lorna, sculptor, Mohammed Ghani Hikmat, and architect, Refaat Al-Chaderchi. The monument had been finished according to the specific date, and the opening ceremony was on July 16, 1961 (Jabrā, Jabrā Ibrāhīm, 1974, p. 85).

The fourteen individual panels of Freedom Monument start from the right to the left (like the Arabic language):

Figure 4: Freedom Monument and its individual panels
1. The Horse

The monument reads from right to left and begins with the unruly movement of four men trying to catch and pull a horse that strongly jerks its head. The horse is one of the most distinguishable symbols that represent strength, nobility, and masculinity. In the figure of the horse, Salim wanted to symbolize the morning of the 1958 Revolution on 14th of July where people gathered around two statues in Baghdad and pulled them down. One of the removed statues was of the British General Moad on horseback in front of the British Embassy because it represented colonialism. The second statue of King Faisal on horseback was near the broadcasting building. The first panel of the four men tugging the horse represent the Iraqi people, where three of them seem to try to catch the horse while the fourth figure rides the horse and raises a sign to declare the beginning of the revolution (Jabrā, Jabrā Ibrāhīm, 1974, p. 136).
2. Pioneers of the Revolution

In this panel, the movement of the figure continues toward the center of the monument to express the Revolution. Iraq’s long history has witnessed many revolutions against oppression, so this figure flowing out of the scene of the man-horse struggle symbolizes the pioneers of the revolution who raised their banners high in declaration of independence. Salim chose this figurative representation to exemplify people’s rebellions in Iraq against injustice, both past and present (Jabrā, Jabrā Ibrāhīm, 1974, p. 138).

3. The Child

Salim presented the hope and future through the sculpture of a child who raises both of his innocent hands as though blessing human work and effort to produce a future of
freedom and justice. The child is the only sculpture that Salim constructed in three-dimension, unlike the others that are all bas-relief sculptures. Since Salim studied in Europe and was influenced by the art of the Italian Renaissance, he interpreted the sculpture of the child as Jesus Christ referencing the ideas of resurrection, new life, innocence, human love, and sacrifice (Jabrā, Jabrā Ibrāhīm, 1974, p. 140).

Figure 8: The crier

4. The Crier

Salim chose to emphasize the important role of the Iraqi woman in rebellion and uprising. He embodied the woman according to the traditional way Iraqi women dress and react during tragic circumstances, where they rise above their abayas (cloak) to wrap the upper part of her body and then starts to cry and wail in sorrow for grievous events (Jabrā, Jabrā Ibrāhīm, 1974, p. 142).
5. The Martyr

In this sculpture and the one that follows it, Salim wanted to present the tragedy of the bereaved mother who is crying for her murdered son while surrounded by other women to reflect the image of the martyr, a figure that represents sacrifice and grief (Jabrā, Jabrā Ibrāhīm, 1974, p. 144).

6. The Mother and Son

Here, Salim expressed the dearest relationship in life through the compassion of the mother to her child where she envelops him as though an impervious wall, a gesture that signifies permanence, protection, love, and determination. This sculpture and the preceding panel emphasize not just the theme of the mother but also life and death, or in
other words, death in the sake of life. They represent the meaning of sacrifice and redemption (Jabrā, Jabrā Ibrāhīm, 1974, p. 146).

7. The Prisoner-Thinker

This section consists of two connections: first is the prisoner-thinker whose right hand rests upon the bars conveying the power of the mind, which despite the confinement, can one day be emancipated and free when the revolution serves justice. The second part denotes the citizen who supports the thinker with the help of a soldier whose leg comes out of the successive panel. The soldier reaches out to help the citizen destroy the prison bars that surround the mind during the revolution to achieve freedom (Jabrā, Jabrā Ibrāhīm, 1974, p. 148).
8. The Soldier

Salim executed the broad and powerful movements of a soldier where all their muscles are used to destroy the prison’s bars from every direction. The body of the soldier emerges from the neighboring citizen panel where their hands support each other. The sun above the soldier’s head symbolizes the day: a sign of the shining through. In other words, the sun rises above the brave soldier as their steps conquer evil (Jabrā, Jabrā Ibrāhīm, 1974, p. 150).
9. The Freedom

Here, Salim represented freedom as a woman holding a torch, in Greek style, and she exudes the feeling of ecstasy, elevating her into the sky. When Salim was questioned about the absence of the woman’s feet, he answered, “The feet would keep her on the ground while I want her to fly high” (Jabrā, Jabrā Ibrāhīm, 1974, p. 152).

10. Peace

In this sculpture, Salim exemplifies tranquility, the human dream on the earth, which is in contrast to the previous panels. In this part, the prison bars have transformed into tree branches, taut faces from pain have shifted to the quiet and restful face with two braids, and the dress flows on the figures body as the river flows. Furthermore, the pigeon represents Baghdad, a place full of pigeons, especially in its mosques (Jabrā, Jabrā Ibrāhīm, 1974, p. 154).
11. Tigris and Euphrates Rivers

Salim symbolized the two great Rivers of the Tigris and Euphrates with three Iraqi women: the one on the right rises high like the palm tree with its fronds spread around her head in representation of the Tigris river (in Arabic, Dijla means palms). The second figure on the left is a pregnant woman who holds wheat spikes to represent the Euphrates river (in Arabic, Furat means fertile). The central figure is a young woman who holds the Iraqi bounties above her head, embodying the tributaries of Tigris and Euphrates (Dijla and Furat). This panel represents the harmonious moment of the monument overcoming the violence of the revolution and the reassurance of the bounties of the nation where palms and rivers flourish (Jabrā, Jabrā Ibrāhīm, 1974, p. 156).
12. Agriculture

In this panel, Salim depicted two men who represent an Arab and a Kurd, leaning on a shovel symbolizing the faithfulness to the Iraqi soil. These figures have strong solid hands because these are the hands that toil and plant, and the figures are bound together with love. One of the heads is symbolized as an Assyrian type to refer to the cultural continuity of Iraq. The two men in this section parallel the neighboring panel of two women in form and gesture (Jabrā, Jabrā Ibrāhīm, 1974, p. 158).
13. The Ox

The ox is an ancient Iraqi symbol referring to masculinity, fertility, and strength. In the modern era, the ox represents the livestock that characterizes Iraq. Moreover, the ox on the far left creates a balanced image with the horse on the right (Jabrā, Jabrā Ibrāhīm, 1974, p. 158).

![The ox image](http://aloushaa88.blogspot.com/2011/07/blog-post_21.html)

Figure 18: The industry

14. The Industry

Finally, the laborer/worker symbolizes industry and production. The laborer stands tall and strong in hope for a better future in the name of achieving freedom, spreading justice, and hope for all citizens to contribute to the rebuilding of Iraq (Jabrā, Jabrā Ibrāhīm, 1974, p. 158).

Al-Ummah Garden

Known as the Garden of King Ghazi when it was established in 1937, Al-Ummah Garden is one of the most important areas in Al-Tahrir Square. After the July Revolution of 1958, this garden has witnessed many improvements such as the construction of lakes and the planting of various trees. Its name changed to Al-Ummah Garden, meaning Garden of Nation. This park is considered part of the nation's center and cultural heritage of Baghdad because it contains a number of commemorative monuments including the Freedom Monument, the huge mosaic by the Iraqi artist, Faiq Hassan, and the Mother Statue by the Iraqi sculptor, Khalid Al-Rahal. Unfortunately, this park also witnessed destruction, especially after 2003 due to the numerous car bombings and explosive devices in addition to a long period of neglect. However, the Secretariat of Baghdad

---

4 Al-Ummah Garden is framed by two of most important artistic pieces in Iraq, one is the Freedom Monument by the artist and sculptor Jawad Saleem, that faces Al-Tahrir Square and the other piece is the Large Painting of the Iraqi artist Faiq Hasan that faces Al-Tayaran Square. Both of them established after the 14 July Revolution 1958.
improved the park and reopened it on December 25, 2008. Despite this improvement, Al-Ummah Garden has neither completely recovered nor retained its audience and public life that it used to have in the 1970s. It suffers because of the unstable political situation in Baghdad and the decrease in city safety. Many aspects should have been addressed a long time ago, like the continuity with the river, which is within a mile of the park that can create active access and revitalize the whole area environmentally, socially, and economically.

Al-Rasheed Street

Al Rasheed Street is one of the oldest and most famous streets in Baghdad, known during the Ottoman rule as Khalil Pasha Avenue. Khalil Pasha was the governor of Baghdad and the commander of the Ottoman army who ordered to expand and modify the road from the eastern gate (Bab Al Sharki) to Bab Al Muatham and named the street under his name. This street was established according to military reasons to facilitate the movement of the Ottoman army and their carriages. It is considered the first straight street within the organic traditional fabric of Al-Rusafa Baghdad, which was established during the end of the Ottoman reign. It is also known as New Street and was later named Al Rasheed Street in late 1920s. According to Caecilia (2015), in referring to the British traveler, Richard Coke, this street was implemented in one night because it was against the will of Sunni Awqaf that resulted in demolition of close to 700 houses (p. 201). The work on this street was critical because it collided with the oppositions of religious people of Baghdad when they realized that the implementation of straight street could lead to demolish the Marjan Mosque, located on the road, in favor of the integrity of the street. The street also collided with the interest of powerful people and foreigners whose properties had been protected under foreign franchises. Thus, the demolition started with the poor properties and the absentee properties that did not have heirs. The work was performed by German military engineers who were in partnership with Ottomans and then between 1915-1916, Ottoman opened Rasheed Street to facilitate movement between warehouses and military offices during WWI. Caecilia (2015) analyses Al Rasheed Street as “another case of civic space subverted to a military agenda by facilitating the rapid crossing of the city from southern gate towards the northern sectors, where various military and governmental facilities were situated” (p. 21-22).

Al Rasheed Street had positive commercial effects on the neighborhoods and area around, which included Souk Al-Saray, and it is considered one of the most important streets in Baghdad (Caecilia, 2015, p. 21-22). During WWI, the eastern side of Baghdad al-Rusafa developed after the establishment of al-Rashid Street as Commercial Boulevard along the Tigris River (Bernhardsson, 2008, 84-85). Al Rasheed Street has ancient historic mosques, including Al Haidarkhanh Mosque built by Dawood Pasha in 1819, in addition to Margan Mosque, Hussein Pasha Mosque, and old markets (souk) such as Souk Haraj and Souk Al Saray. At the end of the nineteenth century, few modern thoroughfares (bridges) were designed during the colonial period, and the first one was established in 1869-1871 to connect the suburbs of Karkh and Kadhimiya in the west side of Baghdad to Al-Rusafa in the east side. In 1910, Al-Nahar Street was opened along the east bank of the river, which influenced the administrative center around it (Caecilia, 2010, p. 21).

Disscusion

Urban Analysis of Al-Tahrir Square

Caecilia Pieri (2015) suggests that the “urbanism visions of Baghdad as the capital city of Iraq were mostly imposed from above, first by colonial powers and later by local governments with their own political and ideological agenda” (p.199). So, Caecilia chronologically categorized the urban form of Baghdad according to the political power that ruled Iraq, starting from colonial urbanism under late Ottoman rule and British Mandate (1870s-1930s), regulation urbanism in independent Iraq (1930s-1950s), urbanism that influenced by the beginning of World Bank (1950s), urbanism after the Socialist expansion as a territory for Cold War (after 1965), urbanism that conveys the National Identity in the context of Iraqi Arab leadership (1980s), and today, urbanism in Post-War context (Caecilia, 2015, p. 200-207). According to the two approaches adopted by Camillo Sitte recommending focus on the visible form and the public use of urban environment, Al-Tahrir Square’s area follows the former approach while lacking human-environmental and behavioral relations approaches and public design participation (Jarvis, 1980, p. 50).

Three of the problems that Allan Jacobs and Donald Appleyard (1987) proposed in their manifesto were poor living environment, giantism, loss of control, large-scale privatization, and loss of public life in the area of Al-Tahrir square (p. 114). Unfortunately, this central area of Baghdad has lost a huge percentage of its residents, in part due to the inadequate environment that forced many inhabitants to sell their homes, which transformed to stores for the companies or commercial shop owners.
Sitte (1965) emphasized that city planning should consider the interaction between public buildings and open spaces to activate public life. He also emphasized that the center of plazas should be kept free and not blocked by monuments that would interfere with the view of buildings (p. 152-159). In the 1950s, Al-Tahrir Square was just a parking lot while in the 1960s, it was transformed into a functional plaza. Then in the middle of the 1970s, a tunnel was established to cross the middle of the square and ease vehicle movement. This process was against the principle of Sitte, but it also activated the square through construction of two levels, where the lower level contained small shops, barbers’ shops, and small banks. Al-Tahrir square witnessed a noteworthy transformation of its function over time, but regrettably, due to the unstable political situation, the lower level of the square deteriorated and was then abandoned. Today, the shops are owned by commercial businesses, and the green areas are overgrown with huge trees that block visual access. Therefore, today when many demonstrations and protests happen, people use the street around the square and near the Freedom Monument. Al-Tahrir square becomes more an ornamental part of the city than functional.

Sitte (1965) further specified that fountains and monuments have their meaning and history, which necessitates their placement by aside from the middle of the square, taking...
into consideration the orientation of the monument to the streets (p. 160-162). This is what makes Freedom Monument an ideal memorial place.

According to Jakob Skovgaard-Petersen (2001), there was an increasing interest in streets and squares as public spaces during the first half of the twentieth century due to their role in transferring the style and the language of the buildings and cities to people, which were often designed to express the national identity (p. 14). In the 1970s, Al-Tahrir Square played a vital role in social communication due to its location that connects Al-Saddun and Republic streets, two of the most important streets in Baghdad, in addition to the Republic Bridge that links Al-Rusafa and Al-Karkh, the two sides of Baghdad. Kevin Lynch (1960), in *The Image of the City*, identified three aspects of the environmental image: identity, structure, and meaning (p. 8). The first two aspects require recognizable entities and patterns of relations achieved by the physical features of Al-Tahrir Square, while meaning is achieved through the Freedom Monument with its historical and cultural significance in the collective memory of Iraqis and evocation of emotions of belonging to the place. Lynch (1960) wrote, “A vivid and integrated physical setting, capable of producing a sharp image, plays a social role as well. It can furnish the raw material for the symbols and collective memories of group communication” (p. 4). Therefore, a public-built environment is the unification of physical and behavioral patterns where streets can strengthen social communication in a meaningful public space.

The pedestrian movement in the area of Al-Tahrir Square has been affected negatively by the traffic of cars, which has also led to the deterioration of small businesses that largely depend on foot traffic. In the urban experience, pedestrian movement would permit economic, social, and cultural exchanges because in most cases, walking would not be for one purpose, but to also stop to buy a newspaper, water, talk to a neighbor or colleague, for window shopping, or have a drink at a pavement café. Pedestrian paths encourage people to stop and spend time within the space while car circulation would end in the garage (Carmona, 2003, p. 201-202). Conrad C. Kickert (2015) in “Active Centers - Interactive Edges” mentions that “More specifically, an open, interactive relation between buildings and public space at the ground floor is a crucial factor in making urban environments walkable, both from the standpoint of function, safety, and experiential quality” (p. 27). Hence, walkability is important in creating comfortable, sociable public spaces that Al- Tahrir Square used to have before the increase of roads and traffic congestion. Moreover, there is no longer night life in the area of Al-Tahrir Square due to the types of businesses that exist, which are day businesses, operating mostly from 7am to 7 pm. While in the past, this area used to have luxury restaurants, bars, hotels, cinemas, and theaters that played a vital role in the public life of this area. Allan Jacobs and Donald Appleyard (1987) assert, “The most important public space must be for pedestrians, for no public life can take place between people in automobiles” (p. 119). That agrees with Jacobs’s perspective that the mixed-use area, which results in a mixture of users at different times due to the various time of occupation in the surrounding buildings, would assure constant use in the neighborhood (Jacobs, 1961, p. 96-97).

During the reign of Ba’th party, Al-Tahrir Square did not witness any positive changes. A road was built to divide the Square into two halves, having a negative impact on the
social function of the Square through giving priority to car traffic over the social space that it previously provided. This clearly indicated that the government intentionally neglected the Square as part of a political agenda to first bring down the curtain on the era of freedom to present its power, and secondly, to divide any public space where people could gather to demonstrate or share their political perspectives. These policies have not only led to the decline the public space of Al-Tahrir Square, but also the Baghdad civic center, which drove many people to leave this area, especially the residential parts because it became a business area dependent mostly on vehicular traffic and flyovers with limited pedestrian movement after work hours.

According to Caecilia (2015), Baghdad’s urban form during the reign of Saddam Hussein focused on creating the image of grand capital. She says “Foreign and Iraqi architects were given the mission of transforming this political agenda into a monumentalized Baghdad, emphasizing the direct relationship between politics and built form” (p. 207). In another word, the urban development of Baghdad (1979-2003) has responded to the political agenda which symbolizing Saddam’s power over the country rather than addressing the real urban requirements and the increased population.

Politics and Public Space of Al-Tahrir Square

Comparing the concept of public spaces from western and eastern perspectives and their origins, it can be stated that both had a political agenda. Robert Saliba remarks that during the 18th and 19th centuries, Europe witnessed urban changes through emergence of the bourgeois city and transportation:

Underlying this society of spectacle was the military agenda of controlling of public space as a potential setting for demonstrations and political contestations. Transferred to the colonial context, either through the superimposition by mandatory powers or self-imposed modernization by local rulers, formal squares retained their agenda of military control (mainly of the indigenous population), however they redefined the conventional understanding and practice of open space in European provincial territories extending from North Africa to the Levant. (Saliba, 2015, p. 213).

Earlier, the concept of public space in Middle Eastern cities, especially in traditional Islamic cities, used to be connected to institutional spaces due to the integration of the political and religious in mosques. Then, public space changed to be a space for proliferation of democratic dialogues and political protests (Saliba, 2015, p. 213).

Cuthbert (2004) considers public space as an ideological instrument of capitalism because it can be commodified and sold like other resources in favor of social reproduction (p. 2-3). Although there are opportunities for political criticism and opposition, the right of speech in these spaces is not clear enough. When public space is defined as the shared world where people can engage with one another and see themselves through the eyes of others, then free speech becomes an important characteristic for these places in which to argue, discuss, feel sympathy, agree, and refute. This democratic environment is essential for minorities to present and convince the majority to support their diverse perspectives (Kohn, 2003, p. 2-3)
According to the interpretation of Henri Lefebvre (1991), space is defined as perceived (spatial practice), conceived (representations of space), and lived (representational spaces) (p. 38-39). He defines the perceived space as that “which embraces production and reproduction, and the particular locations and spatial sets characteristic of each social formation” (1991, p. 33). This can be reflected in the physical place of Al-Tahrir Square in terms of buildings, monuments, and works of art to reflect the reality of spatial practices. The conceived space means the representations of space. This definition has varied across the historical timeline of Al-Tahrir Square. It was a free public space for social gatherings during the 1960s; during the 1970s, it started to be controlled indirectly through urban guidelines by addition of the tunnel in the center of the space. Though it created commercial spaces in the lower level of the square, the goal was to divide the coherence of the space to prevent people from gathering, which might lead to protests that threaten the security of the government. During the reign of Saddam Hussein, Al-Tahrir Square was intentionally neglected by the government, though it could not be destroyed because of the people’s sympathy for the 17th of July Revolution 1958, which represented an era of freedom and thinkers. During the 1980s until 2003, this square, like all other public spaces, was surveilled by police to prevent any kind of congregation that might shift to demonstration. After 2003, this square was emancipated politically but has still not fully recovered socially despite the slight developments that the surrounding areas of the Square and Al-Ummah Garden have witnessed over the past few years. The representational space, according to Lefebvre, is the lived space through its connection with a system of non-verbal symbols, signs, and images. He described this space as “This is the dominated – and hence passively experienced – which the imagination seeks to change and appropriate. It overlays physical space, making symbolic use of its objects” (Lefebvre, 1991, p. 39). This is what Al-Tahrir Square represents today, especially after the demonstrations that have started every Friday since 2015, where the political discourse unifies people from different backgrounds, religions, and sects in the public sphere. Such demonstrations are an instance of using public spaces to ask for people’s right to better services, economic reforms, and de-corruption. Though there are many obstacles to these demonstrations, such as blocking many streets in Baghdad and prohibiting using cars to pass, this forces people to walk long distances that not everyone is able to do. Recently, members of police authorities, related to people in politics, started to arrest leaders of civil organizations leading the demonstrations so as to force people to retreat from their goals. Figures (36) -(39) illustrate the people around Al-Tahrir Square, and the blocked streets and bridges that lead to it and how police prevent people from reaching the square.

Eric Davis (2009) in his essay, "The Historical Genesis of the Public Sphere in Iraq, 1900–1963: Implications for Building Democracy in the Post-Ba’thist Era," points out that the interest in the approach of civil society in the Arabic world is the result of three political factors that happened within the late 1980s and 1990s. The first factor is the collapse of the dogma of pan-Arabism after the Arab–Israeli War in 1967. The second factor is the spread of Islamist political movements during the 1970s such as the one in Iran that succeeded in establishing the Islamic republic after the overthrow of Shah Mohammed Reza Pahlavi in 1978–1979. Finally, the third one is the crash of the Soviet Union in 1991, which was ally to the East that failed to achieve the democratic freedoms
in many Arabic countries. This resulted in the re-examination of the ideologies of pan-Arabism and radical Islam by Arab intellectuals (p. 390-393).

Digital public spaces also have a significant role in these demonstrations, especially Facebook and Twitter, to schedule and regulate demonstrations among activists and to inform general public of the demonstration. The participants then publish what happened at the sites to update others about the latest circumstances and conditions. Saskia Sassen (2011) in her essay, “The Global Street: Making the Political,” analyzes the uprisings of the Middle East and North Africa from an urban perspective and accentuates the concept of the global street that is a vehicle for making social and political claims and demonstrations as part of global modernity:

I think of the space of ‘the street’, which of course includes squares and any available open space, as a rawer and less ritualized space. The Street can, thus, be conceived as a space where new forms of the social and the political can be made, rather than a space for enacting ritualized routines. With some conceptual stretching, we might say that politically, ‘street and square’ are marked differently from ‘boulevard and piazza’: The first signals action and the second, rituals. (Sassen, 2011, p. 273-274).

Kohn (2004) states that there is a theoretical agreement for free speech, but on the other side, there is also a fear of being exposed to unfamiliar ideas and unwanted responsibilities. Thus, privatization of public space would be the solution for those who want to protect themselves from political provocations (p. 3-4). This would be the next step in an approach that many people fear.

Conclusion and Recommendations

An exploration of Al-Tahrir Square in Baghdad, Iraq as a venue of rebellion and site of many historical events in Iraq, as discussed in this paper, points out its sociopolitical significance and transformation over time as a public-political space. Thus, for urban design to be successful, it should have a mixture of physical form, both townscape and landscape, lively public life through mixed-use of land and pedestrian activities, and finally meaning through cultural symbolism that provoke collective memory and a sense of belonging to place. In Al-Tahrir Square, we need to focus on:

1. Creating safe and comfortable places for people by offering choices and social and visible attractions
2. Work with the landscape of Al-Ummah Garden in terms of nature, climate, landform and ecology, and energy conservation
3. Encourage mixed use spaces with a variety of sizes and types
4. Support connection (visual and physical access, walkable interesting paths, scale of walking, cycling and automobile)
5. Design to accommodate the change (flexibility in use of public buildings and public use could be personalized over time, allowing growth and additions)
6. Preservation of historic buildings and parts of the urban fabric that exist in the residential area, and
7. Plan open accesses and connections with the Tigris river, which is just about one mile away.
Our connections with places should be like our relationships with other people. The place that we need is what Relph (2013) envisioned: “a place is a piece of the whole environment that has been claimed by feelings” (p. 120). This conveys the comprehensive concept of a place that consists of natural and human-made structures and functions that would allow people’s experiences to create new meanings and identities in relation to the place and then inculcate in them a strong sense of belonging.

Abstract

This paper explores the findings of a study into the telecommunications environment in Mongolia. It was hoped that an effective self-learning resource for the prevention of developmental dysplasia of the hip (DDH) in infants for distribution to parents in that country could be created and evaluated using these findings. Based on a field survey conducted in Mongolia, the most effective format this resource should take was identified. A prototype was created that featured video taken from both a third-person and parent’s (first person) perspective. After further evaluation, this prototype is to undergo revisions that will be assessed in Japan and Mongolia before a final version is distributed utilizing information and communication technologies (ICT). It was found that a visual message that did not rely on written language was the most effective means of communicating the desired message. With input from nursing staff in Mongolia, the Sapporo City University School of Design and School of Nursing came to leverage their respective strengths to create an effective prototype that will be used as the basis for a resource for relaying this preventive information to the target audience.

Prototyping, Evaluation, ICT, Language Barriers, Health, Self-learning

Background

Current Situation in Mongolia and Japan
The traditional method of swaddling infants, where arms and legs are extended and immobilized, is still common in Mongolia. This practice helps newborns stay warm and allows for them to be more easily carried around – beneficial in Mongolia with its harsh natural environment and where nomadic herding is a major industry and way of life. However, swaddling a newborn may lead to the abnormal formation of the hip joint and is a contributing factor to the onset of developmental dysplasia of the hip (DDH). Tightly swaddling newborns was also formerly practiced in Japan, as was placing them in traditional basket cradles to restrict the movement of the lower body. The incidence of DDH was higher when these techniques were more widely used. Measures to detect DDH at an early stage were incorporated into regular infant health checkups in the late 1960s. As a result of this and a public awareness
campaign to prevent DDH, the number of cases in Japan was dramatically reduced.

Conceptualization of Resource Distribution
Between 2013-2015, the Sapporo City University School of Nursing supported various training initiatives and the creation of childcare guidance material related to the prevention of DDH at the National Center for Maternal and Child Health Mongolia (Ulaanbataar). While moderate success was achieved through these efforts, the necessity to expand training throughout the country to those living nomadic lifestyles on vast steppes became a topic of discussion. It was expected that information and communication technologies (ICT) could provide a promising means of delivering training in preventive care to parents (primarily mothers).

Study Aims/Method

Study Aims
This study was aimed at creating and evaluating learning resources for disseminating DDH preventive care measures targeted at parents of newborns in Mongolia utilizing ICT and so on with the following objectives in mind:

1. Basic survey on the current state of communications in Mongolia
2. Trial of ‘DDH Preventive Care’ self-study material aimed at parents
3. Creation of prototype utilizing ICT
4. Conduct of hearings in the field and evaluation of prototype

Study Method

With the view of utilizing ICT, etc., to leverage the achievements obtained by the School of Nursing up to the end of FY2015 in the creation and distribution of learning resources, it was decided that the study proceed as follows:

**Study on current state of ICT in Mongolia.** Among developing nations, the infrastructure for mobile communications is often at a more advanced level than that for landlines. If Mongolia has a developed mobile network infrastructure, it may be utilized in order to deliver educational materials on preventive care to far-flung reaches of the huge country to a people who until more recent times lived a nomadic herding lifestyle. This portion of the study was to be comprised primarily of preliminary web-based investigation conducted in Japan. Following this, interview surveys with integrated telecommunications services providers were to be conducted in Mongolia and educational materials that are suited to conditions in the country examined.

**Examination of delivery format.** Consideration was to be given to whether educational content should be distributed using physical media such as DVDs or via applications for smartphones or tablet devices based on the current state of communications in the country. The level of complexity of such an application was also to be determined, with questions asked as to whether selection or iteration of content is possible or whether learning progress could be recorded or not. In addition, the
method of delivery of the application was required to be decided upon (should it be web-based or to be downloaded?).

**Target Devices.** Based on the situation regarding adoption of devices among target users in Mongolia, types of mobile telephones, smartphones, tablets, PCs, etc., that may be used would be studied.

**Characteristics of Learning Resource.** As outlined in ‘Prototype Basic Plan’ below, consideration would be given to ‘Method of Presenting a Common Visual Message/Conveying a Strong Impression’ and ‘Importance of a Consistent Environment and Noise Reduction’ with the aim of realizing a synergistic effect using video and audio, relying as little as possible on representations using language. In addition, an attempt to effectively incorporate the points of view of regular third parties and parents (mothers) would be made.

**Evaluation of Learning Resource Prototype.** Evaluation at the trial level is to be carried out in Japan and a prototype created based on the results of these trials. This prototype will then be assessed in Mongolia and findings reflected in the final version.

**Schedule.** As shown in Figure 1, a survey plan will be drawn up between April and July 2016, and a basic survey conducted by early September. After this survey is completed, target devices and applications will be determined and from late September, a prototype will be created based on draft learning resource. The prototype will be evaluated in December, followed by localization. In February 2017, a representative from the National Center for Maternal and Child Health Mongolia will be invited to the Sapporo City University to take part in a technical workshop on handling and evaluation. Final evaluation will be completed by the end of the 2017 fiscal year.

**Preliminary Survey**

**Mobile Phone/Broadband Penetration Rates**

Figure 2 shows the number of mobile phone subscribers and mobile phone penetration rates in Mongolia based on figures found in the ITU World Telecommunication/ICT Indicators Database (WTID), 2014 (Ministry of Internal Affairs and Communications, 2016). The mobile phone penetration rate in 2013 was over 124%, indicating that each person owned at least one
When the research method was initially being considered, it was posited that the number of mobile phones would be greater than that for fixed phones. However, this high number of subscriptions was unexpected.

In contrast, Figure 3 shows broadband subscriptions and penetration rate based on the WTID. Compared to the number of mobile phone subscriptions, broadband adoption remains relatively low in Mongolia. Given this fact, sending huge amounts of data or downloading large files could be considered as problematic.

Internet Penetration Rate

Figure 4 uses ITU – ICT statistics (Sekai Keizai no Neta-cho, 2017) to compare Internet penetration rates in Japan and Mongolia. No data was collected in Mongolia between 2003-2006. As can be seen by this graph, the number of Internet users in Mongolia remains relatively low – another factor that may inhibit the exchange of large amounts of data or the downloading of big files.
Comprehensive Telecommunications Carriers

Table 1 outlines information based on the WTID on Mongolia’s four comprehensive telecommunications carriers. They are listed in order of year of establishment. As it was seen as difficult from a time-related perspective to visit Mongolia and study all four companies, a decision was made to focus only on the two companies with a combined almost 70% market share, companies ‘A’ and ‘C’.

Preliminary Survey Results
As shown above, the preliminary survey found that while the mobile phone penetration rate is extremely high, Internet usage and the broadband penetration rate remain low. In addition, it was determined that companies ‘A’ and ‘C’ would be the focus of further study. The survey was to include basic information such as broadband subscriber numbers, user plans, charges (by plan and class), applicable operating systems, OS penetration rates/usage figures, platform penetration rate, and popular applications as envisaged primarily in ‘Study on current state of ICT in Mongolia’ and ‘Examination of delivery format’. In addition, it would seek to obtain advice on methods of distribution, such as to whether it would be better to be provided online or as a downloadable offering and so forth.
Survey in Mongolia

Overview
It was necessary to obtain a concrete idea of the telecommunications environment in Mongolia; while it was known that, like Japan, Mongolia had four major telecommunications carriers and that the mobile phone penetration rate was 124%, only by visiting the country could a detailed picture be obtained. This process started by arranging meetings with the two carriers chosen after examining the findings as shown in ‘Comprehensive Telecommunications Carriers’ via email and telephone from Japan.

‘Company A’ Survey Overview

Findings. The director of the Public Relations/Government Relations Department was interviewed for the purposes of this study. The company has 1.3 million users and 19% of these are on post-paid plans that include data allowances of between 1-10GB/month.
Advice Received. Users rarely download files. It would be better for them to access information directly via a website or using SNS. In rural areas, the use of TV and printed pamphlets, etc., may be required. The suggestion of perhaps having the information incorporated into a health app, etc., was brought up.

‘Company C’ Survey Overview

Findings. The person interviewed was the person in charge of data and Internet services. Around half of the company’s 1.1 million subscribers use broadband. Prepaid data usage was previously between 200 and 500MB, but this has recently increased to 600MB-2GB. The basic charge for post-paid types buys between 200MB and 2GB, with around 2GB used per month on average.
Advice Received. Doubts were cast on the appeal of only distributing DDH-related resources. More interest may be generated if they were incorporated into a health-related app. Wi-Fi was not widely found in rural districts, and users are reluctant to download files. Web-based information rather than an app was recommended and SNS should be utilized.

Survey Results

In addition to the above findings, the details outlined below were also ascertained.

In terms of utilizing a stand-alone application, while the penetration rate for mobile phones is a sizeable 124%, many phones are pre-paid. Even for post-paid type phones, users use only around 2GB/month on average; they do not perform a lot of downloads. For these reasons, having users download a mobile application was not seen as appropriate.

In regards to usage or distribution via the Web/Internet, it was suggested that SNS platforms such as Facebook or Twitter may be more effective, as may including content as part of a healthcare-related mobile app. There was an opinion that more thought about the method of distribution was required and there was a realization that a simple roll-out was going to be difficult.
In addition to this, it turns out that there is a considerable disparity between Ulaanbaatar and rural districts. A 4G network exists in the capital, and 3G is available in the center of other urban areas in the country. However, outlying towns and villages only have 2G. The idea of utilizing TV or pamphlets and so on in rural areas was also brought up.

From these findings, the ICT-related situation considered in ‘Study Method’ showed that there is a disparity in terms of connectivity between cities like Ulaanbaatar and rural areas and that providing the learning resource via mobile application download, etc., would face difficulties. It was therefore decided to exclude the concept of supporting individual operating systems or devices from the scope of learning resource creation. The delivery of the resource according to the Internet environment in each region and training situation would be a challenge to tackle going forward.

In the course of conducting this survey in Mongolia, it was found that initial assumptions were not valid.

In addition to the creation of a video, it was decided that the learning resource prototype aim to take the form of a mobile application that can be used for self-study. Based on the above, the future direction of the study was to include the following:

- Creation of a DVD that can be played in a loop (for instance, in waiting rooms at hospitals).
- Based on the video, create a mobile application for smartphones and tablets for demonstration purposes.

After implementing the above in the current fiscal year, it was decided that the following be considered for roll-out from the following fiscal year:

- Deploy content on website.
- Consider creating stills for use via SNS.
- Tailor content for upload to YouTube.

**Video Shoot in Mongolia**

**Pre-shoot Practice Run**

As explained in further detail in ‘Prototype’ below, an action camera was procured in Japan to perform a practice preventive care video shoot from both a third-person perspective and a mother’s (first-person) perspective. As seen in Figure 5, this practice run enabled verification of camera positioning and where the action camera should be affixed, for instance. In addition, storyboards were created, enabling a review of task flow.
Location Shoot

The National Center for Maternal and Child Health Mongolia (hereinafter, the Center) was the location for the shoot. The Center gained the cooperation of parents of infants only a few days old, enabling the recording of the way newborns are held, breastfed, and so on using real babies. Figure 6 shows a video still from the action camera worn on the head of one of the nurses to how the view from a third-person perspective.

Following this, a nurse from the Center used a doll to demonstrate how to change a diaper and so on. As the nurse was most accustomed to handling newborns, the initially envisaged scenario could be recorded. The doll was chosen due to ethical considerations as the video also included demonstrations of dangerous (or prohibited) ways of handling babies (see Figure 13).
Prototype

Prototype Basic Plan

With the aim of developing a resource that would be able to cross language barriers, the following visual and auditory elements were considered:

Method of Presenting a Common Visual Message/Conveying a Strong Impression. The study focused on making effective use of the interaction between audio and visual elements in order to produce a common sensory quality (impression). For example, the impression of “brightness” is more strongly perceived when a “bright sound” is accompanied by a “bright color,” rather than when just the sound is produced by itself. This effect is called a synchronization of the senses. However, this synchronization does not only produce a feeling of “brightness” – a congruency between auditory and visual elements can also produce other types of impressions (Iwamiya, 1996).

Moreover, it was confirmed that the impressions observed across these types of multiple sensory modalities were limited not only to a Japanese language and cultural context, but could also be shared across the world in a variety of linguistic or cultural settings.

Importance of Consistent Environment and Noise Reduction. As a congruence could be deliberately created using visual and auditory stimuli that convey the desired message and in order to present a strong impression to viewers (Inao, Akita, & Koga, 2008), the points outlined below in particular were considered in the development of the learning resource. It was important to achieve a consistent environment and reduce noise, and frequent use of images for visual and auditory stimuli of a uniform nature was used to convey a strong impression.

In addition, the visual aspect was given particular attention for its role in self-study. Most teaching materials to now have used images shot from a third-person perspective. In order to ensure immediate and enhanced understanding, the learning resource prototype to be developed for demonstration purposes would also utilize images taken from a mother’s (first person) perspective to show actual mothers what they would see when looking at the baby. A storyboard (see Figure 9) was prepared in order to consider the overall flow and sub-content in the creation of the prototype for demonstration use.
Examples of Images Used in Prototype
Figure 10 shows a sample menu screen. While it uses text, it is quite simple in its design.

Figure 11 shows a sample illustration. This example explains that when breastfeeding or changing diapers, for example, the infant’s hip joint should resemble an ‘M’ shape, as it does when in the womb.
Figure 11. Sample illustration.

Figure 12 shows a sample image of the position an infant takes when nursing. Here, the main visual (video) shows the overall scene from a third-person’s perspective. Superimposed at the top left is another visual (video) showing the mother’s (first-person’s) view. Both visuals are linked in order for the viewer to see actions overall and see how these look from the mother’s point of view.

Evaluation/Findings

Evaluation of Prototype for Demonstration Use

Date/time: November 7, 2016 (Mon), 16:30-17:30
   December 14, 2016 (Wed), 17:00-18:00
Place: Sapporo City University School of Nursing (Soen Campus) Method: Check of video by 4-5 people involved
Outcome: It was decided that the following be addressed/changed:
   - Overall flow/length
   - Size of superimposed video
   - Positioning of incorrect position warning, etc.

These internal evaluation sessions helped to enhance the synergistic effect of the third-person and mother’s (first-person) views.

Figure 13 shows a still of an inappropriate action (prohibited action) using a doll. The viewer’s attention is called by use of an ‘X’ mark accompanied by a buzzer sound. As mentioned in ‘5.1.'
Location Shoot’ above, a lifelike doll was used in the filming due to ethical considerations.

*Figure 13. Example of an inappropriate action*

**2nd Evaluation Phase of Prototype for Demonstration Use by National Center for Maternal and Child Health Mongolia Staff Member**

- **Date/time:** March 6, 2017 (Mon), 16:30-17:30
- **Place:** Sapporo City University School of Nursing (Soen Campus)
- **Method:** Visitors from the National Center for Maternal and Child Health Mongolia looked over prototype and offered their opinions.
- **Outcome:** While the prototype was seen as being easy to understand, staff assessing it had specific points of feedback. For example, they felt uncomfortable about the action camera worn by the nurse in the scenes using an actual baby. They also reported that the spreading of the infant’s legs or the way in which its mouth was in close proximity to the nurse’s uniform was unnatural. This type of feedback was given close attention and would be used to make further improvements.

**Interim Conclusions**

The interim conclusions regarding the four study aims are as follows:

**Basic survey on the current state of communications in Mongolia.** The current state of communications, devices, usage and so on in Mongolia was ascertained through interviews with local integrated telecommunications services providers. This step yielded advice on what form the self-study resource should take and how it might be distributed.

**Trial of ‘DDH Preventive Care’ self-study resource aimed at parents.** Prototype video content that included new footage taken from both a third-person and first-person (mother’s) perspective was created based on learning material produced the previous year.

**Creation of prototype utilizing ICT.** A video/application production company has been tasked with creating a DVD video and a mobile application for demo use on iPhone/iPad platforms. This will allow for broadcasting on TV/playback in hospital waiting rooms, etc., in Mongolia,
and for demonstrations using iPhones/iPads.

**Conduct hearings and evaluation in the field regarding prototype.** The staff member from the Center who visited Japan in February 2017 gave positive feedback on the prototype content. On a subsequent visit in March 2017, staff members from the Center went through each scene and identified problem areas. This feedback will be used to make further improvements.

**Future Development**

The nurses from the Center who visited the Sapporo City University School of Nursing in early March for training offered feedback on the prototype content from the point of view of those who would be using it. Where possible, this feedback will be reflected in the resource during the current fiscal year, after which a DVD video and mobile application is to be made. If demand is present, the resource will be rolled out in the western provinces of Mongolia during the following year. The authors of this study hope that this educational resource will assist in lowering the incidence in DDH.

Abstract

Ideation flexibility is the ability to shift between a designer’s preferred and non-preferred ways of generating solutions as required by the presented task. There are many tools that exist to support ideation; however, there is a lack of research defining how to facilitate ideation flexibility and how to support designers in this process through use of such tools. In this paper, we report on the development of a new tool, the "Incremental to Radical Heuristics" (I2Rh), which may provide inspiring prompts for ideation, ranging from more incremental to more radical examples. We tested the use of this I2Rh with a small set of industrial design and architecture students and aim to report on ways in which designers with varying cognitive styles perceive and apply these heuristics and further the impact of the heuristics on the students’ problem solving processes and ideation outcomes. Preliminary results demonstrate that more innovative students found the adaptive applications of the heuristics to trigger more novel solutions, whereas the more adaptive students found that the innovative applications to be more inspiring.

Keywords: ideation tools, design heuristics, adaption-innovation theory

Ideation is critical as it allows designers to form many diverse ideas to choose from and eventually test and validate them (Sheppard, Macatangay et al. 2009). However, in many cases, designers find it difficult to come up with many diverse ideas as a result of fixation they experience on particular ideas (Crilly 2015). Being a flexible designer means being able to move from one solution to another, in order to produce the most promising solutions for the given context. In this movement, idea generation methods play a critical role as facilitators of this movement while pushing designers to think differently (Silk, Daly et al. 2014).

The focus of the proposed work is ideation flexibility (Yilmaz, Daly et al. 2014), defined as the ability to ideate in both incremental and radical ways – or, more precisely, to ideate along a continuum of thinking between the two, depending on the needs of the problem. Building on the theoretical foundation of Kirton’s adaption-innovation theory (Kirton 1976), we defined the ideation success as a designer’s ability to move between his/her preferred and non-preferred ways of generating ideas as required in the design brief. To specifically target ideation flexibility, we took an empirically-driven and validated ideation tool, Design
Heuristics (Yilmaz, Seifert et al. 2016), and modified it based on the Kirton’s adaptive-innovative theory. This revised set, called the "Incremental to Radical Heuristics" (I2Rh), illustrates heuristics’ application both incrementally and radically to the same example design problem. I2Rh is intended to help designers execute an ideation strategy based on prompts, examples, and directions to incorporate more incremental or more radical changes to their naturally preferred ways of generating ideas, through facilitating flexible thinking. Our goal in this paper was to investigate how designers with different cognitive styles perceive and apply these revised heuristics and their impact on the students’ ideation outcomes.

**Literature Review**

Adaption-Innovation Theory

Our work is grounded in Kirton’s Adaption-Innovation (A-I) Theory (Kirton 1976), which provides a robust framework for understanding and managing cognitive diversity in problem solving, with a particular emphasis on cognitive style. Cognitive style is an individual's preferred approach for solving problems and can be measured along a continuum from *adaptive* to *innovative*. While adaptors are more prone to improve the current system, innovators are critical of the current system, choosing to create entirely new products, processes, models, and solutions. As designers understand their own cognitive styles and their desired processes for problem solving, one may find the entire design process to progress much smoother and more productively. Further, it is important to note the relationship between one's preferred style and actual applied behavior. Actual behavior, employed towards a design task, is a combination of preferred style and learned coping behavior. If one possesses a more adaptive style, while called upon to perform tasks that have few guidelines or established structures, he or she will tend to resort towards coping behavior, often leading to stress in the long-term. The converse is also true of those of the more innovative style.

Design Heuristics

Design Heuristics is an evidence-based idea generation tool and was developed to help designers think systematically and in a diverse manner throughout their idea generation process (Yilmaz, Seifert et al. 2016). This tool captures cognitive “rules of thumb” used by designers to intentionally vary their series of prospective designs, and was gathered via data collection from protocol studies of designers and engineers talking aloud during ideation, analyses of award winning products, and a case study of a long-term design project. The resulting set of Design Heuristics capture seventy-seven different strategies, each of which can be applied independently or in conjunction to create new designs. Each card displays a different strategy (Figure 1), supported with product examples showing their application.
Development of the Incremental to Radical Heuristics (I2Rh)

Using the prior Design Heuristics tool and the A-I Theory, as its foundation we created a modified version of the tool, called the "Incremental to Radical Heuristic (I2Rh) Cards."

This revised set illustrates heuristics’ application to a design problem from both an incremental and radical, such that both ends of the A-I spectrum are presented, allowing designers link the heuristic with a real-world application.

We started with the original list of heuristics as a basis. We aimed to replace the product examples on the back of the cards with new examples, showing how each heuristic can be used adaptively and innovatively. Award winning products were collected from a variety of sources to create a database to choose the appropriate ones from. Once the product example was determined to fit that heuristic, a problem statement was reverse-engineered for further exploration. Unlike the product examples which align with the heuristics, this problem statement was independent, such that those using the tool may situate the example products in a relatable design problem framework. All problem statements on the cards were phrased, starting with “Design a way to…” and then expressed a constraint from which to design around. Finally, for each card, an additional product example was selected, which fit the heuristic, problem statement, and was either more incremental or radical than its counterpart example.

For example, on Heuristic 39, the front of the card (Figure 2a) presents a synopsis of what it means to incorporate the environment when applied to product design. Using basic geometry and minimal details, the approach is placed the idea into context in an explanatory fashion. On the back of the card (Figure 2b), the orange-framed shape presents the problem statement while the incremental and radical product examples responding to this problem statement are display below, followed by descriptions of the products and why they are either radical or incremental applications of the heuristic. For coding the prototypes, each product example either has a pink (left, incremental) or blue bar (right, radical) to indicate which approach is the incremental or radical example as applied to the problem statement.
Research Methods

Our study was guided by the following research questions:

1. How do design students perceive and use the I2R\textit{h}?
2. How do high adaptors versus high innovators use the I2R\textit{h}?
3. How do the adaptive versus innovative product examples impact solution outcomes?

To answer these questions, we conducted an exploratory study where participants were introduced to this new tool and asked to generate solutions to one of the two problem contexts provided. Participants were industrial design and architecture students at a large mid-western university. The study was held during a university sketch club event. In total, 26 students participated in the study, 3 freshmen, 14 sophomores, 2 juniors and 7 seniors. The group was 17 male (65%), 9 female (35%), ages between 18 and 26.

Each student was provided a study package that had informed consent forms, Kirton Adaption- Innovation Inventory (KAI) to assess cognitive styles, problem statements, two reflection surveys, a post-ideation session survey, a demographic survey, and ten blank ideation sheets (five per ideation session). The design problems have been shown to be accessible by students with diverse cognitive styles and were neutrally-framed (Silk, Daly et al. 2014) to lead participants to generate ideas in their preferred manner. Each student was given only one problem for their session.

Data Collection and Analysis
Figure 3 depicts the steps taken for this experimental study. Students were asked to fill out the KAI. Next, students were given one of the two problems (Table 1) and asked to generate solutions without the tool, for twenty minutes. This was followed by the reflection survey.
After this initial, neutral ideation session, students were introduced to I2Rh, and were provided a small subset of the cards (10). Students, then, once again, were asked to generate solutions for the same problem they used for the first ideation session in twenty minutes; however, this time, with the I2Rh tool. Participants were prompted to use the I2Rh to either build off their previous concepts or create totally new concepts. They were free to select either the adaptive or the innovative example presented on the back of the cards to inspire their ideas. On the ideation sheets, they were then asked to report on the heuristic and the product example they used to initiate their concepts, using the color coordination. Though, participants were not told which color was associated with incremental or radical to avoid swaying their preference. Following this session, participants completed a second reflection survey. In total, students were given twenty minutes for the two ideation sessions and ten minutes for the reflection surveys. Finally, participants concluded the study by completing a post-ideation session survey, asking questions on the ease of use and the effectiveness of the tool, and their demographics.

Our preliminary analysis focused on the overall use of I2Rh, as well investigating the ‘extreme’ cases (high adaptors versus high innovators), comparatively. We identified high adaptors as participants with KAI scores lower than 78, and high innovators as participants with KAI scores higher than 112, based on Kirton's hypothesized mean of $\mu = 95$, plus/minus one standard deviation ($\sigma = 17$). We compared the students’ ideation outcomes achieved using the I2Rh with the outcomes they generated during the neutral ideation session, all relative to their KAI scores, to determine whether and to what degree the I2Rh facilitated a shift in the students’ ideation to be more adaptive or more innovative.

**Discussion**

In this paper, we report on the results of 25 participants, as one participant was removed from the data due to not completing the second ideation session. A histogram of the KAI cognitive style distribution for the 25 students is provided in Figure 4. It is interesting to note the slightly more innovative mean for our sample (96.64), when compared with the general population (95).
25 students generated 109 concepts in the Neutral ideation session (M=4.16; SD=0.89) and 88 concepts in the I2Rh ideation session (M=3.52; SD=1.12). A paired-samples t-test showed significant difference in the concepts generated for the Neutral condition (M=4.16; SD=0.89) and the I2Rh condition (M=3.52; SD=1.12) conditions; t(24)=3.720, p =0.001. This drop in the number of concepts generated may suggest that the students needed more time to read, reflect and apply the I2Rh cards, as the time for both sessions were 20 minutes, each. This may also partially be due to fatigue as the Neutral condition was given first to all participants. Although there is a decrease in the number of concepts in the second session, students continued generating concepts for the same design problem. When compared the two problem context, there is no significant difference in the number of solutions generated (both 96).

22 participants out of 25, reported use of the I2Rh, while 3 participants (KAI:s: 84, 124 and 130) did not claim the use of either example in generating solutions. Instead, they used the heuristic as a prompt:

P2: “While I didn’t always follow the prompt on the card it gave me a solid jumping off point.”

P4: “Instead of imagining scenarios/problem, I was creating them trying to make the card work instead of looking at the problem already there.”

21 participants (out of the 22 who claimed I2Rh use) used the adaptive example while 17 people used the innovative example, as prompts to diverge from preferred ideation approach. This difference might be due to the fact that the adaptive examples were the first example students saw. This is consistent with the use of the innovative example versus the adaptive example to generate the very first concept. 15 participants used the adaptive example first whereas only 5 participants used the innovative example to assist generating the first concept. 16 participants used both examples, whereas 5 participants used only the adaptive examples (varying KAI:s between 88 and 113), and 1 participant used only the innovative example (KAI=64). In this pool, only 2 participants claimed that they used both examples to generate a solution.
Figure 5 demonstrates how a high innovator used the incremental product example and how high adaptor used the radical example on the same heuristic card. The incremental example (the left) on the card shows a speaker that gives opportunity to the user to twist it in one way, in order to attach it on a bag or a bike. The radical example (the right) extends the flexibility in unexpected ways through suggesting the speaker be wrapped around anything.

For the snow transporter problem, Participant 5 (KAI= 120), using the incremental example, designed a sled with an auger mechanism on the bottom to propel the user over the snow. They seemed to use the incremental example in a more literal way, similar to a helix, and connected that to a common form for propulsion, the Archimedean screw turbine. They applied the twist to the mechanics, to describe how the product would function. On the other hand, Participant 6 (KAI= 69) used twist to apply flexibility and dynamic properties to skis so they may transform into snowshoes. This idea exemplifies the prime connection adaptors have with radical examples. They combined two products which already exist, skis and snowshoes, through using the flexibility feature given in the example. Even if this is only one case, we can see how an incremental way of applying the heuristic led the designer to think about elaboration on existing concepts, versus how radical use of the heuristic led the designer to explore new solutions through connections provided by the principle.
The I2Rh cards worked in different ways with adaptors and innovators. Adaptors sometimes had a difficult time connecting the card to their ideas because they would become fixated on the product examples being something they “had already thought of” in the neutral session. Other remarks from adaptors were related to speed. They felt the need to read and understand the entire card which greatly slowed down their ideation process. Innovators said the cards helped them to generate more radical ideas, but felt it took longer to understand the problem. They had a hard time relating I2Rh to their given problem prompt and they took the focus from creating solutions for a problem to feeling they need to make the heuristics fit the problem.

We saw a greater number of participants using the cards as inspiration for their previous ideas as opposed to using the product example in its literal form to be incorporated. Sometimes the cards caused unnecessary confusion in the participant due to the amount of information on each side. CO-P8 claimed the product examples didn’t relate well enough to the I2Rh cards’ title causing creating unwarranted confusion for the participant to apply the card towards their own ideation. Conversely, many people found the cards to act as an aid to their ideation process rather than a hindrance.

**Extreme Cases: High Innovators versus High Adaptors**

Within this particular sample of 25, there were 6 "extreme" participants (Table 2). High innovators demonstrated KAI scores greater than 112, while high adapters possessed KAI scores less than 78. The four high innovators (KAI 113-130), used four incremental cards with only one radical card. Conversely, the high adapters, two incremental cards versus six radical cards were used. This difference, although within a small subset of participants, appears to show that the students on the extreme sides of the cognitive style continuum preferred using examples that were on the opposite side of their preferred ideation approach.

**Conclusions**

Capability to ideate both incrementally and radically, based on the problem context and the requirements, and the awareness to move on this continuum is critical for designers. In order to help designers in navigating the solution space both incrementally and adaptively, we developed a tool, called, I2Rh. We found that high innovators tend to favor the incremental examples and high adaptors favor the radical examples. We also saw evidence of how radical use of the heuristics led to building new connections to create a new concept whereas
incremental use pushed the designer to consider identifying mechanisms and further details. Although this paper’s focus was not the investigating the impacts on concept sketches, it is apparent that the examples on the cards often led to very literal and directly inspired ideas. This may speak to a potentially detrimental effect of the tool's use, as often allowing the mind to naturally wander can be incredibly rewarding for designers. Alternatively, the tool may sometimes feel forced, rather than act like an aid for designers. During the neutral session, participants thought their ideas were very creative and they were comfortable with their personal ideation processes. That said, the cards may have demonstrated their value for once a designer has exhausted his or her ideas, is stifled by a creative block, the cards may assist in producing a larger pool of ideas to spark a new direction to pursue or suggest a way to manipulate earlier ideas.

Abstract

In the past decades, universities’ involvement in socio-economic development, which goes along with their teaching and researching activities, has defined a new role for them in society’s ecosystem. This new role is often referred with the term of “entrepreneurial” university, whose objectives are positive societal, economic and environmental impacts. In order to fulfil such objectives, entrepreneurial universities might engage in cross-sector collaborations with external organisations. Despite the great contributions that cross-sector collaboration can give to the partners involved, the outcome is mostly unfocussed and rarely embedded. This paper explores the outcome embedding in the cross-sector collaboration between entrepreneurial universities and the private sector. To this end, we provide the case of the collaboration between a Dutch airline company and four Dutch entrepreneurial research and teaching institutions. We aim to uncover hindering and enabling factors to the outcome embedding in order to design an interaction platform, design it together. This platform will be a tool to encourage the outcome embedding, moving from being inspired by to the actual implementation of the cross-sector collaboration. In order to fulfil this goal, this study employs a research through design methodology. This approach is a generative process, where cyclic loops of iterations and evaluations with stakeholders tend to the research goal. The solution is a digital platform, co-created with all stakeholders. This study can inspire practitioners and future research on the problem of unsuccessful cross-sector collaborations, between entrepreneurial universities and external organisations, with more emphasis on the value of embedding and translating the outcomes.

Keywords: Innovation; Outcome embedding; Research through design; Boundary experiences; Cross-sector collaboration.

In a knowledge-based society with increasing societal and economical needs, universities can assume a different role (Safiullin, Fatkhiev & Grigorian, 2014). Etzkowitz & Leydesdorff (2000) call this new type of university “entrepreneurial”, where the involvement of socio-economic development is as important as their teaching and researching activities. These new type of university does not only represent a knowledge tank for external organisations, but it also takes an active role as an actor of change. The entrepreneurial university wants to be part of the change, developing solutions based on in depth scientific studies (Safiullin & al., 2014). Hence, these types of research and teaching institutions seek for external collaborations to acquire new skills and prototype
new solutions that might have positive social, economic and environmental impacts. In a more complex society, where a sole stakeholder can hardly solve contemporary challenges, the cross-interaction with different domains and expertise is often suggested, if not extremely needed (Rondinelli & London, 2003).

According to Chesbrough, Vanhaverbeke, & West (2006), cross-sector collaboration cherish the formation of novelties, bringing innovative contributions to all parties involved. However, a cross-sector collaboration often lacks common objectives, trust and appropriate strategies, leading to unsuccessful alliances (Bryson, Crosby, & Middleton Stone, 2006; Jamali & Keshishian, 2008), where the outcome is mostly unfocussed and rarely embedded (Pavitt, 2001; Laursen & Salter, 2004). This paper explores the collaboration between four Dutch entrepreneurial universities and teaching institutions, mainly focused on design and aviation, with a Dutch airline company. In this context, the challenges of cross-sector collaboration are amplified by the fact that design professionals have a more intuition-based approach towards problem solving, whereas business professional tend to have a much more rational approach (Calabretta & al., 2016). This might cause frictions and tensions between the twos, which could lead to difficulties in the implementation and embedding of the collaboration outcomes. The goal of this research is to uncover factors that hinder as well as enable this cross-sector collaboration, with an emphasis on the outcome embedding. Once these factors are detected, we aim to design a cross-sector boundary experience (Feldman, Khademian, Ingram, & Schneider (2006), namely the interaction platform, which could shift the collaboration’s focus from mainly adding on each other’ knowledge and expertise to the prototype and embedding of the common outcome.

According to Feldman & al. (2006), cross-sector boundary experiences are shared or joint activities that create a sense of community, enhancing the ability to overcome stakeholders’ boundaries. In order to succeed, cross-sector boundary experiences need to take place within a cross-sector boundary group, with the aid of cross-sector boundary objects (Carlile, 2004). The cross-sector boundary group examined is the one created by the collaboration of the entrepreneurial universities and the airline company. Design professionals often use visualisations and rapid prototypes as cross-sector boundary objects, to transcend boundaries among stakeholders (Calabretta & al., 2016). Hence, our contributions to the entrepreneurial university and industry collaboration literature is to make use of the cross-sector boundary experiences, groups and objects, with an emphasis on the last ones. We believe that, by employing visualisations and prototypes in the creation of the interaction platform, the outcome embedding will be more luckily to happen (Calabretta & al., 2016).

**Literature Review**

In the following section, we introduce the three main research domains on which this study is grounded. First, we discuss the cross-sector collaborative innovation, highlighting the actions, behaviours and leadership undertaken. Second, we investigate the literature referring to the new role of the entrepreneurial university. Finally, we discuss the literature referring to the tensions created and the outcome embedding when multiple stakeholders co-design.

**Cross sector Collaborative Innovation**
Despite the great contribution that cross-sector collaborations have in cherishing novelties (Chesbrough & al., 2006), they often lack common objectives, trust and appropriate strategies, leading to unsuccessful alliances (Bryson & al., 2006; Jamali & Keshishian, 2008). An unsuccessful cross-sector collaboration is characterised by unfocused and rarely embedded outcomes (Pavitt, 2001; Laursen & Salter, 2004). Failure or success depend on many factors, such as behaviours, actions, trust and available resources (Jamali & Keshishian, 2008). In addition, the type of leadership undertaken by the partners also affect the cross-sector collaboration’s success (Bryson & al., 2006; Crosby & Bryson, 2010). A successful cross-sector collaboration does not only work on an institutional level but it also enhance collaborative behaving between individuals. According to Buerkel (2013) and Kanter (1994), personal commitment and individual curiosity are important drivers for successful cross-sector collaboration as much as active and proactive roles taken on an institutional level (Dahlander & Piezunka, 2013).

If collaborative behaviours, personal commitment and individual curiosity must be encouraged, determinate actions must be taken on an institutional level to maximise the external contributions (Dahlander & Piezunka, 2013). The authors make a distinction between proactive and reactive attentions. The former refers to the idea of submitting internally developed ideas to the external partners. The latter to the one of responding actively to the external stimuli in order to show interest. However, employing people with a strong curiosity or a strong result-driven personality (Kanter, 1994) and engaging in proactive and reactive attention is not enough. A shared agreement and multiple decision makers often characterise a cross-sector collaboration (Bryson & al., 2006; Crosby & Bryson, 2010). Hence, the type of leadership role undertaken by the partners could have a strategic relevance for the success of cross-sector collaborations. Bryson & al. (2006) and Crosby & Bryson (2010) believe that the cross-sector collaboration leadership should be built in a regime of legitimacy and sharing, where a shared purpose is created through formal and informal decision making processes (Samii & al., 2002). This type of leadership is named “integrative”, which means gathering different groups, each with a different level of expertise and domains, in semi-permanent ways (Crosby & al., 2010). This leadership manage a collection of actors drawn together because of their complementary resources and capabilities defined as a cross-sector boundary group (Feldman & al., 2006). This collection of actors run to co-create and co-produce cross-boundary experiences, building on each other’s knowledge gaps. The cross-sector boundary experiences are facilitated by the use of boundary objects and tools (Carlile, 2004), designed for translating the different organizational languages and beliefs into sharable knowledge within the stakeholders.

To conclude, we have seen how cross-sector collaborations can be influenced by three main elements. Firstly, the curiosity, engagement and creativity of individuals. Secondly, the activities undertaken on an institutional level, both proactive and reactive ones. Thirdly, the type of leadership, an integrative one, that could manage the creation of cross-sector boundary groups, sustained with cross-sector boundary experiences and tools that would break through stakeholders’ barriers. The elements highlighted in this literature review were useful to focus this research on the interplay between the individual factors, such as curiosity and engagement, and the institutional ones, namely the reactive and proactive approaches undertaken by an integrative leadership. This interaction can happen in the creation of cross-sector boundary groups, experiences and objects, determining a cross-sector collaboration towards the outcome embedding. In the next paragraph, we will discuss the characteristics and the role assumed by the entrepreneurial universities in the
Entrepreneurial University

Academia and corporate environment are interacting more and more, creating an ecosystem made of multiple stakeholders where new researches, spin-off and start-ups come to life (Leydesdorff & Etzkowitz, 2001). This type of interaction is a strong synergetic collaboration, at the antipodes with the past decades where the actors only contributed according to their competences, delivering a product and not co-producing the outcome (Leydesdorff & Etzkowitz, 2001). In the new interaction between university and industry, the inter-space determinates new hybrid organizations, where the different stakeholders collaborate and work together.

Safiullin, Fatkhiev & Grigorian (2014) has explored both advantages and disadvantages of the “entrepreneurial university”. Some of the most interesting disadvantage is that university-industry interaction is rather a way to show each other interest than a way to produce a tangible product. Furthermore, each institutions might lose their ability to innovate independently. On the other side, advantages for universities lay in a larger access to market, by increasing its possibility to produce scalable products together with the industry.

To conclude, the entrepreneurial university forms students that are capable of becoming entrepreneurs and firm founders, where the involvement in socio-economic development is critical and the inclination towards cross-sector collaboration is strongly accentuated. Rather than only serving the industry as a source of inspiration and technological generation transfer, entrepreneurial universities can build cross-sector boundary groups together with corporates and industries, where new firms, start-ups and innovative and disruptive innovation happen (Leydesdorff & Etzkowitz, 2001). However, as it was already mentioned, the interaction between entrepreneurial design-driven university and industry can generate frictions that are due to the more intuition-based and research approach of the former and the more analytical and business oriented approach of the latter (Calabretta et al., 2016). In the following paragraph, we investigate these tensions to understand how to overcome them towards the outcome embedding.

Outcome Embedding between Design & Business Professionals

Designers often find it difficult to break through the company’s barriers to implement and embed design outcomes, leaving the client with great innovative and inspirational concepts yet not likely to be implemented (Calabretta, Gemser & Karper, 2016). According to Calabretta et al., (2016), innovation lays in the interplay between intuition and rationality, the so-called paradoxical tension. The paradoxical tension is not investigated deeply in this research, but it is worth referring to the author’s’ work, where a special place is occupied by co-creation techniques and design tools (such as visualization, prototyping etc.). Those are useful to translate the design language into outcomes that are easily accessible and understandable by all stakeholders involved, making the outcomes shareable across stakeholders’ cultural boundaries (Buerkler, 2013; Calabretta & al., 2016). The role assumed by co-creation techniques and design tools can be compared to the one of cross-sector boundary groups, experiences and tools (Carlile, 2004, Feldman & al., 2006; Bryson & al., 2006).

In addition, prototypes and visualization elicit emotional commitment, rising up the
feeling of ownership, which is fundamental to embed the design outcome (Calabretta & al., 2016) also in cross-sector collaborations.

Murphy, Perrot & Rivera-Santos (2011) investigated the role that co-designing has on cross-sector collaboration outcomes. The authors claim that piloting the potential co-designed solution on a small scale can improve the chances of implementation and embedding, overcoming the gap between different knowledge and cognitive structures. In addition, the same authors affirm that designing processes and routines for cross-sector collaboration purposes can steer the focus of the company’s’ attention to the benefits of collaborating, facilitating the process towards embedding and implementation.

In the literature review, we first focussed on the role assumed by cross-sector boundary groups, as means to merge creative and enthusiastic individuals with reactive, proactive and integrative institutions. Then we illustrated how frictions and tensions exist between the entrepreneurial universities and their partners, focussing on the advantages and disadvantages as well as on the two different approaches towards problem solving. Finally, we presented how the same tensions arise between design professionals and business professionals, showing how the twos embrace their diversity to overcome barriers and create innovative solutions thanks to co-designing, co-piloting, visualisations, and rapid-prototyping. This analysis gives a different perspective on the variables that influence the outcome embedding, both as a success and as a failure, in the cross-sector collaboration between entrepreneurial universities and the private sector.

**Methodology**

In line with the exploratory objectives of this study - which include building a tangible solution and knowledge simultaneously -, this research employs a research through design methodology (Zimmerman & Forlizzi, 2008; Sanders & Stappers, 2012). This approach is a generative process, where cyclic loops of iterations and evaluations with stakeholders tend to the design and research objective (Stappers, 2007). The methodology employed was divided into two phases, each with specific aims and tools. The first phase aimed to produce knowledge around the factors that enable and hinder the cross-sector collaboration outcome embedding. To this end, 21 interviews were carried out, of about 30 to 40 minutes, with an informal conversational approach and audio recording (Patton, 2002). The panel of participants is chosen from the Dutch airline company departments and the four Dutch research and teaching institution. The selection criterion for the airline company participants was to have collaborated on research/design projects with at least one of the four institutions examined, 11 respondents were selected in total. The same criterion was adopted for the respondents from the research and teaching institutions, where 10 respondents were selected in total. The interviews were designed in three main sections. The first one aimed to uncover the positive and negative aspects of a cross-sector collaboration, in order to understand the stakeholders’ motivations. In the second part, we focussed on the selection procedure of the right candidate, expertise and knowledge shared in the collaboration. The last part aimed to uncover the type of outcome of the cross-sector collaboration, both actual and desired. The structure of the interview followed a hypothetical collaboration structure: initiating (reasons), conducting (selection of people, knowledge and resources sharing) and finishing (desired and actual outcome). The second phase of the research aimed to set design features to be part of the interaction platform. To this end, a co-creation session took place at the Digital Studio of the airline
company. The co-creation session was recorded and video recorded, and design stimuli were used to generate creative inputs (Stappers, 2007; Sanders & al., 2012). The co-creation involved the airline company’s employees and researchers from the Dutch research and teaching institutions selected. The selection criterion for the participants was the same adopted for the interviews carried out initially. Nine participants, divided into 2 groups, joined the session that lasted for about 2.5 hours. The two groups were formed in order to have an equal representation of the airline company’s employees and the researchers from the institutions selected. The co-creation aimed to set design features by uncovering the drivers and key performance indicators (KPIs) useful to align stakeholders’ aims with customer/user satisfaction (Calabretta & al., 2016). Each group carried out two exercises separately, followed by an open discussion and presentation of each group’s work. The tool employed for the first part of the co-creation was a motivation matrix (see figure 2a, 2b). This tool investigates current and future expectations for the design that is under examination (Jégou, Manzini, Meroni, 2005; Morelli, 2007).

![Figure 1a Motivation Matrix, group A](image)
The second tool employed was the service flow & KPIs (see figure 3a), a design tool based on the service blueprint, which is a tool employed to manage and maintain a service (Bitner, Ostrom, & Morgan, 2007; Morelli, 2007). The design features were drawn by connecting the drivers (motivations), as result of the motivation matrix exercise, to the KPIs, uncovered with the service flow & KPIs exercise.
Figure 3a. Service Flow & KPIs, group A
The data gathered from the interviews and workshops were coded and clustered following multiple steps (Eisenhardt, 1989; Miles & Huberman, 1994). The materials gathered during the co-creation session included audio and video recordings, tools used and pictures taken during the session. The analysis consisted of listening and writing down the main elements (Patton, 2002). The “analysis on the wall” was employed to analyse the materials gathered, which provided both inspirations and information (Stappers & al., 2007). The data were clustered into three design features categories: People, Activities and Structures.

Findings

In this section, the results from the interviews and the co-creation session are presented. First, the factors that enable and hinder the cross-sector collaboration, drawn from the interview analysis, are briefly explained. Second, the design features of the interaction
platform are presented, as result of the data gathered during the co-creation session. Finally, the concept design of the interaction platform is illustrated.

**Enabling & Hindering Factors for the Outcome Embedding**

The enabling factors are the ones identified as responsible for the outcome embedding in the cross-sector collaboration between the Dutch Airline company and the four Dutch teaching and researching institutions. These factors are clustered in three categories, *connecting research & researchers; prototype & results as inspirational tools; behaviours learnings* (figure 3). On the other hand, the hindering factor are the ones that represent a large barrier to the outcome embedding in the cross-sector collaboration. These are clustered in three categories, *lack of structure, low commitment & enthusiasm, closed innovation* (figure 3).

Figure 3. Enabling & Hindering Factors

**Enabling Factors**

**Connecting Research & Researchers:** This makes sure that the current researchers are tuned to the past and future ones, using the knowledge already produce to design innovative products and vice versa. (“*We already collaborated with ***, but I wish we could have a place where all the different universities and *** can come together with companies, also from different sectors, and co-design. Respondent I*”)

**Prototype & Results as Inspirational Tools:** The strength of students lay on their ability of inspiring the stakeholders, triggering new challenges and arising new questions in the corporate culture. Prototypes are important to make the outcome tangible and sharable, therefore more luckily to be understood and embedded. (“*Companies recognize the huge potential for use design to enhance products / breakthrough innovation etc. as a student you can show that your design is impactful visually and physically by making things*”
Respondent M)
Behaviours Learning: Personal interactions are fundamental for the success of cross-sector collaborations; trust, empathy, emotions, are often enhanced by a day-to-day working practice. Students can learn from employees and vice versa. (“Working with students, it stimulates your own staff to think differently, to use different methods and to bring new insights. Students do not externalise the problem, they interiorise it” Respondent J)

Hindering Factors

Lack of Structure The current situation makes the communication between stakeholders arduous and slow. The decision-making process is often depending on the chance (“There must be a click with the professor, it is a matter of coincidence or chance, there is no clear structure and therefore there is no cross communication intra and inter faculties. Respondent H)

Low Commitment & Enthusiasm: A low level of commitment and enthusiasm is recorded during the collaboration. This is due to time-consuming activities, loss of communication and misunderstanding of the design/research directions. (“Sometimes they have the feeling that is a “small student project” that they do not really care. It depends if the projects are likely to be valuable for them or not” Respondent T)

Closed Innovation: Innovations are often close innovations, hindering the knowledge flow between the stakeholders. This causes barriers between the different entrepreneurial universities working with the same partner, damaging all. (“I say open up the findings and the researches. They are too much focused on the short end value. They ask us to become partners not like signers (I do not want to ask my students to develop only a dashboard, we want to be open to innovation, and this is an university, you know”. Respondent G)

Design Features for the Interaction Platform.

The result of the co-creation analysis brought us to define the design features for the interaction platform. These are clustered in three main categories: People, Activities and Structures. The design features are drawn by connecting the drivers, identified with the motivation matrix, to the key performance indicators, uncovered with the service flow & KPIs tool. In fact, by connecting the goals and aims (KPIs) to the motivations and triggers (drivers) it is possible to design design features which are more luckily to enable the outcome embedding. Below, we briefly illustrate each category and indicate the main components.

People

People category refers to different tools that enable the connection and the communication throughout all the stakeholders involved, encouraging the outcome embedding. There are three main components: Student Profile, Network Alumni, Open KPIs and Research Clusters. The first one, the Student Profile (drivers: collaboration cross borders, new perspectives, not airline biased – KPIs: selecting the right students into the right projects) aims to connect the researches to the people that are actually carrying them on. The Network Alumni, (drivers: Learn across domains and access & connect to other researches – KPIs: Training talented students, high level of projects, high number of students) creates and ecosystem of entrepreneurial students working together. The last two components,
**open KPIs and Research Clusters**, are a way to first create an open-end environment, second to generate new knowledge based on the ones already produced (drivers: *Learn across domains and access and connect to other researches / departments; finding the uniqueness and the singularity of each - KPIs: Collect data, connect with other researches and businesses, build on each’ others work, shared facilities*).

### Activities

The activities category refers to the set of tools that could enable the actors to move from only being connected and aligned to the actual making and doing of the cross-sector collaboration. It has three main components: Finding a sponsor, Design a Sprint, Special Lectures & Events. The first one, *Finding a Sponsor* (drivers: Get research funded – KPIs: Finding partners and support for researches) aims to give a tool for researchers to find sponsors, as well as to private partners to find project to sustain. The second one, *Design a Sprint* engages stakeholders to be active player of the collaboration, by organising workshops, rapid prototyping and co-creations (driver: *Experiment and simulations via the (airline company) facilities – KPIs: Placing existing innovation, experiment with technologies*). Finally, *Special Lecture & Events* component is a way to share facilities and knowledge with more emphasis on the face-to-face interaction (drivers: *top-down interest and interaction with managers - KPIs: Incorporate talents, provide access to the creative industries, proactive involvement, media attention*).

### Structures

This last category is meant to bring a set of structures and tools to organise the cross-sector collaboration. *Report ideas, Recorded Diary, and Tools Ready to Use* fall into this category. Whereas the first twos are a way to keep the stakeholders’ updated and to give them the space to drop ideas, the last one is the most interesting for this study. As we already mentioned earlier, in this research we focussed on the role of co-creation techniques, rapid prototyping and visualisations in the outcome embedding of the cross-sector collaboration. Hence, this component is extremely relevant, because it elicits the shift from *thinking* to *doing* thanks to the help of tools (drivers: *train employees, gain new perspectives, learn across different domains – KPIs: employees and students satisfaction, engagement and learning*).

### Design It Together: A Cross-sector Collaboration between Entrepreneurial Universities and a Private Partner.

The enabling and hindering factors presented earlier, together with the *design features*, set the foundation for the design of the cross-sector collaboration. The *design it together* platform is inspired by the already existing platforms that engage people all over the world, with different domains and expertise, to co-design and co-create. Ill, Brown & Davison (2010) recognise the value of the DIT, do it together platform, as they pull a large number of individuals and talents to innovate and increase performances on an ongoing basis. A do it together platform between the entrepreneurial universities and private partners will create a space for students, researchers and employees to co-design, co-create and share their results. The private partner can make use of the institutions’ unique selling points, whereas the entrepreneurial universities can find funding for their research, contributing to have positive social, economic and environmental impacts.
The design it together platform addresses the challenges highlighted in this research by means of three main contributions. These three main clusters are also reflected in the design of the platform divided in three main sections: Research, Doing, Who We Are. First, the Research (see figure 4) section enables connection of research and researchers, thanks to the design features such as research clusters and open KPIs, giving an overview and overcoming the lack of structures reported by the respondents. Second, the Doing section enables the stakeholders to make use of tools like prototypes, reports and visualisations as inspirations but also as means to create innovation (see figure 6). In addition, the design features Tools and Design a Sprint, by engaging multiple stakeholders and sharing contents, open up the innovation transcending institutional barriers. Third, the Who We Are section illustrates clearly the objectives and goals of the partners who engaged in the collaboration (see figure 5).

Figure 4. Research Clusters
This makes the collaboration trustworthy, setting the focus on the outcomes as well as being clear on the strategy taken. In addition, by showing the students profile (design feature such as videos and pictures of the project) on this section, as well as the profile of each partner, the platform encourage empathy and commitment, connecting the researches not only to abstract facts & figures but also to people that made it possible (see figure 7).
Discussion and Conclusions

In this paper, we discussed how the outcome embedding is extremely relevant in the cross-sector collaboration between entrepreneurial universities and private partners. To this end, we investigated the case of the collaboration between four Dutch entrepreneurial research and teaching institutions and a Dutch airline company. In order to uncover enabling and hindering factors to the outcome embedding, so to design an interaction platform for the stakeholders considered, 21 interviews and a co-creation session were carried out. From the analysis of these, we clustered three enabling factors and three hindering factors, together with three categories of design features to use as foundation for the design of the platform. The result is a structured cross-sector collaboration, where information, knowledge and outcomes are shareable between the stakeholders. This is presented as a friendly and open digital space, which has a strong connotation on tools, people and activities regarding the cross-sector collaboration.

The potential of this study is to be found in the accentuated interest in the outcome embedding of the cross-sector collaboration between the entrepreneurial universities and the private sector. We argued that the outcome embedding is a strong incentive for stakeholders to engage in a cross-sector collaboration, because the stakeholders, transcending their cultural boundaries, can have tangible and visible results through an embedded outcome (Calabretta et al., 2016). This is particularly true if they are co-created and a sense of commitment and enthusiasm is elicited. Furthermore, the contribution of this study is to be considered also in the application of the design methods to overcome the obstacles of the outcome embedding, between the design professionals and the business ones, to the entrepreneurial universities and the private partners’ interaction. In fact, we discussed how co-creation techniques, co-design, visualisation and rapid prototyping can function as cross-sector boundary objects (Carliile, 2004; Feldman & al., 2006, Corsby & al., 2010) in the cross-sector boundary group formed by entrepreneurial universities and private partners. A new category was introduced in the entrepreneurial university-industry outcome embedding: inspiring through prototypes and visualisations.
Although this study can serve as a first attempt to apply design techniques towards the outcome embedding for cross-sector collaboration, with a focus on the entrepreneurial university-private partner’s interaction, some limitations are to be considered. First, this study was carried out with entrepreneurial researching and teaching institutions that are active in the field of design thinking and design doing. A future study should consider another pool of entrepreneurial universities and undertake the same approach to compare the results. Second, a user test and another co-creation session should have been carried out to double validate the results obtained with the first one. Finally, a quantitative analysis or parallel sessions involving many more stakeholders is suggested. In fact, due to time limitation and available resources only a small sample was selected, whereas for cross-sector collaboration studies a broader range of stakeholders can enrich the results obtained.

To conclude, we believe that this work can be a great inspiration for practitioners. The design it together platform can be a model for entrepreneurial universities and private partners that look at building a structured, engaging and open platform for outcome embedding. In addition, the platform has a strong focus on the doing and the use of design tools and techniques, considering them as means to transcend the stakeholders’ barriers and obstacles. To our understanding, the application of these methods can be useful to create successful cross-sector collaboration also between different domains, such as corporate-NGOs, public-private partnerships, and complementary businesses. The use of design methods as cross-sector boundary objects can inspire and act as enabler for new cross-sector boundary groups (e.g. foundations) that look at creating new enthusiastic and successful cross-sector boundary experiences.

Baldini Luca  
I come from Rome, where I developed my interest for Arts, Aesthetic and Function. I did my Bachelor of Art in Product Design at the High Institute for the Artistic Industries of Rome (ISIA Roma Design). There I could learn how to combine products and services into a synesthetic experience, involving graphic design, branding, service design and meta-design. After completing successfully the BA, I moved to the Netherlands to pursue the Master of Science in Strategic Product Design at the faculty of Industrial Design
Engineering of Delft University of Technology. In the past 2 years and a half I investigated the different perspective on innovation and strategy applied to the product-service-user interaction. During this time, I also had the opportunity to move to Paris for 7 months where I worked for one of the most successful branding, digital and storytelling agency in France. Thanks to both Dutch and French experiences, I steered my interest towards the digital design and the service design world, including the cooperation between different stakeholders thanks to Design Thinking and Design Doing. This is the first paper I wrote and it is part of a broader and more extensive work done during my MSc Thesis.

**Calabretta Giulia**

I was born and raised in Italy, where I developed my creativity, curiosity and sensitivity for different aspects of design. I decided to cultivate my inclinations in a business context. Thus, my background and career before TU Delft are in the fields of management and marketing. I graduated in Business Administration (minor in Marketing) at Bocconi University in Milan, with a thesis on how iconic fashion designers transfer their stylistic identity into recognizable brands that survive
designers’ work life. I then moved to Barcelona, where I got my PhD in Management Science from ESADE Business School. My dissertation studied market acceptance of sustainable technology, with focus on the role of product design. After a two-year Post Doc at BI Norwegian School of Business (in Oslo), I joined TU Delft for doing research on the strategic role of design in companies’ innovation strategy. Over the years I have also been doing some freelance consulting in marketing for education institutions.

De Lille Christine

Christine De Lille is an Assistant Professor at the Delft University of Technology, the Netherlands. She investigates ‘Designing User-Centered Organisations’ with a focus on the practice of small to medium-sized enterprises (such as Difrax, Bammens and Alrec Displays), supporting organisations (such as the Dutch Chamber of Commerce and Flanders InShape) as well as the aviation industry (for companies such as KLM, Schiphol Airport and Zodiac Aerospace). Main areas of her work include service design and user-centred design, and how a user-centered perspective impacts and transforms organisations. Christine is a member of the Design Research Society, co-founder of its Design Management Special Interest Group, and organizer of various conferences (such as Mobile HCI 2008 and IASDR 2011). Christine De Lille lectures primarily in the MSc. programmes ‘Strategic Product Design’ and “Design for Interaction” at her faculty in Delft, and is also a frequent guest speaker to other universities and schools as well as various networks in practice, such as the Dutch Design Management Network.
Solution Generation Design Profiles: Reflection on "Reflection in Action"

Shoshi Bar-Eli, School of Design and Innovation, College of Management Academic Studies, Rishon Lezion, Israel, bashoshi@colman.ac.il

Abstract

Solution-generation design behavior in general, and "reflection-in-action" in particular, can serve to differentiate designers, recognizing their personal reflecting when designing. In psychology, reflection is found a more robust tool to enhance task performance after feedback from a personal "device" that generates the process itself while interacting with visual representation. Differences among students' interior design processes appear in their solution-generation design behavior. A “think aloud” experiment identified solution-generation behavior profiles. Qualitative and quantitative methodologies showed how design characteristics unite, forming patterns of design behavior. A comprehensive picture of designers’ differences emerged.

The research aimed:

- to identify individual design students’ solution-generation profiles based on design characteristics.
- to show how reflection-in-action appearing in the profiles can serve to predict how novice designers learn and act when solving a design problem.
- to enhance the uniqueness of reflection-in-action for designers as distinct from reflection in other fields.

Four distinct solution-generation profiles emerged, each showing a different type of reflective acts. Identifying reflection-in-action type can robustly predict how designers develop design solutions and help develop pedagogical concepts, strategies and tools.

Keywords: reflection in action, design behavior, solution generation, individual difference, design characteristics, design process

The research that forms the foundation for this paper is based on two main principles. The first is that acquiring a personal process of design, i.e., a way of thinking about making a design, is a central objective of the design process; and the second is that understanding the differences among designers is key to optimizing the design process of each designer, by allowing each of them to trust their process and share it with others. The design process can be analyzed according to two main phases of problem formulation and solution generation. In this paper, we choose to relate only to the phase of solution generation.

We address two issues: Design Behavior Profile, and Reflection in Action. The Design Behavior Profile is shaped by a combination of design characteristics, which generate the individual's innate way of designing. We define a design characteristic as a single aspect of behavior in the context of designing, which demonstrates the individual’s habitual mode of solving design problems. A combination of design characteristics that is shared by a group of designers in the
way they design can be defined as a Design Behavior Profile. Such profiles represent various approaches to formulating design problems and developing solutions. While analyzing the various profiles, we found that the design characteristic of "reflection in action" or self-assessment is key to differentiating designers. Looking at the model of solution generation profile, one can predict the characteristics of reflection/assessment by other characteristics such as framing (or main preference), solution type and the resources used while designing. The main goals of this paper are:

- To identify individual solution generation profiles of design students on the basis of design characteristics.
- To show how reflection in action is manifested within the various profiles and can be a used as predictive tool for the way novice designers learn and act when solving a design problem.
- To enhance the uniqueness of the notion of reflection in action for designers as opposed to the use of reflection in other fields, such as psychology.

In this research, exploratory qualitative methods were implemented to infer various designing characteristics. Then quantitative research methods were used to determine how these characteristics act in unison and form comprehensive patterns of design behavior. Conducting the research using a relatively large sample population of designers allowed for a detailed quantitative analysis that produced a wider range of results.

By analyzing the combinations of the design characteristics of solution generation phases, we identified various design behavior profiles: Realization Oriented Profile; Learning Oriented Profile; Designer Oriented Profile; and Assessment Oriented Profile. Each design behavior profile is shaped by a combination of designing characteristics that generate the individual's innate manner of designing. The findings demonstrate that design behavior profiles guide various approaches to solution: focusing on the designer, focusing on the given problem and focusing on the end solution.

Design behavior and individual differences

One of the challenges of design research is to capture the design process as a complex entity. Some researchers have mainly aimed at capturing an objective representation of the design process (Gero and McNeil, 1998; Purcell et al., 1996; Suwa et al., 1998); others have attempted to understand designers’ behavioral patterns, concentrating on specific aspects of design behavior (Akin and Lin, 1995; Cross, 2001; Goel, 1995; Goldschmidt, 2001; Schön and Wiggins, 1992). Within their frameworks, the researchers performed in-depth investigations and arrived at a profound and detailed understanding of how design behavior is expressed throughout the actual process of designing. Due to this in-depth approach, most of the studies were conducted on relatively small samples, therefore placed little emphasis on distinguishing differences among designers.

Identifying individual differences in designing in reference to various design behavior characteristics presents a great challenge. The importance of understanding the differences among designers stems from our wish to optimize design education, in the sense that helping each student find his/her appropriate process is an important goal. In the words of Ochsner (2000): "Not the problems themselves or the solutions alone are the aim of design education.
Rather, the aim is learning a personal process of design – a way of thinking about making architecture" (p. 195).

Schön (1998) notes the “oblique” way in which studio instructors challenge students to enter into the design process. He describes an experiment whereby he tried to learn more about the knowledge and reasoning of practiced designers. He observed that different designers construed the task they were asked to perform in very different ways. Their different interpretations of the task led them to wholly different global patterns of designing because they used different design rules. One of the main questions refers to the different judgments designers make when designing.

When referring to design education, in many cases design instructors will judge their students as "not progressing" or "not successful" because the instructors were unable to address their pedagogical approach and their ways of instructing according to their students' way of thinking and doing design.

**Reflection in action**

All across different psychological domains there is a great deal of research on the notion of reflection. Studies refer to systematic reflection, which serves as a key tool in learning from experience. Ellis, Carette, Anseel and Lievens showed that through systematic reflection people can learn from both their successes and their failures (2005, 2014).

Reflection in action can be seen as a unique demonstration of reflection that is inherent to the design process and problem solving. Donald Schön, with his notion of the design process as "reflection in action," introduced a critical modification in the way design teaching and learning is viewed. His concepts, which were presented in his best-known books *The Reflective Practitioner* (1983) and *Educating the Reflective Practitioner* (1987), have been seminal in research into design activity for the past 30 years.

In his attempt to understand the central educational features in design and the notion of the design process, Schön analyzed audio-taped protocols from student-teacher sessions in the design studio. Schön's main claim was that design is a "reflective conversation with the situation"—namely during the design process the designer enters into a "frame experiment," a "dialogue" with the materials of the situation. In the process, the designer makes tentative operational moves while the materials "talk back" to the designer, constraining and shaping subsequent moves.

In an interview with John Bennett, Schön discusses the activity of design and speaks about three kinds of reflection: reflection in action, reflection on action and reflection on practice. He says: "Reflection in action is closely related to the experience of surprise. Sometimes, we think about what we are doing in the midst of performing an act. In architectural design the ‘performer’ frequently conducts an experiment in the form of series of drawings combined with talking” (Bennett, 1996, 172). Bar-Eli's (2010) analysis of sketches and their role in differentiating designers defined three distinct sketching profiles, which characterize designers' use of sketches as a tool for thinking and communicating ideas. Particularly today, when digital tools offer
endless possibilities for representation, designers may benefit from using sketches in order to clarify and communicate their design ideas and choose the precise tool for developing them into solutions.

In the second type of reflection "the designer exhibits a reflection on action, pausing to think back over what she has done in a project, exploring the understanding that she has brought to the handling of the task. She may, for example, construct a new theory of the case, reframing the problematic design situation in such a way as to redefine, interactively, both means and ends" (Bennett, 1996,172).

In the third kind of reflection, reflection on practice, the designer may surface and criticize tacit understandings that have grown around repetitive experiences of designing. For example, he may become aware of having fallen into an unfortunate pattern of design behavior, such as "falling in love with an initial design idea," or "trying to build a diagram" (Bennett, 1996, 172). The notion of "reflection on action" and "reflection on practice," although present throughout the design process, can be closely related to systematic reflection because it is used as a post-action tool, in order to "draw lessons from prior experiences and eventually to behavioral change (behavioral effect)" (Ellis, Carette, Anseel and Lievens, 2014; 68). In analyzing systematic reflection, Ellis and Davidi assert that it serves three functions: self-explanation, data verification and feedback (2005), and that all three must be combined in order to become an effective learning tool. The three functions are seen as an integrative system, but there isn't any reference to the weight of each in differentiating people.

Schön's work had a great influence on research of design, enabling the researcher to place an emphasis and observe the designer's "conversation with the situation" more closely, as he asks new questions about the content, structure and the design process, and develops a new taxonomy of design problems and frames.

The notion of reflection in action is closely related to the characteristics of assessment and evaluation. In many cases it can be used interchangeably. Lloyd and Scott (1995) state that "evaluation is the process of guiding and controlling design by making subjective decisions about problem, solution or process. It is similar in some respects to Schön's idea of 'reflection in action'" (p. 385). Jonassen (1997) describes this process as monitoring the problem’s space and solution options, and agrees with Lloyd and Scott that it occurs throughout the entire process, as a reflective procedure in which the designer "must have some epistemic knowledge about an alternative solution, and then develop a strategy for framing the problem, and selecting and synthesizing a unique solution" (p. 82).

The act of iteration or redesign, which Blessing treats as process backtracking (1992), was discussed in depth by Adams et al. (2003). These researchers describe the act of iteration as including "self-monitoring, clarifying and examining activities. These observations of self-monitoring activities include reviewing and evaluating progress, self-monitoring understanding and searching for or being open to finding potential solution failures" (p. 286). Frequently these monitoring and assessment activities result in returning to the problem requirements, redefining the problem, and revising the solution elements. The individual differences in the assessment and
evaluation processes, and how they influence each individual designer’s subjective choices, will play an important part in the analysis of the student-designers' design behavior and processes.

**Method**

This research implements mixed methods: qualitative research methods are implemented to infer the various designing characteristics; then quantitative research methods are implemented to determine how these characteristics act in unison and form comprehensive patterns of design behavior.

The population of this research was 50 interior design students on different levels of study in an interior design department. The participants took part in a "think-aloud" design problem-solving experiment involving two design problems, and were allocated up to 30 minutes to complete the task. The entire process was videotaped, and the materials (including their verbalization) were used to create protocols, which were then analyzed using a coding scheme pertaining to designing characteristics.

Qualitative content analysis was performed on the first twelve protocols in order to identify differences and similarities between subjects. We began by using a large number of characteristics for the first twelve participants. The analysis allowed us to determine which characteristics would later be used in the quantitative phase of the research (design behavior profile identification).

The quantitative analysis was performed on the entire experiment population. In this article, we focus on the solution generation phase and the specific characteristic of reflection in action—or assessment and evaluation.

**Results**

**Solution Generation Profiles**

From analysis of the variables relating to solution generation, we identified four design behavior profiles: **Realization Oriented Profile, Learning Oriented Profile, Designer Oriented Profile** and **Assessment Oriented Profile**. We used AMOS (Analysis of Moment Structures) to perform a Confirmatory Factor Analysis. The factor loading of the solution generation phase is presented in Table 1.

The CFA (Confirmatory Factor Analysis) results are presented in Figure 1. The four profiles were built from the solution generation characteristics with the highest factor loading, and then analyzed to check their inner paths\(^1\), i.e., the way the solution generation characteristics are related in a specific factor.

\(^1\) Since we found complex relations here among characteristics, we used Structural Equation Modeling (SEM via AMOS) in order to find the different paths among characteristics. SEM allows us to introduce multicollinearity into the models and to model mediating variables, rather than be limited to an additive model, as in OLS regression.
Solution Generation Profiles Mapping

a) Realization Oriented Profile (Profile S-1)

The profile displays a significant positive correlation among the designing characteristics. When examining the complete profile, all the designing characteristics of detailed solution—the use of examples from the design world and thinking in a concrete manner—explain the characteristic of
testing the design idea in reality. In other words, the above characteristics influence and predict the nature of dealing with design ideas and solutions in the practice of design (Figure 2)

![Diagram](image_url)

**Figure 2**: Solution Generation Profile S-1 – Realization Oriented Profile

The profile model was accepted as having a good model fit, i.e., the overall model fits not only the sample data but also the population data. The profile displays a significant positive correlation between the characteristics of detailed solution and the use of examples from the design world. That is, students who tend to use examples from the design world also tend to detail their design solutions during the process of solution generation. The profile path includes these designing characteristics as positively affecting concrete thinking (they vary in the extent of their effect; detailed solution has the greatest effect on concrete thinking).

The concrete thinking characteristic affects the assessment characteristic of testing the design idea in reality; the complete path model explains 32% of the assessment characteristic variance.

---

2 *Chi Square goodness of fit* test was not significant (p=0.104). A significant chi square indicates lack of satisfactory model fit.
b) Learning Oriented Profile (Profile S-2)

When the complete profile is examined, all the designing characteristics—emphasizing functional issues and rules, use of examples from reality (experiential examples) and use of spatial issues and rules—explain the characteristic of testing the design steps during the solution generation process. In other words, the above characteristics influence and predict the testing the design steps characteristic (Figure 3).

![Diagram showing the relationship between functional issues and rules, examples from reality, spatial issues and rules, and testing design steps.]

Figure 3: Solution Generation Profile S-2 – Learning Oriented Profile

The profile model was accepted as having a good model fit. The profile shows a significant positive correlation between the characteristic of use of functional issues and rules and use of examples relating to the real world—that is, students who tend to use examples from reality also tend to use functional issues and rules in their solution generation process. The profile path includes these designing characteristics as positively affecting the use of spatial issues and rules, which affect the assessment characteristic of testing the design steps; therefore, the complete path model explained 22% of the assessment characteristic variance.

c) Designer Oriented Profile (Profile S-3)

The complete path displays the designing characteristics: using abstract thinking, using examples from one’s personal world and emphasis on strategic issues and rules that are uncorrelated, as explaining the characteristic of designer’s personal awareness. In other words, students who display this profile tend to use abstract thinking, which leads them to use either one or both examples from their personal world and to emphasize strategic issues and rules (relating to design tools and processes). This affects their behavior of being aware of their design processes during the solution generation phase. The extent of the effect of emphasizing strategic issues and

---

3 Chi Square goodness of fit test was not significant (p=0.540).
rules is greater than the use of examples from one's personal world. The complete model explains 32% of the variance of the assessment characteristic (Figure 4).

![Diagram](image)

**Figure 4:** Solution Generation Profile S-3 – Designer Oriented Profile

d) **Assessment Oriented Profile (Profile No. 7)**

The profile includes a significant positive correlation between the designing characteristics: examining the design idea according to problem requirements and testing the final design solution according to the initial idea; that is, students who tend to examine their design ideas with the problem requirements in mind also tend to test their final design solutions according to their initial ideas or concepts (Figure 5).

![Diagram](image)

**Figure 5:** Solution Generation Profile S-4 – Assessment Oriented Profile

**Discussion**

We identified differences between students' design behavior based on combinations of design characteristics that generated the individual's innate manner of designing. The four profiles distinguished in the solution generation phase proved significant; they were displayed by 80% of the participants who developed design solutions.
In analyzing the four solution generation profiles, we see that they may be divided into three approaches to design: (1) the personal approach, which focuses on the designer, and his individual process of idea generation focuses on the personal design process and on theorizing design ideas (S-3 – Designer Oriented Profile); (2) the information driven approach, which focuses on the given assigned design problem and focuses on solution generation as a learning experience (S-2 – Learning Oriented Profile); (3) the realistic approach, which focuses on the end solution and its implementation in reality (S-1 –Realization Oriented Profile and S-4 – Assessment Oriented Profile directed at the end solution and its assessment).

The solution generation profiles model (Figure 6) includes four components: (1) main preference and/or solution type; (2) use of resources; (3) assessment type. Observing the model, we see that the resources used by student-designers and the manner in which they assess their process and solutions are consistent in all profiles. The direction of the arrows that represent the relationships between the components all affect the way student-designers reflect and assess their processes and solutions. This discussion analyzes in depth the profiles, with emphasis on the type of reflection in action and assessment. We also address the differences and similarities between reflection in action as manifested in the profiles and the notion of systematic reflection in psychology.

![Figure 6: Model of Solution Generation Profiles](image)

**Realization Oriented Profile (S-1)**

The Realization Oriented Profile (S-1) was identified in student-designers who sought solutions that could be tested in reality and implemented in the practical realm. To reach a solution that could be tested based on practical criteria, these student-designers believed that solutions had to be detailed and clearly explained. Throughout the entire process they tended to use within-domain knowledge resources—from the design world and from the profession, which suited the type of solution they chose to develop. These resources resemble the "objective intention" of designers, as expressed by Downing (2000, 100). She found that some designers, when describing places, were less concerned with their personal experience and feelings than with an analytical and objective description.
The use of resources helped student-designers to detail their solutions by repeatedly referring to examples as they developed their design. Moreover, it affected the way they assessed their progress by continually asking themselves whether the solution could be implemented in reality, and whether it could actually be built. They expressed the focus of their solution in statements, for example: "I will design it in a precise and professional manner so I can see if the ideas can withstand the test of reality"; "only someone who stands here can see what happens on the highest shelf"; "I need to relate to the different hours of the day and how people enter the space."

Relating this type of reflection to the issue of systematic reflection, we can say that the students placed greater emphasis on feedback due to their primary focus on the end result: if their design could actually be implemented in reality.

Awareness of this type of design behavior can be applied to learning in design education by showing students precedents and demonstrating their contribution to both design development and the application of their solution in practice.

**Learning Oriented Profile (S-2)**

The Learning Oriented Profile (S-2) was displayed by student-designers who remained within the parameters of the given problem and regarded the assignment as a learning experience. They were not interested in reaching a detailed end solution, but in presenting the best linkage between function and space. Throughout the entire process they developed their solutions based on the relationship between functional and spatial aspects, using rules and themes associated with functionality and spatial language. To acquire better understanding of this relationship, student-designers used experiential resources.

This profile can be seen as a combination of both the designers' "objective intentions" (Downing, 2000, 100) and "experiential intentions" (Downing, 2000, 97). Objective intentions are represented by the continuous analysis and description of the spatial attributes and the functional rules. Experiential intentions are represented in reference to the designers' experience in situations evoking the desired atmosphere within the current designed space.

The focus placed on the relationship between function and space, and the use of experiential examples, affect the manner in which the assessment is performed—in this case, repeat testing of design steps throughout the solution generation phase. Testing plays several roles, including keeping track of the design moves; checking the spatial aspects of the design; inspecting its uniformity, as manifested in the relationship among the functional, spatial and experiential aspects of the design. Testing often sets the pace for the progress of the solution generation process. This type of reflection is represented by phrases like: "I'm looking at plans, trying to figure out what else I have in this space" (looking at the given data of the design problem) "I think I made a good decision to lower the ceiling because it's not comfortable to be in such a narrow and tall space"......" I have to look back at all my ideas and to see if they really work within the space I designed. Does the movement in space, actually work?... I have to emphasize the main element under the window, so people will have something to look at..."
When relating this type of reflection to the issue of systematic reflection, we can say that there is greater emphasis on data verification due to the student-designers’ main focus on the process as a learning experience, and being involved in checking the data given in the design task and if it is used properly in the process of developing the design solution.

These findings can be applied to learning and design education by encouraging students to use experiential resources, and thus contribute to better use of functional and spatial issues and rules in the generation of solutions.

**Designer Oriented Profile (S-3)**

Student-designers who displayed the Designer Oriented Profile (S-3) were mostly preoccupied with their own personal design process. Their objective was to develop a general solution that was personal, and that could serve as a basis for future development based on their design ideas, processes and tools. These student-designers, as opposed to student-designers acting upon all the other design profiles, were not interested in arriving at a detailed solution; nor were they interested in relating to the specific data of the given space. Throughout the process, they used a rich vocabulary of personal resources in the form of abstract visual images and analogies. These resources helped them enrich their design ideas and produce a formal design language. These participants also relied on procedural knowledge, referring to the design tools and processes that they used in the process.

It is interesting to note that reliance on procedural knowledge in the use of design tools was evident during the assessment, when the student-designers reflected on the actions forming the design process. Reflection on the process is expressed in statements such as: "I do things without thinking, and even if the sketch doesn’t look right to me I continue to develop it so it will look nice"; "My purpose is to arrive at a general language that will dictate the type of conceptual model and sketches that will follow"; "What I'm doing here is actually making a conceptual model and the building in the end will look entirely different."

This profile may reinforce the observation of Murty and Purcell (2007) with regard to experienced architects who were identified as process orientated designers. In this research, we showed that this orientation is also displayed by students, and not only experienced designers, as observed by Murty and Purcell.

When relating this type of reflection to the issue of systematic reflection, we can say that there is greater emphasis on self-explanation due to the student-designers’ constant involvement in discovering their actions while designing.

**Assessment Oriented Profile (S-4)**

This fourth solution generation profile consists of two design characteristics: evaluating solutions according to the initial proposed idea, and doing so according to the design problem requirements. At times, designing on the basis of this profile occurs in conjunction with designing according to other profiles. In other words, participants who display this profile in combination with other profiles tend to reinforce the act of assessing their results, in addition to following their progress throughout the solution generation phase.
Nevertheless, students who designed on the basis of this profile were constantly preoccupied with evaluating their solutions, to verify that they were succeeding in implementing their own design decisions and fulfilling other requirements (in this case the problem requirements). Often, the evaluation was performed by describing the final result, and commenting with phrases such as "This is like the idea I wanted to develop"; “My initial idea was... so I would like to keep it like that"; "I like it this way."

Although this profile is relatively narrow due to its sole focus on evaluation, it can be easily detected by design teachers and used to encourage students to evaluate their final design with regard to both their ideas and their teachers' requirements. We observed that many of the student-designers, when developing their solutions, designed on the basis of this profile in combination with other profiles. This finding underscores the role of reflection and assessment in the design process and reinforces the need for greater awareness of this profile's design characteristics. It would be interesting in future research to study the effect of extensive use of assessment and evaluation on the student-designers' results in terms of quality and originality.

Studies relating to systematic reflection have further shown that its effectiveness depends on situational (e.g., reflection focus) and person-based (e.g., conscientiousness) factors (Ellis et al., 2014, 70). We believe that understanding the various types of reflection in action and assessment of designers can be used for further research in systematic reflection during people's activities. This affirms Ellis’s view: "Given today’s unrelenting pace and the abundance of activities in which people are involved, future researchers may want to investigate how to effectively integrate systematic reflection within the busy daily environment of the learner."

**Conclusion**

Creating awareness in both design instructors and students of differences in design behavior may add another, beneficial, dimension to design teaching and learning. Design education may be optimized if we use the knowledge acquired about design behavior to help students find the approaches and processes that are most suitable for each.

The notion of reflection in action and reflection in general must be firmly related to individual differences and can serve as a tool to perceive and predict learners’ behavior. Distiguishing various ways reflection may encourage choosing the right way of teaching and learning for the particular learner and help him, through reflection, to improve his abilities.

Teachers/instructors will be able to make decisions regarding the way they give their students guidance. They could raise their students’ awareness of their strengths and of the possibilities offered by other approaches.

We believe that teachers will be able to develop a specific design pedagogy addressing their students' problem-solution orientation tendencies, and increase their awareness of the design phases and their contribution to the overall design process.

Two blind spots in design thinking

Estelle Berger, Strate School of Design, Sèvres, France, e.berger@strate.design

Abstract
From the 1980s, design thinking has emerged in companies as a method for practical and creative problem solving, based on designers’ way of thinking, integrated into a rational and iterative model to accompany the process. In companies, design thinking helped valuing creative teamwork, though not necessarily professional designers’ expertise. By pointing out two blind spots in design thinking models, as currently understood and implemented, this paper aims at shedding light on two rarely described traits of designers’ self. The first relies in problem framing, a breaking point that deeply escapes determinism. The second blind spot questions the post project process. We thus seek to portray designers’ singularity, in order to stimulate critical reflection and encourage the opening-up to design culture. Companies and organizations willing to make the most of designers’ expertise would gain acknowledging their critical heteronomy to foster innovation based on strong and disruptive visions, beyond an out-of-date problem solving approach to design.

Keywords: design thinking, problem framing, strategy and tactics, design management, design culture

Introduction

Introduced as a communication tool to clarify designers’ thinking and working process, design thinking met with undeniable success in companies and organizations, and developed into a panel of tools, connected by a methodology to accompany design process. Widely reinterpreted by design professionals, consultants or researchers, the basic model may vary, but a common ground remains in summarizing the key phases of design projects. Academic research started investigating the way designers think in the 1990s, in particular from the pioneering contributions of Archer (1979), Cross (1982) and Schön (1983). There is now a large body of literature on design thinking, holding a pivotal place in design research and pervading education. Leading institutions around the world publically promote the teaching of design thinking, even for non-design backgrounds. A “discourse community” is built up, constructing meaning through the use of language and signs, claiming power to legitimize design activity (Ghassan, 2016).

This position paper aims at pointing out two blind spots in design thinking as it is currently understood and implemented. Two archetypical and recognized design thinking models are used as a baseline for discussion: the Double Diamond, from the British Design Council (2005), and the d.school model, developed by Hasso-Plattner Institute and Stanford University from IDEO’s work (2001). Both of them show a linear process, divided in four to six stages, while allowing episodes of divergent thinking (double diamond) and feedback loops (d.school). Cross-disciplinary teamwork and early testing with potential users are shared focus.
These models give a generic pattern to monitor design projects, in order to foster innovative ideas, quickly transformable intro implementable solutions in companies. But do all design projects need to share such goals and means? We are defending the irreducibility of design to methodology-driven problem solving. More than methods, design involves values and visions that remain in the blind spot of design thinking models. Those look at the how of design – “doing the thing right”. But design is above all concerned by the why – “doing the right thing”. Besides what is done, how and why it is done, successful innovation depends in part on an interior condition, the inner place from where individuals or collective entities operate (Flowers et al., 2005). Drawing upon the pioneering work of social scientist Kurt Lewin and recent research on brain plasticity and neurophenomenology, Otto Scharmer has been working to describe this blind spot of psychological experience from which our attention, intention, and action originate when we engage with others and with ourselves. By borrowing the concept of blind spot, we aim at shedding light on two rarely described traits of designers’ self, looking below the surface of design thinking models. Once explored and described, we hope these perspectives may broaden the view on designers’ expertise, beyond innovation problems solving.

First, this study investigates problem framing. Design thinking models mention it as a key phase, graphically integrated in the process. We take the stance that questioning the initial design brief is a breaking point that deeply escapes determinism, hence should be taken into account accordingly. The second blind spot is simply absent from models. Consultants promoting design thinking may consider design is not longer involved after delivering an outcome, or launching a product. But companies and organizations need long-term, process- oriented design accompaniment to learn from the past as well as from the future as it emerges. The paper ends up portraying the critical heteronomy exerted by designers, drawing a few directions for companies to make the most of design culture beyond the restrictive design thinking.
The mystery behind problem framing

From problem to mystery

Both models start with “discovering” or “empathizing” phase, engaging fine-tuned observation for a deep and human-centered (Buchanan, 2008) understanding of situations. In this phase, designers collect a huge amount of field data (interviews, notes, state-of-the-art studies…). Ethnographic tools help gathering and analysing this material. This work may be handled by trained designers or in collaboration with psychologists, sociologists or anthropologists… aiming at developing the broadest view on human experience, knowing that exhaustiveness is unreachable.

In doing so, designers are supposed to spot relevant pain points, entering the second step: defining a problem to address. This means integrating disparate pieces of information into a focused vision of the situation. Divergent thinking gives way to convergence in setting the final design brief. The moment is key because all stakeholders, from client to design team, need to agree on the project’s terms and goals. In this state of becoming, different alternatives coexist. Without being able to explore them all, a choice is to be made and a question formulated, which will be the reference framework to evaluate final outcome. In other words, the following iteration phase is merely an exploration within the problem framed. The point is, there is no single global vision of a situation, no matter how talented or experienced the designer is. Diverse ways and variations may fulfil a design brief. This set of patterns remains the realm of arbitrary and instinct.

In this line, the term “problem” should be replaced by “mystery”. Whereas problems are capable of rational solutions, mysteries involve subjectivity. They do not exist independently and are meta-problematic, unsolvable by technical means. Hence the well-known aphorism: “Life is not a problem to be solved but a mystery to be lived” (Marcel, 1935).
Insights and inspiration

From a cognitive point of view, the enigma around problem setting/framing has been a recurring topic in the literature (in particular Schön, 1983/1992; Simon, 1973; Cross, 1984). It is defined as the point when designer’s judgment is shifting the project from a sum of identified parameters to the unknown, the unpredictable (Moholy-Nagy, 1947). How does this happen? It appears that designers are able to tacitly make “qualitative judgments” without being necessarily able to explicit the criteria on which they base them (Schön, 1992). In complex environments, where interdependencies and uncertainty rule, where no objective view of situations exist, analytic approach is inefficient. Designers mobilize their subjectivity to identify and frame relevant issues, relying on insights from the observation phase that are individual and qualitative rather than quantitative. The criteria for selecting such inspiring elements are mainly personal and involve “[the designer’s] creativity, way of approaching the world's problems, [his/her] own history, learning style and view of the world” (Lawson & Dorst, 2009).

First studied by Gestalt Psychology in the early part of the 20th century, insight learning is a type of cognitive process able to address a problem that cannot be solved in a conventional or logical manner (Köhler, 1925). Suddenly seeing the problem in a new way creates a so-called “eureka moment”. The problem is that such creative breakthrough is not directly observable, and relies for a large part on subconscious mechanisms.

Indeed, insights are at the basis of designers’ thinking. Designers “think, dream and imagine” (Branzi, 1997), and “original and interesting ideas rise from a well-trained subconscious” (Wynants & Cornelis, 2005). Inspiration happens when intuition meets a latent potential, like waiting for Kairos. This ancient Greek figure personifies luck and favourable moments. A tuft of hair hanging over his face allows seizing him when arriving. But the back of his head is bald, meaning when an opportunity is gone it cannot be re-captured.
This metaphor depicts the state of mind from which insights happen: standing ready to seize the unpredictable, which may come from outside the project’s framework. It requires balancing sensitivity and judgment. As the French mathematician Henri Poincaré used to say, difficulties are sometimes overcome through hard work, and sometimes by a sudden and unexpected illumination “during a walk along a cliff”. Poincaré’s inspiration was obviously not in the cliff, but in his brain experiencing emotions, recalling analogous situations… Even in hard sciences, ideas come from a subtle balance between methodical work and inexplicable illumination (Villani, 2012). Such relativity rules out any notion of designers being objective. Each one rather expresses, from diverse experiences and personality traits “what [their] individuality records, like a seismograph, from human phenomenon” (Mendini, 1984).

The irrationality of designers

However, design thinking models remain silent about the tacit and irrational judgments made by designers. They are yet crucial, since any result is to be judged according to the problem initially set. Admitting that choices are based on instants of subjectivity and intuitive shortcuts destabilizes linear methods.

“There is a causal relationship between problems, processes, and solutions in science – a relationship that is wholly absent in designing. Problems do not determine the process, and neither the problem nor the process determines (a) solution.” (Beck & Stolterman, 2015) In both cases, novel entities emerge, that could not have been predicted from what was before: new points of view, new perspectives – in the realm of design, new concepts and meanings. But different modes of emergence are to be distinguished. Combinatory emergence is an evolutionary process where an expansive phase (in which many possibilities are generated) leads to a contractive phase (in which critical selection of “adequate” or “best” possibilities is made). Although combinatorial systems may differ in numbers of possible combinations, their set of possibilities is closed. In creative emergence, on the other hand, new primitives are formed, permitting the space of combinations to expand (Cariani, 2012). This is what Schön (1983) referred to as “generative metaphors”.

Figure 5: Kairos, Greek figure of favourable moments
As the first mode of emergence means applying methods, the latter means designing. Designers often say there is no “good answer” but a diversity of propositions that are not mutually exclusive. Giving twenty designers the same brief inevitably results in twenty different projects. More important, evaluating the quality and relevance of these solutions in relation to each other might be impossible.

Here is a limit for theory, concerned with universality and reproducibility of results. On the contrary, design practice aims at singularity (Hatchuel, 2015). While any object of scientific study represents an example from a broader category, design considers what makes an object or situation unique. This singularity stems as much from contexts as from designers’ individualities.

**Giving shape to the world**

Therefore, not every part of design projects can be achieved collectively. In particular as initial parameters melt into a whole that transcends the sum of its parts, following a well-known Gestalt principle. This transformation process goes beyond analysis-synthesis and logical thinking, which makes it hard to share or distribute. It remains a part of the black box of creation – more than creativity.

Though design is basically not self-expression (Hara, 2003), designers share with artists the same sensorial and sensible expression and communication tools (Moholy-Nagy 1947; Papanek 1972). Designing means shaping objects, services, systems or relationships… Whatever the outcome, designers are experts at giving physical embodiment to ideas. It should be clarified that aesthetics is more than appearance; it underlines the importance of our sensitive perception of the world. In this line, designers form and “reform” (Huyghe, 2014) the objects surrounding us. In multidisciplinary teams, professional designers often naturally transpose ideas, thoughts or discussions into tangible representations – be they deliverables or intermediary objects.

This is the first vocation of design, still in our more and more immaterial times. Designers of the 20th century used to shape physical materials; today they also shape experiences and patterns of relationships. This extension of the realm of design represents a challenge for designers to step forward, though it remains somewhat cloudy.

**Is it over when delivered?**

**Embracing the full lifecycle**

![Diagram](https://via.placeholder.com/150)

**Figure 6: Delivered, the last stage of design thinking**

Rather than producing finite solutions, most designers assume providing “representations of things that might work” (Gero, 2013). Such caution makes sense, because uncertainty
doesn’t disappear during the design process. It is rather diffracted, taking design another step further from a deterministic problem solving activity. Designers are called to create “simplicity” (Kluger, 2008): enhance affordance and evidence without impoverishing the diversity of uses. They project themselves into the artefacts’ future life, and try to design them accordingly. But as reality always remains polymorph (Latour, 1992), the ideal of a convergent outcome is bound to be unreachable.

Though, all design thinking models end with implementation. What happens next? Products or services are never univocally adopted. Some fail to find a market, audience or to meet users’ needs; some are subject to misuses or unexpected practices. The outcome can be positive, showing creative appropriation, but also negative, exacerbating the counter-productive (Illitch) or harmful (Baudrillard) potential of design. Just like design tackles “wicked problems” (Rittel & Webber, 1973), it may also create wicked solutions!

In the social innovation field, designers are particularly vigilant about such unintended effects of action (Papanek, 1974). But every object should be concerned: human behaviours and relations transform functions, meanings and values. Designers’ good intentions may lead to adverse effects, as shown by the example of Modernist architecture. Initially based on social concerns, “machines for living in” (Le Corbusier) are now roughly criticized for alienating people. Though, as pointed by a contemporary corpus-led discourse analysis study, the design thinking research community is reticent to discuss negative consequences of design, “unwilling to broach areas which may potentially cause discomfort” (Ghassan, 2016).

It is indeed a matter of responsibility for designers to track what happens after the project process, basically for sustainability reasons. The lifecycle of artefacts must be taken into account, not only through planning but also on an on-going basis in real life context. Are the needs fulfilled? What patterns of use emerge? Upgrading, repairing, recycling or remanufacturing are also design strategies to plan for and arrange.

The concept of “open objects” coined by Simondon (1958) argues in this sense. Unlike closed objects, adapted to their technological context and hence doomed to obsolescence, open objects remain adaptable and withstand the evolution of human uses. As they can be fixed, hacked or improved along with technological progress, the course of time does not affect uses so much.

Open models

But openness is more than a pragmatic issue. Designers are above all concerned with experience, which involves more than the traditional functional, sensorial and emotional dimensions attached to design. Time, social relations, purposes and motivations combine, shaping unique and transformative experiences over time (Dewey, 1934). Today, successful designs offer more than products or services, caring for holistic experiential dimensions. It was proven that living experiences is more memorable and transformative for people than consuming goods (Van Boven, 2005). In this line, artefacts need to be designed not as ends in themselves, rather as conditions for and supports to experience. An object is nothing but a “freeze frame” in a dynamical process of “transformations, associations and substitutions”, requiring designer’s arbitration or “negociation” (Latour, 2009; Bihanic & Huyghe, 2015). In a project context, status quo may seem achieved at the
end of the process, but this is hardly the case in real life. As pointed by the famous French designer Roger Tallon:

“Most people believe a project has a beginning and an end, like a movie. Not at all. There is no ‘Closing time!’” (Tallon, 2011)

From users point of view, a large part of experiences escape design intentions. But this does not mean designers should take no further interest after projects are delivered. On the contrary, they have a lot to learn from practical situations to compare and contrast their views on human behaviours, needs and aspirations. In this line, stubborn habits, opposition to recommendations, misuses or even hacking of rules are to be considered significant and legitimate, even to adapt design solutions afterwards. This allows to gradually enhancing the relevance of design propositions. Objects are no longer consumer goods but “in-process objects”, “becoming-objects” or “proto-objects” (Bihanic & Huyghe, 2015), that can be used as tools for observational studies.

In the digital world, lean or open source frameworks allow designers to maintain artefacts in a “neotenic state” (Beaubois, 2015) and to learn from diverse emerging practices. In other sectors, participatory or co-design processes deploy similar methods and tools, but most of the time ending up with a “closed” solution to implement. Consultancies and even in-house design teams often lose sight on their work once projects are considered finished. This makes them unable to gather feedback from direct and indirect users, at detailed and large scale, short and long-term, hence unable to learn from the challenges or limits encountered. Design thinking toolkits remain silent on this aspect.

Figure 7: Is it over when delivered?

A framework for practical wisdom

There is a need for more growing and generative models, valuing designers’ ability to slow down, keep open or reintegrate options into broadly linear and deterministic processes. As a project-based discipline, design considers what is possible rather than what was stated, taking “the world as design” (translated from German Die Welt als Entwurf; Aicher, 2011). Among all possible futures (Voros, 2001), designers try to lead the way towards the preferable ones. This implies defining strategies, while preserving latitude for adaptation or bifurcation if needed – in other words tactics. The French philosopher Michel De Certeau (1990) distinguishes between strategic vision – which is a synoptic, unified view of a situation, and tactical ways – which are multiple and adaptive. The latter characterise everyday life creativity, individuals being influenced by current rules and tools but never completely determined by them. In the same way, design activity is not closed strategy, following a linear timeline from past to future in a prescriptive manner. It rather fosters adaptability, proposing scenarios that leave space for people’s own ways of living. “The ultimate interest of design is to provide openings
and choices” (Huyghe, 2014).

Being more concerned by what happens than what was intended, design culture cannot thrive on methods systemizing paths to follow. A “designerly way of thinking” (Archer, 1979) involves practical wisdom and knowledge. In the same way, the early Greek concept of *phronesis* requires both intuition and ability to discern how and why to act. Linked to the figure of Kairos outlined above, it was translated as “mindfulness” or “prudence”.

This way of acting meets design practice as far as it is based on “reflection-in-action” (Schön, 1983). Just like ancient prudent Greeks, designers develop conducts from the unpredictable, aware that they don’t know what tomorrow will bring. This precludes predictive approaches aiming at quantifying risks, following a so-called precautionary principle. It is then to distinguish between prudence and precaution (Sage-Fuller, 2016; Huyghe, 2014), one being concerned with design, the other with calculation. Prudence does not hinder action, but requires ability to operate in uncertain environments, as a mindful and tactful practitioner.

**Impact for organizations**

**From the comfort of design thinking…**

In companies, while marketing, commercial and financial bodies all dread uncertainty, design does not only accept but also build from the unpredictable. As described above, designers are used to complex environments, handling interconnected and sometimes paradoxical parameters, and hazards are at the basis of the creative process.

On their side, design managers have the difficult task of balancing strategy and contingency. The challenge is to preserve the necessary freedom to create while integrating companies’ constraints and goals (Paris, 2008). Oddly, they need to reassure and convince that designers can comply with the rules while bringing innovation and excitement. Design thinking models – rational, clear and comprehensible, give the impression of solving the paradox. They shatter the myth that designers might possess “some mystical, creative thought process that places them above all others” (Norman, 2010).

“Design thinking is a powerful public relations term that changes the way in which design firms are viewed. [...] So, long live the phrase “design thinking”. It will help in the transformation of design from the world of form and style to that of function and structure. It will help spread the word that designers can add value to almost any problem, from healthcare to pollution, business strategy and company organization. When this transformation takes place, the term can be put away to die a natural death.” (Norman, 2010). Including design thinking in companies had a pedagogical effect, enhancing the recognition of creativity. Its tools, now widely known and used, proved useful to accompany ideation and federate multidisciplinary teams. Designers cannot hide behind the “magic of design” any more: they need to clarify their means and ends. But this doesn’t mean that the mystery behind inspiration is unravelled, nor that professional designers are no longer needed. Design thinking is a narrative missing a large part of design activity. It is a myth – a rhetorical figure orienting the understanding (Barthes, 1970). And like any myth, its symbolic and federative values are more important than the far more complex
reality. Exploiting the power of design thinking can help promote design methods, showing that the discipline can help facing any issue, until entering companies’ organization. Yet, there is a risk to absorb it until inhibiting the transformative power of design.

When used as a closed and context-independent methodology, design thinking results at best in incremental innovation (Nussbaum, 2011). This impedes the proposition of new scenarios based on strong and disruptive visions, beyond the problem solving approach theorized in the 1960s. If tools are meant to be transferable, design projects are not carried out in vitro. Design is a whole context-dependant system of knowledge, competencies and know-how (Deserti & Rizzo, 2014). Facing real life complexity, the first skill of designers is to adjust tools and methods on a case-by-case basis, even to design their own. Rather than spreading “good practices”, design expertise develops over time a range of management and creative practices that are specific and situated. Instant insights, creative teamwork, ethnographic observation or transformative visions are as many colours on the palette: basic ingredients that only predict few of the final artwork.

… To the critical heteronomy of design

An organizational shift is needed for companies to make the most of design expertise. Being creative at problem solving is no longer enough, as creativity is the lowest common denominator between all actors of innovation. The challenge now is to carry strong visions based on holistic, yet singular, views. This allows for innovation cultures to value doubt and contingency to spur innovation, combining design strategy with tactics (De Certeau, 1990). In this line, using complexity and paradox as spaces for creation appears wiser than trying to dissolve them into unequivocal processes.

Until now, design thinking tools have been used to feed the how of design, providing methods and techniques. But, as noticed above, design is more concerned with mysteries than with problems, its expertise being more than a set of tools. Designers search for meaning and support the process of change in companies.

This is where design management comes into play, disseminating design in different areas of companies, fine-tuning the articulation between the individual and collective territories (Bobo & Ract, 2008). Inclusive creativity workshops, where consensus reigns, are not fully indicative of design expertise. It takes professional designers to maintain coherence and strength along the project, integrating pieces without losing sight of the big picture. Besides, companies should not reduce design to isolated interventions aiming at launching innovative products or services. Design is a long-term, process-oriented accompaniment addressing companies’ outputs, but also frameworks and people themselves (Michlewshi, 2015). It is an influencing force in the physical sense of the word, not native but “invading the corporate world” (Michlewshi, 2015). In perpetual movement and somewhat on the margins of the industrial, scientific, economic and commercial systems, designers exercise some kind of critical heteronomy (Caraes, 2008) in companies. Design thinking tools and methods being now widely implemented, it may be time to go beyond accompanying discourse (Jeanneret, 2001) and take the risk of opening up to design culture. Or in other words:

“I think future industry needs to revolve around its creative centre, and, through osmosis, take on board vibrations of madness.” (Mendini, 2006)

**Author Biography**

**Estelle Berger**
First trained as a designer, Estelle Berger obtained in 2014 a PhD in Applied Arts for research on the reflective practice of design. Supported by theory and an analysis of design practice in context, her research investigates the singularity of designers and the stances they adopt in companies and society at large. Her scope focuses on ethics, understood as a constant introspection and assessment of designers’ means, positions and ends in professional force fields. As a lecturer at Strate School of Design, she accompanies experience design and cross-disciplinary innovation projects, putting an emphasis on the sensitive and imaginary dimensions. Based on action research, the collaborative projects and activities run within Strate research lab aim at developing a toolbox for professional practice and reflection-in-action. As a designer, Estelle Berger specializes in experience design, with a predilection for the promotion of handicrafts through design.
Creating Different Modes of Existence. Towards an Ontological Ethics of Design

Jamie Brassett, Reader in Philosophy, Design and Innovation, Central Saint Martins, University of the Arts London, UK, j.brassett@csm.arts.ac.uk

Abstract

This paper will address some design concerns relating to philosopher Étienne Souriau’s work Les différents modes d’existence (2009). This has important bearings upon design because, first, this philosophical attitude thinks of designing not as an act of forming objects with identity and meaning, but rather as a process of delivering things that allow for a multiplicity of creative remodulation of our very existences. Secondly, Souriau unpicks the concept of a being existing as a unified identity and redefines existence as a creative act of nonstop production of a variety of modes of existence. In doing this he not only moves ontological considerations to the fore of philosophical discussions away from epistemological ones, but does so in such a way as to align with attitudes to ethics that relate it to ontology – notably the work of Spinoza. (This places Souriau in a philosophical lineage that leads back, for example, to Nietzsche and Whitehead, and forward (from his era) to Deleuze and Guattari.) In thinking both ontology and ethics together, this paper will introduce a different approach to the ethics of design.

Keywords: designing; ethics; instauration; modes of existence; Souriau

I say: each being, in order to exist must discover its mode of existence (or even, have it discovered for them); and emphasise that there are some modes of existence to be discovered still unnamed and unexplored. Without inventing or innovating these modes, we will not be able to establish [instaurer] certain things and they will remain unfulfilled. (Souriau, 2009, p. 161; my translation).

With the proliferation in recent years of the importance of ‘co-’ in designing\(^1\) we might say that the value of ethics to design has increased, whether overtly discussed or not. This would require a particular way of considering ethics, however: as a measure and a delivery of the intensity of the relationships between people. Such an account of ethics is by no means normal and owes much to the works of philosopher Benedict de Spinoza (1996), as well as to others who have been influenced by him, especially Gilles Deleuze and incorporates within it, as a necessary part of ethics, an attitude towards ontology (the study of being). It is the purpose of this paper to bring this attitude towards ethics to design.

As might be expected, the journal Design Philosophy Papers has played a large part in providing design’s ethics a philosophical voice (note especially: Willis (2004), Tonkinwise

\(^1\) For a good overview of some of the main texts in this see Sanders & Stappers (2008) in particular, and the journal CoDesign in which their article is published.
though not exclusively (see also the journals: *Design Issues* – notably d’Anjou (2009) and Taylor (2013) – and *Design and Culture*), and there is a chorus of designers and design researchers for whom an ethical (and related social) conscience is important. Oftentimes, however, positions on ethics are reached by following paths that rather focus upon morality; in particular, approaches to morality which judge good/bad behaviour according to principles that transcend the milieus in which they are implemented. This is especially the case of Viktor Papanek’s influential work on social and ethical design, *Design for the Real World* (1984), which provides a series of imperatives – be authentic not phony, address needs not desires, be good not bad – according to which design should be practised.

Philosopher Gilles Deleuze offers a different approach to ethics, describing it in the shorter of his books on Spinoza (1988, p. 23) as ‘a typology of immanent modes of existence’.

‘Typology’ would appear an odd word for Deleuze to use, as it seems either to draw elements together in relation to common forms or features, or to homogenise via a totalisation of form, both of which approaches run counter to his philosophy. Its use in design might reinforce this, where typology can stand for an ideal form of something (in a Platonic sense), or a unified set of formal codes according to which things (products, images, services and so on) can be designed in order to be understood. Deleuze’s conception, however, is otherwise. As a thoughtful investigation of types, of instances or creative moments, typology in Deleuze’s case can designate an account of the modes of existence created in milieus co-extensive and co-intensive with the typological process itself. Thus, an ethics regarded in this way does not transcend or idealise, neither does it homogenise or totalise, but follows the events in which modes of existence are created and impact each other. For Deleuze, following Spinoza, ethics is thus a deeply ontological concern, as stated above, and delineates a field of relative potentials from which our individual and singular modes of existence emerge as processually dynamic and relationally affective. In this way, our opportunities for being are immanent to the possible relations according to which they could be manifest and ethics is immanent again to all of this not simply as a reactive reflection on such opportunities, but an active creation of them too. This approach entails a redistribution of a simply identified individual across an array of modes of existence, not all of which will be accessed at any one time, and which may

---

2 The work of Tony Fry (2008, 2010, 2012) is important to mention, as it provides a way of thinking the creative relationship between designing and human ontologies, albeit in a way very different to the one I propose here. His (2012) *Becoming Human by Design* states such a programme of thought and action explicitly. He writes that the current condition of uneven consumption relations between human, non-human life and the rest of the world ‘requires that we start to embrace ontological futuring practices from a far more critical and strategic basis, this so as (a) to be able to adequately interpret the emergent experience of the fractured human condition as the status quo implodes under the pressure of an ever-growing defuturing human global population; and (b) to be able to make new modes of agency that are viable, intelligible and efficacious’ (Fry, 2012, p. 37). There is much here that would require a Fry-focussed piece to examine properly: for example, the concepts of futuring and defuturing, as well as the ‘fractured human condition’. Nevertheless, it is worth noting here that while Fry endeavours to deliver an ontological designing that highlights ‘modes of agency’ is not dissimilar to what I propose in this article, his philosophical foundations of Heidegger, Derrida and a way of thinking Nietzsche influenced by both, is markedly different to mine.

3 Notable in this area is the DESIS (Design for Social Innovation and Sustainability) Network (http://www.desis-network.org) and the work of its founder Ezio Manzini (see particularly Manzini 2015). DESIS also has a relationship to philosophy via a series of lectures it curates under the title DESIS Philosophy Talks (http://www.desis-philosophytalks.org).

4 The use of ‘concern’ here, and throughout, follows both Latour (2008) and Whitehead (1966). Whitehead is explicit in using it ‘in the Quaker sense of that term’ (1966, p. 167), which is a (divinely inspired and so
exceed any individual if taken together. This will prove to be an important pair of points, especially when considering designing as an ethical and ontological act.

This paper will make a start on investigating modes of existence in relation to design, and to highlight a way of thinking ethics that arises. (With this in mind, it is clear that many important issues will need to be side-lined for the moment – specifically, those of immanence and of the social forms that emerge from this affective interplay of modes – with the thought that they will serve as the focus of other work.) This discussion of modes of existence will pay particular attention to Étienne Souriau’s *Les différents modes d’existence* (2009), because the reconsideration of Being in terms of creative, multiplicitous and dynamic modes of existence will provide for design the basis for a different way of doing ethics, just as Deleuze states. My argument will posit that in generating (or not) the possibilities for the flourishing of modes of existence, in many different relationships with other modes at different scales, design will necessarily be entangled within concerns that can be recognised as ethical. This paper will address this in two main sections: a ‘Literature Review’ that unpacks the concept of modes of existence, with emphasis upon the role of creativity here; and a ‘Discussion’ section that brings this concept to design, drawing out the ethical issues that arise. Finally, the ‘Conclusion’ will not so much draw a close to this topic, as find directions to take it further.

**Literature Review: on different modes of existence**

In order to focus upon the concept of ‘modes of existence’ that Deleuze announces in the quotation referred to above, and to draw out the elements of this concept that engage with ethics and fold them into a way of thinking and doing design, it is worth noting first that alongside Souriau there are two philosophers with contemporary currency upon whom we can draw to examine modes of existence: Alfred North Whitehead and Gilbert Simondon.5

For Whitehead, to consider modes of existence is already a critical response to ways of thinking ontology that have always only allowed an engagement with subjects and objects. Philosophy seems forever to have sanctioned only these two possibilities, Whitehead bemoans – across his work, and sometimes with real ire in his tone – revolving around them as around a pair of dead stars: one year closer to one, another year the other. This ‘bifurcation of nature’, as he terms it, has rooted in us and rooted us, keeping us constrained in our thinking and bereft of creative endeavour. For him, it is a ‘facile vice’ (Whitehead, 2004, p. vi). Philosophers and scientists might argue over the prominence of one or the importance of the other but, in the end, there are still just the two of them. Whitehead’s work takes us away from this tendency, exploding subjects and objects into new possibilities: multiple experiential and experimental modes of existing, each with their own trajectories of becoming. Subjects and objects become moments in more nebulous ‘occasions of experience’ (Whitehead, 1967, *passim*), whose cloud expands from initial burst, and which is cut across by modes of existing. The dissolution of subject-object bifurcations into constellations of multiple modes of existence offers much to

---

5 There are companion articles to this that focus on various concerns mentioned so far. One centred around Spinoza’s conceptualisation of affect in relation to ethics and social design, is currently under review for a journal. Another on Simondon’s characterisation of modes of existence is almost finished, while others on Whitehead’s ‘bifurcation of nature’ and Deleuze and Guattari’s concept of ‘assemblage’, are works in progress. All of these articles seek to develop an ethics of design based around modes of existence.
For Simondon, the emergence of the individual from its preindividual conditions is neither a totalising nor an exhaustive act. With a nod to one of his thesis advisors, Georges Canguilhem, Simondon (1989, 2005 & 2009) develops positively productive feedback loops from milieu to individual in which the individual’s ontological conditions of creative proliferation are assigned to the simultaneous development of multiplicitous modes of existence (Canguilhem, 2001). This is an extremely entangled, complex situation that demands an investigation of the ethical and material forces according to which modes of existence are designed. Nevertheless, this produces not simple, well-defined and well-identified beings – users and their needs, for example – but teeming, creative, agents always in the process of coming about.

It is probably thanks to Bruno Latour that Souriau is coming back into the philosophical spotlight; as Latour (2011, 2013) has spent some time over the past few years engaging with Souriau’s work, examining modes of existence in particular. Renowned for his work on aesthetics, Souriau’s astonishing Les différents modes d’existence has recently been republished by Presses Universitaires de France (2009) with an extensive introduction co-written by Latour and philosopher of science Isabelle Stengers. Souriau’s work has warranted little discussion over the decades, which is particularly lamented by one thinker who has devoted much to Souriau’s work: Luce de Vitry Maubrey who, in 1985, believed that the time was ripe for Souriau to be remembered. It didn’t quite happen. In an insight obviously ahead of its time, De Vitry Maubrey (1985, p. 327) acknowledges that ‘entering Souriau’s cosmological vision requires a radical revamping of some of the basic assumptions of the traditional way of thinking’. A ‘revamping’ that requires epistemology becoming ontology and finding ‘the empiricism in the transcendental’ (Mikel Dufrenne quoted in De Vitry Maubrey, 1985, p. 327).6

Souriau writes of his ontology that:

It is a matter of inventing (as one ‘invents’ a treasure7), of discovering positive modes of existence, coming to meet us with their palm fronds, to greet our hopes, our aspirations, or our problematic speculations, in order to gather them in and comfort them. All other research is metaphysical famine. (Souriau, 2009, pp. 142–143; my translation).

The greeting, welcoming, opening towards that describes an act of creating, instauration not only the work but also our modes of existence. This instauration – inception, establishment – is an important concept for Souriau as it takes the creative act away from being regarded as

---

6 The currency of the points De Vitry Maubrey (and Dufrenne) make can be recognised especially through the work of philosophers with interest in some of those already mentioned (Deleuze, Whitehead, Simondon), for example: Sauvagnargues (2010), Massumi (2011) and Stengers (2011).

7 The phrase “‘invents’ a treasure” here is a strange one to native English speakers. Latour’s typically playful note describing it (2011, p. 311 n. 30) runs: ‘The French legal term for someone who discovers a treasure is actually the “inventor” . . . . French is constructivist by construction!’
the imposition of form onto inert matter by an energetic genius,\(^8\) and makes of it an act and event at the very heart of being. The urge to create drives all being and without it there would be nothing. For Souriau here, then, being is neither foundational, nor founded on an individual (see also: Simondon, 1989 & 2005), but must be uncovered, discovered, created in continuous moments of ontogenesis; and this is not being as a unified, unchanging mass either, but an ever-changing dynamic of different modes of existence. That is, a plethora of micro-becomings at times coming together, and others fleeing apart (see also: Guattari, 1989). To work as an artist, a philosopher – or even a designer – without engaging in such \textit{instauration} is, he emphasises, ‘metaphysical famine’. In this way creativity allowed by \textit{instauration} and which it congruent with it can bring forth, welcome, open up the possibilities for myriad modes of existence. Stengers and Latour – in their prefatory essay to Souriau’s book – add their own exposition in terms that are heavily reliant upon the examples of creative practice that are so important to Souriau: ‘To say of a work of art that it is “instaurated”, is to prepare oneself to make of the potter one who welcomes, collects, prepares, explores and invents – as one invents a treasure – the form of the work’ (Stengers & Latour, 2009, pp. 10–11; my translation). Being \textit{instaurated}, a work of creativity emerges from an entanglement of different forces – some channelled through the human, others from a multitude of other directions – and allows for the variety of beings that coalesce along the way their own inception.\(^9\) Piece by piece, moment by moment, collision by collision, creative works are discovered and invented by those for whom their very beings are in reciprocal processes of discovery and invention (Souriau, 2009, p. 108–109; my translation). No one artist or potter – or designer or philosopher, or anyone, for that matter – is in control of this process, but finds themselves emerging at the confluence of the forces coming together in/as things.\(^10\) This highlights the important issue concerning the immanence of the thing created and the creator. It is an important point for Souriau that the act of creation opens up ontological opportunities for both creators and created.

For Souriau, to focus upon modes of existence is to recognise that being is multiplicitous, dynamic, changing and creative, more than single, simple and identifiable, and always yet to come – that is, it is in a process of becoming\(^11\). In an essay which brings Souriau’s concept of

---

\(^8\) Hylomorphism is the term given by Aristotle (1986) to giving form to inert matter, particularly in the sense that the soul gives form to the body’s matter. Simondon (2009) rails against this notion, offering instead a creative, morphogenic process whereby matter forms itself. See also: Brassett & O’Reilly (2015), Crawford (2015), Hales (2015) for discussions of these concepts in relation to design.

\(^9\) In \textit{Genesis} (1995, p. 57) Michel Serres explains: ‘instauration is a Greek word meaning fork, meaning bifurcation, which sketches a cross or a dovetail. In the beginning is the crossroads’. The emphasis here is on the break, or change of direction, of a flow. For a questioning note about Serres’s etymology here, see Brassett & O’Reilly (in press) n. 5.

\(^10\) In Chapter 6 of his book on Leibniz and the Baroque that Deleuze (1993) devotes to Whitehead, he gives a marvellous quotation from Leibniz that illustrates just this point: ‘As if the [orchestra’s] instrumentalists played the little phrase far less than they were performing the rites it required in order to appear’ (Deleuze, 1993, p. 80; quoting Leibniz’s ‘Letter to Arnauld’ (April 1687), Mason (1985, p. 119)).

\(^11\) Whitehead (whom Souriau references positively in the work under discussion) shares an approach to being that prioritises its process of becoming rather than its transcendent unity: ‘how an actual entity becomes constitutes what that actual entity is; so that the two descriptions of an actual entity are not independent. Its “being” is constituted by its “becoming”. This is the “principle of process”’ (Whitehead, 1978, p. 23; original emphases). See also Connolly (2011). It is important, also, to note here an important concept in Souriau’s text, one that Stengers and Latour focus
instauration and Simondon’s approach to individuation into collision, Alice Haumont explains that both philosophers ‘build a thought that embraces the modes of existence between which human life is woven’ (Haumont, 2002, p. 70; original emphasis; my translation). Human life is not situated in any special being-human, but erupts in between the creations in which it is implicated and explicated, across many different modes. She writes further: ‘[the human] can become human only on condition of opening itself up to these ways of being that surpass it on all sides’ (Haumont, 2002, p. 70; original emphasis; my translation). The human is the basis for all its possible modes of existence (‘these ways of being’), without being their cause, and if it is ‘opened up’ to them can find many new ways of being. That is, if it can engage in an active and creative becoming it will recognise that all modes of existence are possible and should be welcomed. As Haumont’s human opens up it finds that its own interstitial moments offer opportunities for ontological development. For Souriau it is important to acknowledge this when considering creativity. Thus, creativity is not a transcendent set of rules to which everything must adhere in order to be creative, but a way of existing whose principles for future elaboration emerge from the particular instances of any creative event. (In this way, we can also notice Deleuze’s recognition of the value of immanence to ethics.) Haumont highlights too, following Simondon and Souriau, that the human is not a unifying or totalising factor bringing all these things under control, but the name of a particular set of material and energetic tendencies that assemble and affect each other and the milieus in which they operate. The design consequences of this encounter with modes of existence will be the focus of the discussion that follows.

Discussion: the potential for designing

It is with Latour’s reading (2011, 2013) that many of the design-related issues emerge; though this is not necessarily a novel evaluation of Souriau’s work, interested as Souriau was in aesthetics. As discussed above, Souriau regards the bringing into being of a work of art—or science Latour adds; or, we might add, design—as an act of devotion, an act of instauration that encourages the work on its trajectory of becoming at the same time as it provides the material upon which an artist’s, scientist’s, designer’s, and so on, own modes of being are conceived. Souriau explains:

But one can also exist by the force of others. There are certain things – poems, symphonies or homelands – that do not possess access to existence by themselves. Man has to devote himself to their being; and perhaps in this devotion he might, incidentally, find a real existence. In any case, this act of existence designates and takes note of this success (of being or its support) insofar as it is achieved. (Souriau, 2009, p.

upon heavily: that of the ‘work to come’. I will leave a full examination of this to another time, suffice to say that existence considered as a ‘work to come’ will be oriented externally (as De Landa (2006, 2016) says of assemblages), developing new relations and opportunities for affecting and being affected, forever proliferating its different modes of being as becoming, rather than as an ideal possibility of future unification

12 It is worth remembering the affective and so ethical nature of the original Greek for this term, aisthetikos, which relates to sensation. Souriau gathers this in a marvellous line about things: ‘Sensations are in a way the roar of phenomena’ (Souriau, 2009, p. 117; my translation). For a fuller discussion of the affective import of design’s aisthetikos swerved through the question of the role of style in designing and innovating the future, see Brassett & O’Reilly (2015).
There are things whose participation in existence is mediated and modulated through human creative action, Souriau explains here, while at the same time this action allows for human existential journeys to flow; indeed, these very journeys are engendered by what had seemed like a one-way creative inception from creator to created thing. The success of Souriau’s *instauration* is evident not only in multiplicitous existences that it produces, but as multiplicitous too. The thoroughly intertwined ontological generation of creator and created in any act of creation shifts existential locus from any one mode of being across a whole field of possibility. Just as Spinoza (1996) distributes of ethical import across a network of variously intensive and related elements, so here Souriau undoes any reliance upon actual or transcendent unity of being, favouring instead a collection of modes in ever-churning dynamism. To design things, then, is that process in which the designer devotes her or himself to the possibilities of her or his own being; and the things, the multi-modal opportunities that are *instaurated* in any act of creation, open up at least as many directions for her or his being to become. This is further intensified as the existential modalities offered to those who encounter this work are themselves opened up to new possibilities (or closed down into a straight-jacketed single mode of being). This is probably the most important implication of this study regarding design: that the act of designing can welcome potentially disruptive energetic, creative flows into modes of existing that blossom as much for the designers as for us all. However, it can also shut these down, or restrict all opportunities to those most easily controlled. Here lies the ethical import of designing; to which I will return in the concluding section of this paper.

The ‘roar’ of phenomena giving rise to sensations (Souriau, 2009, p. 113; my translation) is an effect of the multimodal bringing into being undertaken not only by individuals creating things, but also by the multiple and complex web of relations in which their (individuals, things, spaces and all) existence is entailed. Humans’ modes of existence and the works that they produce are in relationships that are either reciprocally supportive or damaging. ‘Each mode [of existence] alone’, Souriau (2009, p. 111; my translation) writes, ‘is itself an art of existence’. It seems irrelevant whether the modes of existence that emerge from the relations between humans, spaces, technologies, things, and so on, belong to any one of those categories (human, spaces, technology, things and so on), so utterly intertwined are they in each other’s existences. And to draw each one, any one, of them out is an art, a skill, a fiction, a fabulation – a design. Any act of designing can allow for, or deny, a range of ontological opportunities simultaneously, at levels that go from the micro- to the macro-modal.

Contemporary smartphones exemplify this well. One does not simply design social systems of smartphones, but ways of being and becoming whose inter-affects allow better or worse relations between a number of assembled modes: human-human, human-thing, thing-social, human-thing-social, and so on. Design theorist Betti Marenko (2015) highlights such qualities in her essay ‘Digital Materiality, Morphogenesis and the Intelligence of the Technodigital Object’. Not a simple object, the smartphone, Marenko posits (2015, p. 107), becomes whatever ‘app, programme, stream of data’ it runs at any moment, converging a ‘highly immersive, sensory and somatic’ set of experiences, becoming ‘a new assemblage of multiple material intelligences, not necessarily and not exclusively human’. For Marenko the liquidity of ontological positions adoptable by such a technological ‘device’ puts into question those of
the ‘humans’ supposedly ‘using’ them. As the materialising and dematerialising nature of the phone remodulates its own existential opportunities in relation to the particular contingencies according to which its software and hardware interact (with, it should be said the various assemblages of power, mapping, locating and control that designate contemporary portable devices), Marenko offers, so it also does for ‘us’. Such a platform – all hardware (Kittler, 1992; see also Marenko, 2015; Hales, 2015, 2016) – is a material space of possible existences modulating and remodulating. The smartphone as morphogenic platform, immersed in an array of intensities from which a range of different modes of existence can coagulate, instaurates in exactly the same way that Souriau shows at the crux of created thing and creator.13

The collision of designed things and the people implicated, and explicated, in their creation (named variously ‘designer’, ‘user’, ‘consumer’ and a whole host of other terms) locates ontogenesis not in simple isolation, but spread across networks of mutually affective modes of existence. While the complexity that characterises the creative relations between all of the different existential modes does not allow for an easily identifiable locus of control of such creativity, it is clear that particular combinations, identifications and relations put into effect by the processes of designing afford specific ontological outcomes. Taking both of these points together, we can say that any particularities afforded by specific design outcomes, the complex and mutually affective relationship structures in which they sit, and the potentials that remain for the further creative remodulation of all of these, highlight that design is working already within ethical concerns.14 Put another way, it is an ethical consideration for design to realise through its acts: that it welcomes (or not) existential opportunities; that it works within, and produces, complex mutually impacting relationships; and, that such relational modes of existence can either stagnate or creatively burgeon.15 For Latour (2011, p. 329) the ‘only worthwhile question (in theology as much as in art and science) concerns what it is good to fabricate’ (original emphasis). This might be the only worthwhile question to ask of designing too: what is it good to fabricate, or to instaurate, to allow to emerge from the many different forces, materials and relations that gather together at any one moment, under specific conditions?

13 At the same time, the providers of digital and physical functionality across such devices (and maybe all ‘smart’ devices) use any particular mode or app to identify and cohere their users into controllable beings. The ‘quantified self’ achieved particularly well through connected, smart, designed things emphasises this point. See, especially, Swan (2013), Grew & Svendsen (2017) and Sanders (2017). See also: Williams (2017) for an article in Financial Times that discusses smartphones in terms of design ethics. It is clear that no one example is simple enough only to evidence what it is supposed to exemplify.

14 It is crucial to recognise that such responsibility does not fall to design alone. It, and the various ontological modes that make it up, operate in networks of power and control that include elements (for example, business entities, political parties, cultural formations) that bear the brunt of ethical (and other) responsibility too.

15 Mention has already been made of Simondon, especially insofar as his work relates to Souriau’s. It is with Simondon (1989 & 2005) that we see this ontology pushed to its limits. For him creative ontology, or ontogenesis, should ensure the possibilities for future existential development, for any system in which all potential is exhausted, or realised, stops being creative and becomes entropic (see also: Brassett, 2005, 2015 & 2016).
**Conclusion**

An account of Latour’s ‘good’, from the perspective of the sort of ontological ethics announced from looking at Souriau, might map and measure the impacts of the relationships of the many modes of existence brought into the open by designing, account for the modes of existence for which there is still potential, as well as find ways for manoeuvring around acts of existential blockage and deliberate disabling of ontological potential.

Furthermore, along with welcoming the ontological opportunities afforded by any design work, such concepts as have been introduced here might help diagram the power relations instantiated in, and the forces of oppression that disavow, the creative becomings of human, things and all. For example, to map the different modes of existence instantiated by smart, connected household goods, and the forces of power and control that direct such formations – notably, the advertising-based business models that drive digitally networked sociality and the drives therein to cathect attention – brings the relational ethics positioned with this ontology into collision with aspects of design politics: particularly those related to design activism (for example: Fuad-Luke, 2009; Julier, 2013a & 2013b), social design and innovation (for example: Gamman & Thorpe, 2011a & 2011b; Manzini, 2014 & 2015), and critical approaches to design’s relations to neoliberal economics (Julier, 2017). In all of these examples of social and economic politics of design, what is missing is the ontological dimension. Further work is needed to piece some of these discussions together. Moreover, the view on design ethics that I have started to give here – affective and wholly entangled with an ontology of multiple, modal becomings – needs to be elucidated further; bringing into account Spinoza and Deleuze. Lastly, as design has changed its own being in recent times, taking into its realm strategy, organisation and business, for example, it would be worth mapping how a discussion of ethically affective, multiple modes of existence can scale up to various sizes of collective depending upon the relative perspective one is taking. Modes of existence can, of course, take shape as, and cut across, organisational strategies, social networks and cultural forms, and so many other things.

It serves to finish, for now, with the assertion that a designing that takes account of the modes of existence that it opens up, promotes or shuts down, at the very least becomes ethical through its ontological focus. It does so not by referencing a transcendent system of ideals or imperatives, but as a creative act deeply entangled with the existences with which it plays – the designer’s own included. It is ‘immanent’ to the creative typologies within which it operates, as Deleuze writes (1988, p. 23; and quoted above). The realisation for and in design, here, is that design is always already ontological, in that it instaurates, modes of existence. This cannot be avoided. The addition via the argument I’ve been presenting, is that the creation of modes of existence is always already ethical too. It will serve us well, next, to wonder what ethically, politically and socially we can become.

**Author Biography**

Jamie Brassett

Jamie Brassett is Reader in Philosophy, Design and Innovation at Central Saint Martins [CSM], where he has worked since 1995 teaching most of its subject provision. He is also Course Leader for MA Innovation Management, running that course since it started in 2008. A philosopher by training (PhD, University of Warwick, UK, 1993), Jamie recently co-edited with Betti Marenko the Deleuze and Design volume for Edinburgh University Press. He is currently working on a philosophy book with Richard Reynolds on Superheroes and Excess for Routledge, as well as articles on smart design, a creative philosophy of anticipation, the ontological ethics of design and uncertain futures. Jamie consults in innovation, management and design research, with particular emphasis upon strategic futures. He holds Fellowships of the Royal Society for the encouragement of the Arts, Manufactures and Commerce, and the Higher Education Academy, and is a Visiting Professor in the Department of Design at Anhalt University of the Applied Sciences, Dessau, Germany. Thanks to: the reviewer whose suggestions helped me refine this paper; Juliette and Rose who helped me when my French let me down; my friends and colleagues for discussions on these topics, notably Lucy Kimbell (University of the Arts London), Betti Marenko (CSM), Cameron Tonkinwise (University New South Wales) and Duncan Fairfax (Goldsmiths). John O’Reilly (CSM) is a fine philosopher, friend and editor. Thanks also to my students on MA Innovation Management, who never stop providing a ‘zest for life’ (Whitehead).
Beyond Forecasting: A Design-inspired Foresight Approach for Preferable Futures

Jorn Buhring, The Hong Kong Polytechnic University, School of Design, Hong Kong, Joern.buehring@polyu.edu.hk
Ilpo Koskinen, The Hong Kong Polytechnic University, School of Design, Hong Kong, ilpo.koskinen@polyu.edu.hk

Abstract

This paper engages with the literature to present different perspectives between forecasting and foresight in strategic design, while drawing insights derived from futures studies that can be applied in form of a design-inspired foresight approach for designers and interdisciplinary innovation teams increasingly called upon to help envisage preferable futures. Demonstrating this process in applied research, relevant examples are drawn from a 2016 Financial Services industry futures study to the year 2030. While the financial services industry exemplifies an ideal case for design-inspired foresight, the aims of this paper are primarily to establish the peculiarities between traditional forecasting applications and a design-inspired foresight visioning approach as strategic design activities for selecting preferable futures. Underlining the contribution of this paper is the value of design futures thinking as a creative and divergent thought process, which has the potential to respond to the much broader organizational reforms needed to sustain in today’s rapidly evolving business environment (Buchanan, 2015; Irmak, 2005; Muratovski, 2016).

strategic design, forecasting, foresight, managing uncertainty, design-inspired foresight, preferable futures

Over the last two decades, the role of design in business has gradually expanded beyond merely creating and communicating better products. Design is now being understood by its totality of activities, and the competencies that span vertically across innovation, product development, market and strategic decision-making, and the capabilities that converge horizontally across interdisciplinary stakeholder teams responsible for creating sustainable value propositions that ensure the organization’s future (Bohemia, Rieple, Liedtka, & Cooper, 2014; Heskett, 2001; Lojacono & Zaccai, 2004). Over the same period, progressive organizations have noted the favourable use of design principles applied to problem-solving, sparking the popularity of design thinking processes and applications toward transformative innovations in a global economy (D. Dunne & Martin, 2006; Oster, 2008). Design principles as strategic tools in the development of an organization’s future-orientation, positioned strategic design as an organizational competence that looked beyond one-time creative outputs (e.g. products or services), toward design as an organizational activity that can lead to sustained innovation and competitiveness (Boztepe, 2016;
Heskett, 2001; Mozota, 1998). Consequently, as design and innovation are becoming increasingly synonymous in both meaning (e.g. Design Thinking) and reach (e.g. products, services, business models, and systems), the priority task of the world’s top management, economic, and educational leaders is to effectively manage knowledge and to generate an innovative and highly adaptable workforce culture.

With creative processes today being applied beyond a given product or service lifecycle, design-led innovation teams are recognizing the forward-looking perspectives of conceptualizing design, in practice and research, as the imagination and creation of possible futures (Grand & Wiedmer, 2010). Indeed, as businesses must learn to navigate disruption, make sense of complexity, and adjust to an uncertain future, the organization’s decision-makers have to prepare for what lies ahead so that the enterprise remains at the cutting edge, while maintaining credibility and leadership (Bevolo & Brand, 2003).

In this context designers have been relying on trend forecasting techniques to interpret social, technological, economic, and environmental drivers that help inform and identify future product propositions formulated in a state of ‘believability’ (Evans, 2003). Equally, interdisciplinary innovation teams practicing design thinking have been empowered to search for breakthrough ideas with the help of user-centred research, behavioural observations, and technology and design road-mapping techniques, to uncovering the unexplored human needs and desires that inform opportunity spaces for innovation (Gabrielli & Zoels, 2003; Meroni, 2008). Beyond the theory and practice of forecasting, however, how can designers and design-led innovation teams really engage with possible futures and go beyond forecasting micro-scale product or service solutions? More pointedly, how can they strategically develop a vision of whole systems futures in a world that could be, by taking varying perspectives - be it an organization desired, the marketplace to come, the industry to be, while considering evolving consumer behaviours and cultural patterns?

**Design Futures**

The design world has created several practices for getting a grip on futures. Some practices are familiar to researchers from other disciplines even though their outward appearance might be different. One premise behind user studies is that by studying existing reality closely enough, designers can then discover things that might contain the seeds of the future. These techniques usually start from ethnography, which is used to open up existing practices to cultural probing which stimulates imagination as a base for accessing design opportunities. Designers have also built versions of natural labs (or in design parlance, “the future is already happening somewhere”) (Manzini & Vezzoli, 2003; Molotch, 1996, p. 257-9), studied street fashion (also sometimes known as cool hunt) (Polhemus, 1994), and studied mobile technologies first in Scandinavia and then in Korea. A variety of this argument lives in studies of extreme users inspired by von Hippel’s notion of lead users (Djajadiningrat, Gaver, & Fres, 2000), in crowdsourcing techniques (Kurvinen, Koskinen, & Battarbee, 2008), and in experience prototyping techniques (Buchena & Suri, 2000). A recent trend in design is propounding fiction as a way to create futures (Bleecker, 2009; Dunne and Raby, 2013).
Some design-world techniques typical to design are farther away from research. One class consists of conceptual techniques like haute couture, concept cars, and electronic prototypes that probe futures in trade shows, expos and design media (A. Dunne & Raby, 2001, 2013). Other conceptual techniques have their origins in utopic architecture that has given architects means for exploring ideas that are currently impossible but yet interesting enough to generate conversations and to prepare for the future (Margolin, 2007). Designers also sometimes borrow from art to explore alternative ways of being by disrupting reality. For example, Martino Gamper’s *If Gio Only Knew* (Miami/Basel in 2007) was a study of imagination hidden in Gio Ponti’s classic pieces of furniture. Out of design disciplines, architecture has had a strong utopian strand. Finally, fashion and textile design build around the notion of trend analysis and focus on capturing and turning trends into bases for design and production (Regan, Kincade, & Sheldon, 1998).

These design-specific techniques have their roots in a variety of design practices that gives them their quiddity. This is also the case in what can be called performative techniques that focus on preparing a future that would be more easily manageable from a design perspective. One technique is design vision (Keinonen, Kokkonen, Piira, & Takala, 2004). For example, *The New Everyday* from Philips Design was meant not so much as a study of the future, but a way to shape expectations in ways that would make design easier (Marzano, 2005). Another class consists of co-branding explorations like *Nothing Happens without a Reason* by Tobias Rehberger and Artek design furniture (2009), a concept café in Venice, which extended the portfolio of Artek and brought free advertisement in media. The final performative technique starts from within the design world, and is exemplified by design projects under Officina Alessi (Marzano, 2003). These projects let Alessi to explore the future through student work (Figure 1).

![Figure 1: Some design foresight technique, clockwise from left: haute couture, concept cars, performance design, co-branding that prepares the futures, and paper architecture](image)

When we look at these practices through future studies, we gain some clarity to how these techniques work. Forecasting is usually defined as an estimation of the unknown (Armstrong,
1985), the predication of time periods before, during, or after the current one (Martino, 1993), and the anticipation of the future based on historical and current knowledge and trends (Coates, 1996). It is useful when data is available and a development or trend can be projected to show changes over time. Under these conditions, trends can be identified with a known likelihood to help inform decisions on what alternatives to the present can be thought of. Through this process, stakeholders in design and innovation can prepare for - or at least envisage the future.

While forecasting is useful when considering the impact of current knowledge projected into a future point in time, a foresight approach is required when challenges and opportunities in the far-distant future cannot be predicted based on knowledge of trends (Gavigan, 2001; Woudhuysen, 1997). Here, the two main attributes of foresight techniques concern the nature of inquiry (qualitative, quantitative or semi-quantitative), and the methods to gather and process information (Butter, Brandes, Keenan, & Popper, 2008). Foresight methodologies use foresight techniques such as macro trend analysis and expert knowledge to explore alternative futures (Figure 2) and classify them into possible, plausible, probable, and preferable (Voros, 2001; Dunne and Raby 2013) present a variation of this model. Foresight methodologies express these in form of futures scenario statements that help prepare for, or indeed actively shape the future, and these methodologies are usually qualitative rather than quantitative in nature (see Cuhls 2003).

When we map existing design world practices into this distinction, we see that most practices are closer to foresight. Maybe this is because forecasting fits better to designers’ self-image as creatives who are called into breaking existing thought patterns. If the defining criteria are a quantifiable estimate of the likelihood of a trend, the only technique that fits in the forecasting category is trend analysis like in textile and fashion design. Due to the structure of these industries, it is possible to capture the future with a reasonable degree of confidence to initiate design processes. In contrast, foresight is needed in volatile high-tech industries in which prediction is difficult and too costly, and the best way forward are creative guesses about the
future. There, at best designers can create visions of the future, and tell which one in their opinion are probable, preferable (designers would talk about utopias), dystopic, and beyond that, merely possible.

Design has many ways to see into the future, but the lack of concise methodological discussion means these techniques do not connect well to future studies. Maybe for this reason, it is difficult to know the limits of current foresight and design techniques (Hines & Zindato, 2016). These limits are, furthermore, implied under the guise of concepts like creativity and radical innovation. These discourses remains obscure for non-designers, many of whom are decision-makers trained in business and engineering. The following pages present an applied research case study of combining a well-known foresight method with design techniques. The study consciously tried to create a mixed methodology that would be understandable and inspiring to designers and non-designers alike. The method used as a basis for foresight was Delphi, a proven foresight technique in the field of futures studies. The study was, however, done in a design school, thus affording opportunities for visualization design, and storytelling techniques to enhance the impact of the study findings.

**Designing design-inspired foresight through Delphi: Financial industry in 2030**

An industry increasingly at risk in dealing with uncertainty, is the Financial Services industry. The Financial services sector is a core pillar of economic activity in most markets, such as greater China (Yulong & Hamnett, 2002), and inherent within are major drivers of change linked to consumer behaviours, new technology, and disruptive business models. Legacy players in financial services are showing signs of losing their competitive edge, while start-up companies (e.g. FinTechs) are using advanced technologies, innovative business models, and value created for a social consumer to disrupt, and fundamentally change the way financial services are being delivered (Chishti & Barberis, 2016).

Consequently, financial services companies not only having to respond to these concurrent changes, they have to prepare for those that are potentially looming in the future. The Financial Services industry, therefore, provides an ideal case for applying foresight in determining futures perspectives; as resent studies suggest, major events or unexpected concurrences of factors are likely to change the global geopolitical or macroeconomic balance over the next 20 years (Pascual-Ramsay, 2015). Not only is the content of what types of foresight methods are relevant to the design research and practice domains, furthermore, lessons can inform the methodological how when engaging research participants in forward thinking toward preferable futures (Bell, 2005).

As introduced earlier, foresight methods can be described by two fundamental attributes, namely by their nature of inquiry (qualitative, quantitative or semi-quantitative), and the capabilities of methods to gather and process information based on evidence, expertise, interaction or creativity (Butter et al., 2008; I. Miles, 2002). To engage in foresight and issue identification, researchers often must rely on the opinions of experts who are better aware of what is going to happen in the future (Rowe & Wright, 2001). Since experts possess tacit knowledge over specific business aspects, they can identify and judge the most critical uncertainties (Linstone & Turoff, 1975).
To identify the major issues through design-inspired foresight, which the organization (Private Bank), the industry (Financial Services), the market (greater China), and indeed consumers (Affluent Chinese) might face in the distant future (2030), a constructivist approach was employed to collect data from a predetermined group of experts with special knowledge in private banking, wealth management, technology, and social science discourse.

Data were collected from these experts engaged in business operations, products and services innovation, and the strategic direction of Private Banking futures using a modified Delphi technique. Delphi is a structured, iterative research process that allows a group of individuals to reflect upon and provide sequential feedback on complex issues while remaining anonymous (Donohoe & Needham, 2009; Linstone & Turoff, 1975). The method is valuable in contexts where experts would otherwise be unable to participate in a study, and has been successfully applied in futures forecasting (Rowe & Wright, 2001).

A three-stage Delphi survey process was developed based on Day and Bobeva’s (2005) “Generic Delphi Toolkit”, where the first stage is an exploratory stage, and further distillation and utilization stages build on the issue categories and themes generated during the first stage to gain deeper, detailed insights and achieve consensus among the experts of what are the preferable futures. Specifically, the objective of the first stage was to gain a broad conceptual understanding of the issues (by issue groups, categories, and their emerging themes) that the financial services providers and relevant experts perceived as challenges, opportunities, and future possibilities. The emphasis was on how each individual expert expressed his/hers understanding of preferable, or indeed, desirable futures.

As a data collection technique, the Delphi is relevant in a design-inspired foresight project where uncertainty over factors that may influence an organization or industry, can be discussed freely amongst a diverse group of topical experts without fear of retribution from their expert peer group (Weber & Ladkin, 2003). The technique itself involves a set of opening questions, which are presented to the Delphi panel through an online (web-enabled) survey tool. Once individual experts have completed their questions, the data is summarized and a set of new questions are designed based on the findings from the first round (Figure 3). This process is then repeated until consensus on the issues presented is reached (Turoff & Hiltz, 1995).
Stage One - Exploration

Planning and preparing for a Delphi survey is perhaps the most important step toward achieving a successful outcome, as the focus is placed on identifying and communicating the main research problem to be addressed. During this stage, the research team has to identify and select expert participants, design and test a data collection tool, develop a series of carefully constructed survey probing questions, and decide on the data analysis framework and method (Day & Bobeva, 2005).

Important consideration should be given to the overall aspiration of the study purpose and objectives. According to Andranovich (1995), the study problem (purpose) and questions posed should match the study participants’ interests in order to ensure meaningful participation. For example, is the inquire intended to be broad: ‘What will the future look like?’, or is the issue under inquiry quite specific to an organizational aspect or hypothetical future? Stakeholders within the organization may have varying motives, be it that some are interested in exploring ways of navigating change and making sense of disruption. For others, the most important outcome is gaining a collective understanding of emerging challenges or opportunities, or uncovering the deeper changes in stakeholder values, behaviours and beliefs.

It is advised that project teams preparing for a design-inspired foresight visioning approach engaging experts as informants of preferable futures, should allow ample time to describe the project aims and objectives, as to articulate the research problem and ensuing questions, and identifying experts needed on the Delphi panel to achieve the overall study outcome (Donohoe & Needham, 2009).
Sampling

Financial service experts were selected with the assistance of a global leader in Private Banking and Wealth Management “Company ABC”. Selecting experts from various disciplines will ensure reliability of opinions, and securing the right expert candidates is an important aspect of conducting a Delphi study. Project teams have to remain resourceful in sourcing panel participants, as there are no certainties that targeted experts are committed to participate in a time-consuming Delphi study. Moreover, the selection process has to remain rigorous and adhere to a set of predetermined selection criterion relevant to the study focus (Linstone & Turoff, 1975).

In this design-inspired foresight study, the selection criterion was determined by obtaining a holistic understanding from experts across functional disciplines that included strategy, innovation, client engagement, product development, Information and Technology Systems (ITS), and Marketing disciplines. To achieve a balanced view from different perspectives, a small group of academic scholars from social science, cultural, and technology backgrounds were invited to join the Delphi panel. The group of experts were engaged via an online data capture tool, which they had selected as the preferred method of communication.

Conceptual Foresight Framework

Questions directed at industry and scholarly experts were framed with the help of a horizon scanning model, which is appropriate in futures studies as the focus is on identifying external trends and developments that may suggest potential implications of early signals of change. Horizon scanning may be defined as “the acquisition and use of information about events, trends and relationships in an organization’s external environment, the knowledge of which would assist decision-makers in planning the organization’s future course of action” (Choo, 2002, p.84). Many horizon scanning models have been developed by those practicing foresight (Talwar, 2010). Their commonalities, however, are scanning, analysing, and synthetizing stages as central components of a model framework. As Curry and Hodgesn (2008) suggest, the “Three Horizons” model enables diverse futures and strategic methods to be integrated to systems and structures, and connected to different speeds of change as applicable (Figure 4).
During the analysis stages, project teams can, as the schematic depicts, identify potential transition points based on their likely disruptive or incremental innovation tendencies. As such, the 1st Horizon focuses the conversation on the prevailing systems (business as usual); it has high strategic fit to the organization’s mission, however, over time it loses its purpose as external forces or factors come into play. The 3rd Horizon, conversely, deals with weak signals, options or arguments about the future of systems that may have consequences to the present environment as it is known. In-between these two horizons is the space (2nd Horizon) where the transition from the known to the unknown (or untested) occurs, and where systems are typically unstable. The time distance between horizons depends on the industry domain or nature of inquiry; the third horizon often requires that systems can be allowed to change significantly (Sharpe & Hodgson, 2006).

Important for research teams who employ the horizon scanning model in a design-inspired foresight visioning approach, is that the 3rd Horizon perspective is deeply informed by worldviews and the values in which the individual expresses his/her opinions. It is here were expert informants exercise their power of voice and experiment, which Inayatullah (2004) suggests makes the “Three Horizon” model such a useful tool as alternative scenarios are informed by different worldviews and logic. In a long-range (e.g. 10 - 15 years) futures study, it is therefore plausible that experts are no longer constrained by their current views of organizational bias, thus expressing their deep-founded believes and values that inform a desirable organization in context of preferable futures.

**Stage Two - Distillation**

During the second Delphi stage (distillation), a group of 12 high-calibre private banking services experts and scholars were presented with a sequence of three major open ended questions. A key objective was to identify the issues that experts considered might impact the organization, the
industry, the market, and affluent consumers in 2020, and 2030. For example, opening the Delphi survey (Round 1), the expert panel was asked to respond to the following question:

1. When considering each of these four perspectives, what are the early signs that will potentially change the way and future (2020 and 2030) of private banking?
   a) the organization,
   b) the market,
   c) the industry,
   d) the Chinese consumer.

For each of the questions presented, experts were asked to nominate at least one issue, and provide their rational for each issue pertaining the four perspectives to the year 2020, and 2030. As a result, in this question example, a minimum of eight nominated issues were anticipated to emerge for each expert enrolled in the Delphi.

The focus of the data collection phase in a Delphi survey is on developing group consensus about preferable (desirable) futures; which in this study, was predominantly focused on the futures of Private Banking to the year 2030. This study involved a serious of two rounds, which were conducted over a period of four months. At the completion of the first round, a content analysis was conducted on the data obtained from the experts, and a total of 237 nominated issues were extracted. As a first step in data reduction, issues were identified, and the rational offered by the experts for their individual opinions were coded and further sorted across each of the four aforementioned perspectives (M. B. Miles & Huberman, 1994).

Four primary issue clusters emerged, comprising of 8 unique issue groups, and 25 issue sub-groups. Standing out were 8 dominant sub-issue groups. Table 1 shows the data analyses findings, where the data reduction process is presented from right to left.

During the data analysis stage, close consideration as to whether or not further opinion-seeking Delphi rounds were needed to reach consensus among the experts, are critical steps in the distillation stage. For this study, the focus was placed on generating scenario statements, which were developed as a synthesis; a method of qualitative content analysis designed to explore issues at a deeper level (Minichiello, Aroni, Timewell, & Alexander, 1990), thereby presenting panel participants with an expression of an idea derived from their combined responses in subsequent Delphi rounds. This data analysis process produced a series of scenario statements across the four perspectives (organization, industry, market, and consumer) that captured the combined opinions in synthesis. In the second round of the Delphi, the likelihood of occurrence rating, and the mean value of the group’s consensus on the scenario statement (Figure 5) were designed as consensus-reaching indicators.
Stage Three – Utilization

From the analysis of data obtained at the completion of the Delphi survey, a summary report was issued to those participants that had completed all Delphi survey rounds, or they had expressed an interest in the final outcomes of this futures study. In this third stage, designers adopting a design-inspired foresight visioning approach have further opportunities to apply data visualization and storytelling techniques. The data visualizations in this study were presented in form of “cloud-tags” and “tree-maps” charting types (Figure 6), conveying important issue clusters, groups, and sub-groups, and their related themes obtained over two distinct time horizons (2020, 2030). The motivation behind this approach was to engage, at a later stage, design-led innovation teams with the Delphi survey findings, consequently channelling the discussions and ideation efforts toward specific outcomes that the data collection and analysis phase of a design-inspired foresight study would produce.
Farther, utilizing storytelling narratives and imaginary creations, serves as an effective way to engage with the intended readership of a design-inspired foresight study in both entertaining, informing, and energizing ways. Stories can change or enhance readers’ perceptions of futures, seeing themselves in different perspectives, and identifying their “self” by interpreting and completing the story in his or her head (Sametz & Maydoney, 2003). In this 2030 futures study, personas were created that embodied the essence of futures scenario statements in verbal and non-verbal communications intended to connect the reader on both analytical and emotional levels (Figure 7).
Milestones toward preferable futures: Backcasting

At the conclusion of the three-stage Delphi survey, and the data analysis and reporting stages of a design-inspired foresight visioning study, design and innovation teams have the opportunity to transform the knowledge and insights gained into a preferred futures conceptualization and prototyping plan. With foresight perspectives generated over 5, 10, or even 15-year intervals, design teams can use a ‘backcasting’ process (Figure 8) to break down preferable (or desirable)
futures scenarios, and, by developing strategies and milestones, plan for how these futures may be attained (Vergragt & Quist, 2011).

![Diagram of backcasting a preferred future to the present](image)

**Discussion**

This paper has introduced a design-inspired foresight visioning approach as an emerging activity within design-led innovation and strategic design processes. Looking beyond forecasting, which creates scenarios of futures using historical and current data and builds trends to develop products or services solutions, the emphasis in this paper was placed on foresight in design as the imagination and creation of desirable futures scenarios. By way of example, a design-inspired foresight approach was presented based on a 2016 Delphi study exploring Private Banking industry futures to the year 2030.

Important considerations and the inherent gaps in conventional methodologies in forecasting were addressed through the deployment of a design-inspired foresight approach. With this paper, a further aim was to demonstrate the expanding role of design in foresight toward the design teams and organizations’ readiness and ability to deal with systemic uncertainties in today’s business environment. Indeed, as the role of design in business is expanding across all aspects of innovation, design-inspired foresight activities aspire to include visualization and prototypes of alternative possibilities that help organizations in their strategic innovation decision-making processes. In other words, foresight techniques are applied to inform the strategic innovation direction, which has the potential to shape the organizations’ future (Mankoff, Rode, & Faste, 2013).
Beyond the traditional organizational practices of predicting the future based on (usually linear) historical and current data, this paper introduced selected methods, techniques, and tools which were applied to envisage organizational, industry, market and consumer perspectives of preferable, or indeed desirable futures in the Private Banking sector. As seasoned practitioners in foresight acknowledge, whichever methodology or method may be applied to futures studies, challenges remain to connect the present with preferable futures in ways that “…helps to identify the divergent futures, which may emerge as a result of conflict between the embedded present and these imagined futures” (Curry & Hodgson, 2008, p.2).

While acknowledging that there are many methods in conducting design foresight, as highlighted in this paper, the value of a design-inspired futures approach is based on the strategic use of exploring alternative futures scenarios. Based on these preferable (or desirable) visions of alternative futures, designers and interdisciplinary innovation teams may further emphasize these future directions through data visualization and storytelling techniques. From this position, designers and business stakeholders can work together to develop innovation strategies, and apply, for example, a backcasting process to determine the physical feasibility of a particular preferred or desirable future scenario. Unpacking each scenario into milestones and prototyping briefs, designers can further apply their skills to help visualize, or indeed demonstrate concepts toward preferable futures.

In this context, the paper contributes to theoretical and practical knowledge in applying foresight approaches linked to design, while offering designers, researchers, and foresight practitioners practical examples of employing, or adapting existing foresight methods such as the Delphi technique, the “Three Horizons” model, and futures scenarios as further inputs for design-led innovations.

Dr Jorn Buhring is a Research Assistant Professor at The Hong Kong Polytechnic University - School of Design; his research focus is on human-centred value innovation with emphasis on user engagement in experiential environments. Addressing future perspectives, Jorn explores design foresight, vision and fiction approaches and techniques aimed at designers and interdisciplinary innovation teams. The aim is to advance emerging design and innovation processes in business through change-provoking futures thinking, and testing these through quantifiable demonstration and applied research initiatives.

Dr Ilpo Koskinen has been working as professor in design schools in Helsinki, Aarhus, Melbourne, and Hong Kong. His main research interests have been mobile multimedia, design in cities, and the methodology of design research. His recent work expands his earlier work on constructive design research into social design. His mission is to use research to expand the methods and conceptual horizons of design from within the discipline.
Participatory Design for Behaviour Change: An Integrative Approach to Healthcare Quality Improvement

Fernando Carvalho, Loughborough Design School, Loughborough, UK, f.carvalho@lboro.ac.uk
Gyuchan Thomas Jun, Loughborough Design School, Loughborough, UK, g.jun@lboro.ac.uk
Val Mitchell, Loughborough Design School, Loughborough, UK, v.a.mitchell@lboro.ac.uk

Abstract

Behaviour insights have been extensively applied to public policy and service design. The potential for an expanded use of behaviour change to healthcare quality improvement has been underlined in the England’s National Health Service Five-Year Forward View report, in which staff behaviour is connected to the quality of care delivered to patients and better clinical practice (NHS, 2014). Improving the quality of healthcare service delivery involves adopting improvement cycles that are conducted by multiple agents through systematic processes of change and evaluation (Scoville et al., 2016). Despite the recognition that some of the recurring challenges to improve healthcare services are behavioural in essence, there is insufficient evidence about how behavioural insights can be successfully applied to quality improvement in healthcare. Simultaneously, the discussion on how to better engage participants in intervention design, and how to better enable participation are not seen as fundamental components of behaviour change frameworks. This paper presents an integrative approach, stemming from comprehensive literature review and an ongoing case study, in which participatory design is used as the conduit to activate stakeholder engagement in the application of a behaviour change framework, aiming to improve the processes of diagnosing and managing urinary tract infection in the emergency department of a hospital in England. Preliminary findings show positive results regarding the combined use of participatory design and behaviour change tools in the development of a shared-vision of the challenges in question, and the collaborative establishment of priorities of action, potential solution routes and evaluation strategies.

Keywords: Participatory Design, Behaviour Change, Behaviour Change Wheel, Quality Improvement, Healthcare, National Health Service

Traditionally, quality improvement approaches utilised in healthcare have been adapted from fields such as industrial management and organisational management which focus on process issues, such as production quality control (Boaden et al., 2008). More recently, human factors and ergonomics, which focuses on understanding interactions among humans and other elements of a system and optimising human well-being and overall system performance, has also been proposed to be integrated to quality improvement approaches (Hignett et al., 2015).
In order to improve quality in healthcare, process issues, interaction issues and system issues need to be appropriately addressed, but there is a growing recognition that some of the recurring challenges to improve healthcare services are behavioural in essence. There is also insufficient evidence about how behavioural insights can be successfully applied to quality improvement in healthcare. This paper aims to investigate how a behavioural approach can be employed to healthcare quality improvement in a participatory way. The first section of the paper will introduce background information in three areas: quality improvement, behaviour change, and participatory design – in order to build a participatory framework for behaviour change for healthcare quality improvement. The applicability of this framework will be tested in a clinical practice improvement project (diagnosis and management of urinary tract infection at an emergency department). Using the framework, the behavioural nature of this issue will be explored and interventions for behaviour change will be developed in a participatory way.

**Literature Review**

**Quality Improvement in Healthcare**

Quality improvement in healthcare encompasses the combined and continuous efforts of patients, professionals, researchers, organisations, and society in the change processes that result in better patient outcomes, better system performance, and better professional development (Batalden and Davidoff, 2007). In essence, quality improvement articulates a “combination of a ‘change’ (improvement) and a ‘method’ (an approach with appropriate tools), while paying attention to the context, in order to achieve better outcomes” (The Health Foundation, 2013), as represented in Figure 1.

![Figure 1: How Quality Improvement is Achieved.](image)

In a review of methods to improve the quality of healthcare (including Lean, Six Sigma, Statistical Process Control, Plan-Do-Study-Act), Boaden et al. concluded that “from a research evidence viewpoint, none of the approaches stands out as being more successful in healthcare than any of the others.” (2008). The publication asserts that “the process of improvement is more important than the specific approach or method” and “the main issue is the way in which the improvement is implemented, rather than the nature of the improvement itself” (Ibid). This emphasis on process over method is supported by the Health Foundation (2013), and Frankel
et al. (2017); they both add that QI projects need to involve a variety of stakeholders to be effective and sustainable.

Dixon-Woods et al. (2012) have identified ten major challenges to healthcare quality improvement projects which can be clustered into three groups: (1) design and planning; (2) organisational and institutional contexts, professions and leadership; and (3) sustainability, spread and unintended consequences. Among the ten challenges described by these authors, many (i.e. convincing people that there is a problem; convincing people that the solution chosen is the right one; the organisational context, culture and capacities; and tribalism and lack of staff engagement) could be directly affected by a change in methodology – e.g. by emphasising behaviour change, stakeholder engagement, and the participatory aspects of how quality improvement approaches are employed.

A participatory behaviour change approach appears especially appealing when we recognise how challenging it is for healthcare organisations to provide services that are safe, reliable and effective at the system-level – i.e., as a continuous ‘culture’ that permeates several departments and engage multiple people within the organisations (Frankel et al., 2017). Behaviour change approaches to QI seem thus very fit, since “quality will only improve where the behaviour of individuals within the system changes and this has to date often been ignored or underplayed in quality improvement efforts.” (Boaden et al., 2008).

**Behaviour Change**

The field of behaviour change is concerned with describing and understanding the causes and consequences of behaviour as to enable changes for the better. A definition that accounts for both individual and contextual factors influencing behaviour states that ‘human behaviour is defined as the product of individual or collective human actions, seen within and influenced by their structural, social and economic context’ (NICE, 2007).

The practical processes of implementing change usually involve some type of planned intervention which frequently relies on the use of behaviour change frameworks. A framework for changing behaviour is fundamentally a game-plan that follows a logic sequence of interconnected stages. Thus, a behaviour change intervention is an activity (or a series of activities) which principal intention is ‘to get an individual or a population to behave differently from how s/he or they would have acted without such an action’ (Michie et al., 2014). Interventions attempt to influence behaviour by applying the appropriate theoretical knowledge and practical expertise, mostly drawn from the many behavioural sciences and related disciplines (House of Lords, 2011).

Using behaviour change interventions as a method for improving quality in healthcare service delivery is a promising strategy that has already shown significant results in areas such as antibiotics prescription, reducing missed appointments, increasing medicine adherence (Hallsworth et al., 2016), optimising referrals, and improving hand hygiene (Perry et al., 2015).
Behaviour Change Wheel Framework

The Behaviour Change Wheel (BCW) is a framework targeted at healthcare practice and public health that was developed from a systematic analysis of other nineteen selected frameworks, built intentionally to overcome their flaws and limitations (Michie et al., 2011). The framework is recognised as being comprehensive and conceptually coherent (Perry et al., 2015); and also as an approach that proposes to “mediate the middle ground between the individual agency and contextual approaches” to behaviour change (Niedderer et al., 2014). At the core of this strategy to bridge individual and contextual factors is a dedicated model of behaviour, the COM-B model, which articulates capability (physical and psychological variables), opportunity (social and physical components of the context and environment), and motivation (reactions and plans). The main purpose of this embedded model of behaviour is to simplify the understanding of the determinants that could account for explaining and predicting changes in behavioural patterns, without incurring in oversimplification (Atkins and Michie, 2015).

Another aspect of the BCW that also attempts to address the theory-practice gap by providing mechanisms to connect the two worlds, is the inclusion of seven intervention functions and nine policy categories in its very structure. According to the authors, these are non-overlapping components that build from the analysis of previous works and relevant literature, and they should assist designers and practitioners in envisioning and planning effective interventions (Michie et al., 2011).

The application of the BCW framework starts from an analysis of the sources of behaviour, using the COM-B model to identify which determinants are causing the occurrence of the behaviour(s) to be changed. Once the behaviour is understood in context, since “behaviours are a part of a system, they do not occur in isolation” (Michie et al., 2014), one or more of the nine intervention functions can be chosen along with the policy category(ies) suitable to deliver the intervention (Figure 2).
The correct use of the framework is supported by eight worksheets that help practitioners to follow the logic steps of the intervention process, considering the necessary variables, and employing the appropriate tools. Amongst these tools is the Theoretical Domains Framework (TDF) – which is “a synthesis of constructs from behaviour change theories, developed in a consensus process to make theories more accessible for implementation” (Michie et al., 2014). The TDF establishes categories of determinants (such as knowledge, social influences, intentions) that can be used to determine which behaviour change techniques are more appropriate to enable the desired changes in the target population. Behaviour change techniques (BCTs) are also key to the application of the Behaviour Change Wheel. BCTs are the smallest components of an intervention that still retain the ‘active ingredients’ that are necessary to enable changes to specific determinants, considering a particular target population and context (Michie and Johnston, 2012). To be effective, change techniques need to: (1) target a specific determinant that predicts the behaviour in question, (2) be able to change that determinant, and (3) be translated into a practical application that works for the target population, within the social and physical environment they interact (Kok et al., 2015).

From a behavioural perspective, the Behaviour Change Wheel is robust and encompassing: it establishes clear relationships between the determinants of behaviour (both individual and environmental/contextual), potential strategies (intervention functions and policy categories), and techniques for change in a stepwise implementation programme. However, like most frameworks, it fails to explicitly incorporate participatory strategies to engage the relevant users and implementers in a coordinated effort for enacting collaborative change.

Problems with Current Behaviour Change Approaches

If we are to look prospectively to employing behaviour change in healthcare quality improvement, we ought to pay attention to some problematic issues about how current frameworks and approaches operate. In the concluding remarks of a recent publication, three main challenges for the future of behaviour change are outlined: (1) the relative disregard for social and cultural factors that influence human behaviour; (2) the need for a transdisciplinary perspective to understand behaviour and change processes; and (3) the ‘evidence conundrum’, embodied in the supremacy of quantitative evidence from randomised controlled trials, which undermine the important scientific contribution of alternative approaches (Spotswood and Marsh, 2016). Concurrently, various problems in applying behaviour change theories to behaviour change practice have been identified in recent years: inappropriate use of theoretical grounding in practical applications (Davies et al., 2010; Michie et al., 2015); insufficient representation of behaviour change expertise (NHS, 2014); and the need for a more multidisciplinary, collaborative approach (Solomon, 2005).

The ‘evidence conundrum’ is an unintended consequence of a growing concern to try and ensure that behaviour change interventions are ‘evidence-based’ and ‘theory-based’. Such approach overemphasises a ‘hard science’, expert-focused view, dominated by strict rules.
ascertained, for example, by the rising adoption of templates for reporting interventions – an excessively rigid perspective that has encountered little open criticism to date (Ogden, 2016).

In this quest to strengthen the body of theory supporting behaviour change, research designs that favour quantitative evidence with much less emphasis on the processual aspects of intervention development have flourished, dwarfing qualitative research approaches that can offer important complementary perspectives. One of the aspects that suffered from this dominating research ethos is the core importance of stakeholder participation, and how the views and voices of those impacted by the interventions should be integrated into the design and implementation of such interventions.

An emphasis on participatory design as a strategy for engagement in behaviour change interventions can address two of the challenges identified by Spotswood and Marsh (year): the ‘evidence conundrum’ (the overstated impact of quantitative evidence and research methods in behaviour change study and practice); and a more transdisciplinary approach to behaviour change (by providing a different philosophical perspective, as well as specific methods and tools). Therefore, we believe participatory design has a major potential to unite with behaviour change, presenting efficient and inclusive methods for quality improvement in healthcare service delivery, as represented in Figure 3.

![Figure 3: Behaviour Change and Participatory Design as the Combined Methods to Achieve Quality Improvement.](image)

**Participatory Design**

The core aspiration of participatory design is to enable the involvement of relevant stakeholder groups in all stages of the design process, including the co-definition of problems, co-development of alternatives, and co-implementation of solutions (Robertson and Simonsen, 2012, 2013). That encompasses the engagement of people in determining technical and social objectives for the design effort, analysing the current situation and problems in question, developing solution and implementation strategies, considering evaluation criteria (Gregory, 2003), and collectively reflecting on the processes of change (Ostergaard et al., 2016).

This overarching aspiration for active involvement is driven by three defining values: having a
say; mutual learning; and co-realisation. As established by Bratteteig et al. (2013), and Robertson and Simonsen (2013), having a say refers to the ability of people to impact decision-making processes with regards to their perspectives of the issues and their vision for the future; mutual learning enables a deep experience of exchange between participants, recognising that all involved have things to contribute with and to get from the collaborative effort; and co-realisation relates to the dynamic of making the changes together, building on complementary strengths and different types of expertise.

To activate these values and put its aspirations to practice, participatory design has combined and perfected a set of methods and tools which assist in the realisation of participatory projects. These methods can be organised into three encompassing categories: methods for telling stories; methods for making things; and methods for enacting possible futures (Brandt et al., 2013). This categorisation expands on a previous work that clustered co-design tools and techniques into three groups: talking, telling and explaining; making tangible things; and acting, enacting and playing (Sanders et al., 2010).

The fundamental point enlightened by these ways of looking at methods and tools is to foster a mindset in which participation permeates the intervention process as a whole: at first, by contributing to better define the problem-space, via enabling the description and visualization of multiple perspectives and contributing factors; secondly, by giving support to activities that explore the solution-space through an experimental process of modelling and prototyping in two- and three-dimensional forms, and in conceptual and concrete ways; and finally, the combination of these two efforts make it possible for future visions to develop as the result of the collective and collaborative engagement of all involved – these visions simultaneously articulate the technological and social requirements needed to put solutions to practice in real-life.

**Framework Development: Integrating participatory design with behaviour change**

The tendency to overlook the participatory dimensions of behaviour change interventions confronts the fundamental, moral and practical importance of improving the participatory aspects of healthcare service in general (Cahill, 1998; NHS, 1998; Crawford et al., 2002; Ridley and Jones, 2002; Guttmacher et al., 2010; Israel et al., 2013; NHS, 2013; Richards et al., 2013), and of behaviour change interventions in particular (Darnton, 2008; Craig et al., 2014). That becomes clear on the lack of explicit reference to participation in most existing behaviour change frameworks. This issue is aggravated by the lack of awareness of many behaviour science researchers about the potential contributions that participatory design could offer: aside from a handful of exceptions (such as Yardley et al., 2015; and Collins, 2016), most published works consulted through our study make no mention to participatory design or co-design approaches and methods to enable stakeholder involvement in behaviour change intervention projects.¹

¹To determine the underlining structure of Behaviour Change Frameworks, we have carried out an initial analysis of ten different frameworks proposed by authors from various backgrounds, across the domain areas of public policy, health, and sustainability. The selected frameworks cover a period from the late 1990’s, when frameworks
One of our primary aims with the present study is to investigate issues related to stakeholder involvement in behaviour change interventions; consequently, a ‘participatory agenda’ guides the work, permeating all stages of the pilot intervention being developed along with the BCW framework. A vital step to accomplishing that aim was to outline a comparison between the stages of the behaviour change wheel framework and the overarching phases of a participatory design process (Table 1).

![Table 1: A Comparison Between the Phases of Participatory Design and the Stages of the Behaviour Change Wheel.](image)

Subsequently, a list of participatory and behaviour change methods and tools could be identified and then paired up with the appropriate stages of the intervention plan. That process allowed for the basis of our participatory approach to behaviour change interventions to emerge, as it is presented below (Table 2):

![Table 2: A Participatory Approach for Stakeholder Engagement in Behaviour Change](image)

began to appear in a more structured fashion, to present time. The criteria for choosing this group of frameworks was through cross-reference in the consulted literature of the field, complemented by a search on digital databases (PubMed, the Cochrane Platform, Google Scholar, and Web of Science). The analysis was focused on understanding how the frameworks outline the stages that comprise the intervention plan, what the objectives of each stage are, and (if reported) the methods employed to achieve the particular goals of each stage and the overall goals of the intervention.
Pilot Study: Testing the Framework

Context

Urinary Tract Infection (UTI) diagnose, especially in older patients that present asymptomatic bacteriuria and confounding symptoms, is less precise and this population is frequently mistreated with antibiotics (NICE, 2015). The situation gets more aggravated since older patients frequently are not correctly assessed due to lack of specific knowledge about this cohort among physicians without specific geriatric training (Gladman et al., 2016). Antimicrobial Resistance (AMR) is a global public health concern caused mainly by “the systematic misuse and overuse of drugs in human medicine and food production” (WHO, 2015), and it has been observed in all regions of the world. Studies carried out in five different countries in Europe and the UK (Tonkin-Crine et al., 2011) and in Ireland (Cullinan et al., 2014) show a broad range of reasons to explain why over-prescription is a recurrent behaviour, even when clinical judgement and scientific evidence suggest alternative approaches.

In the Emergency Department of the NHS hospital where our pilot study is taking place, the diagnostic and management processes of urinary tract infection (UTI) are characterised by several challenging factors, as reported by some staff and observed by the researchers. These involve two major areas of concern which are often in conflict: (1) the current, culturally established practices carried out by ED staff – which, for many reasons, are not always in line with the national ‘guidelines’ or standardised recommendations for ‘best practice’; and (2) the external factors (resources) and pressures (from the organisation and the system, and from users – patients, carers, family) – that make up for the social and professional environment in which decisions are made, and the healthcare services are delivered. Regarding quality improvement interventions, the healthcare context is regarded as distinct and more complex (Boaden et al., 2008), and changing clinical practice is considered particularly difficult to achieve (Dixon, IN: Nesta, 2016).

Participants

The pilot study involves two complementary groups of stakeholders (Table 3) that were purposefully sampled considering their professional expertise; participation in the activities of relevant hospital wards; and their previous knowledge about the importance of addressing UTI in secondary care.

The core group of stakeholders (core group from now on) includes doctors, pharmacists, microbiologists, healthcare researchers, and nurses, totalling nineteen people. The second group of stakeholders (ED group from now on) constitutes Emergency Department consultants working as doctors, nurses, and managers, totalling twenty-eight professionals. The ED group has supported and advised the core group, and acted as liaison agents within the Emergency Department extended work community. Participants’ engagement through the study has been characterised by a diverse (regarding professional profiles) and irregular (regarding number of participants) attendance to in-person activities, and by a continuous process of information exchange and update via digital media (email, text message, and WhatsApp).
Table 3: Pilot Study Participants by Sub-Group and Expertise (with number of male and female participants).

Methods

Our participatory approach includes focus group activities, involving representatives of both groups of stakeholders, as well as meetings, semi-structured interviews, and constant exchange of information via varied means of communication; a diagram of the completed, in-progress and planned activities is displayed in Figure 4 below.

![Figure 4: Activities per Stage of the Ongoing Pilot Study, Following the Participatory Design and the Behaviour Change Wheel Combined Approach.](image-url)
The first activity involving the core group consisted of a workshop in which card-sorting (Kensing et al., 1996; Sanders et al., 2010), user-journeys (adapted as a ‘care journey’) (Hanington and Martin, 2012), and group discussion methods (Aldersey-Williams et al., 1999) were employed to make collective sense of a large volume of findings stemming from in-depth interviews with ED staff.

Our study combines behaviour change and design approaches via an integrative approach. As noted, both the behaviour change wheel framework and the participatory design approach can be described as three-staged processes with many overlapping connections regarding their aims and objectives. In the first stage, the central concern of the BCW is to determine what is the behaviour that needs to be changed – that is accomplished by identifying what is the behaviour, who performs it and with whom, and where and how frequently it occurs. The co-definition phase of PD aims to provide a comprehensive description of the problem-space, considering the perspectives, priorities and concerns of the multiple stakeholders involved. At the second stage, both the BCW and PD intend to explore the solution-space: the former via the identification of suitable intervention functions and policy categories that relate to the specific determinants of behaviour which can predict positive changes; the latter via investigating alternatives in light of appropriate technologies, processes, products, services, that can respond to the current problems through the adoption of new ways of doing and interacting with the physical and social surrounding. In the third and final stage, the BCW explores what change techniques and modes of delivery (means and technologies) are implementable, considering the APEASE criteria to guide appropriate choices (Affordability, Practicability, Effectiveness and Cost-Effectiveness, Acceptability, Side-Effects/Safety, Equity); correspondently, PD considers the ways in which solutions can be collaboratively implemented, tested and adjusted according to the shared-vision of the stakeholders impacted by the proposed innovations.

Findings

Developing a Shared Understanding

From the first stakeholder workshop, a total of one-hundred and thirty-six statements gathered from staff in interviews were converted into prompt cards to be analysed by the group. Participants, divided into two teams, sifted through the cards selecting and ordering those they found to be more relevant considering their impact on clinical practice. The selected cards were then plotted into care journey maps prepared by the researchers in an attempt to connect the suboptimal behaviours of specific professional groups (i.e. doctors, nurses, health care assistants, laboratorians), to particular points in time (admission, symptoms, actions/resources, diagnostic, treatment, discharge).

The workshop finished with a group discussion about the activities in which participants could reflect on their different perspectives and results. These differences were mainly because of

---

2 In a previous qualitative study, O’Kelly et al. (2016) conducted interviews with twenty-one staff from ED at the same hospital (among HCAs, nurses, and doctors from all grades) to identify issues around UTI diagnosis and management. The findings were grouped into six themes regarding Dip Stick testing (why test; who to test; indirect pressures; interpretation of tests; guidelines; and NHS culture and system pressures). The issues identified in the interviews with staff were the basis of the first activities involving the core stakeholder group.
their varied expertise and understanding of Urinary Tract Infection, also because, due to the overwhelming number of findings to make sense of, the two groups had to analyse different sets of statements. The reflective discussion worked primarily to establish a common knowledge base regarding the challenges of diagnosing and treating UTI in the ED department, also helping to establish group cohesion for future activities, since many participants had never worked together before the workshop.

From the analysis of the results of the first workshop, an adapted thematic networks map (Attride-Stirling, 2001) was assembled by the researchers, as an effort to depict a concise visual representation of the many, complex variables which constitute the problem-space. This map was the primary tool used in the second workshop, which had as its main objective to determine a sound list of behavioural challenges: as indicated by the Behaviour Change Wheel framework, challenges need to be framed in terms of who performs the behaviour and with whom, where they do it, when and how frequently they do it (Worksheet 01 – Michie et al., 2014, p.240).

**Identifying/Prioritising Behavioural Challenges**

The thematic networks map was presented to the group and the participants were invited to revise the map by changing, adding or subtracting information from it. With the resulting, revised map, twelve behavioural challenges were identified and listed. The resulting list of challenges was the product of participatory processes that took into consideration a plethora of issues initially identified through interviews with diverse ED staff, that were then discussed, analysed and organised by expert stakeholders, and finally condensed in a manageable number of challenges that can be acted upon through future interventions. The next step was to establish priorities of action, so that specific solutions can be collectively envisioned and developed.

The prioritisation process took place in two stages: the first involved the core group of stakeholders through an online voting system in which participants ranked how much they thought each of the behavioural issues listed directly impacted three distinct dimensions of care: the care provided to patients; the work practice of staff; and the health system in broader terms. The second prioritisation exercise involved the ED group and was done on-site, on a fifteen-minute voting activity, during a senior staff weekly meeting. Participants were asked to individually select their first and second priorities, from the same list of twelve challenges used by the core group of stakeholders.

**Planning Interventions**

The analysis of the prioritisation exercises conducted with both groups showed similarities and slight differences in the top priorities defined by each group. The adopted strategy to deal with these different results focused on a solution that embraces the complementary roles performed by each group of stakeholders as a strength to be explored. Per this perspective, each group can work within their established priorities in a complementary coordinated effort. The core group will focus on behaviour change interventions to impact care at the higher, organisational level; this group is formed by professionals that do not work directly in ED, hence their views on the ward’s day-to-day practice is limited by their lack of practical experience.
The core group’s focus on systemic changes will be complemented by the ED group’s focus on practice-based interventions, according to the priorities established by ED staff. This process has been initiated via the development of interventions with two middle-grade ED doctors that are conducting Quality Improvement projects around UTI diagnosis and management as a requirement for the completion of their medical training. These doctors will utilise behaviour change methodologies, facilitated by the researchers, and collect frequent sets of data on patient outcomes to establish whether the interventions are having short-term, measurable effects in clinical practice. The first step of this process includes the preparation of support materials that will be used by the doctors during hand-over meetings (with other doctors and nurses) in which they will establish a participatory dialogue within the ED. The aim of these discussions will be to adopt a bottom-up approach as to enable ED staff members to devise their own collective solutions for ED care provision.

Conclusion

The findings of this work in progress suggest that it is feasible/potentially effective to employ a behaviour approach to healthcare quality improvement in a participatory ways. Understanding both as three-staged processes with clear alignments and similar goals in each stage will allegedly facilitate their combined application in quality improvement projects. Furthermore, the apparently obvious choice for using methods and tools from participatory design – a field with more than four decades of organised knowledge\(^3\) – in behaviour change projects remains unexplored as a means to address proper stakeholder involvement, and how and by whom behaviour change interventions are planned, designed and implemented.

The advantages of adopting a behaviour change approach to improving UTI diagnosis and management when compared to other quality improvement methods is not explored in this study, which is certainly a limitation. A review of the literature showed that behaviour is a component of many challenges in healthcare service provision and that the use of behaviour change frameworks has had encouraging results in enhancing patient and service outcomes in certain contexts. Regarding the necessity for some level of expert knowledge, the behaviour change approach is perhaps no different from any other; some of the people implementing the approach need to understand its stages, methods, tools and evaluation processes, as it would be the case with Lean, Six Sigma, PDSA etc.

It is beyond doubt that stakeholder engagement has a definite role when adopting behaviour change as a strategy for quality improvement in healthcare. Participation is repeatedly referred in the literature as a fundamental element of intervention design, and of healthcare improvement more broadly. The current study investigates the direct use of specific participatory design methods and tools in alignment with defined stages of a behaviour change framework combined into an integrative approach. At the very first level, we can assert that Participatory Design and the behaviour change wheel approaches are compatible: it is possible to conduct a synergistic process in which one method provides the behavioural tools whereas the other provides the means for its collaborative application. Though the study is still in

\(^3\) If we adopt as a milestone the 1971 conference of the Design Research Society which had Design Participation as its core theme.
development, our participatory approach for stakeholder engagement in behaviour change interventions (Table 2) outlines the logic that will guide the subsequent stages, describing specific tools that can be utilised in each stage of the intervention. The Behaviour Change Wheel tools have been undergoing significant adaptations through the study regarding their format and appearance, as to be more suitable for collective, participatory use (since their current design is clearly intended for desktop, individual use). This adaptation process is indicative of the necessity to better integrate the specific tools of the two complementary approaches explored in this study, a topic that will be further examined in upcoming publications.

Bratteteig and Wagner (2016) have recently published a paper in which Participatory Design is discussed mainly with regards to the evaluation of its results. Their paper’s core contribution lays in the way it connects participatory process with participatory outcomes, perhaps in an unprecedented way. Among the indicators that these authors outline, we have identified three that can illustrate a positive preliminary evaluation of our study’s short-term outcomes. Firstly, the coordinated involvement of professionals from different specialties that perform a variety of functions within the hospital has facilitated their exposure to multiple viewpoints regarding the principal issues at stake. The constant exchange of ideas facilitated by the participatory approach provided for an enhanced knowledge of the systems in which the participants are implicated.

Secondly, the most recent developments of the project include the active involvement of two participating doctors who will conduct quick intervention cycles adopting behaviour change principles introduced by the present study. This effort demonstrates the integration and adoption of new process into every-day practice, an outcome that speaks to the meaningful involvement of staff, and the purposefulness of the approach to these key stakeholders in the hospital community. Changing practice is one of the most challenging goals for quality improvement, and the early adoption of new methods in the clinical context is regarded as a positive result of the participatory framework sought by our pilot study.

Finally, the participatory agenda that governs the present study has enabled choices that were created by users to be devised through all keys stages of the process, from the early assessment of the behavioural challenges to the development of solutions for on-site trials. Bratteteig and Wagner state that even when all decisions are not taken in a participatory fashion, the framing of choices by those impacted by the intervention can be regarded as a significant participatory result. Throughout this study, choices have constantly been constructed – via the activities and methods employed – and put to decision – via varied discussion sessions and voting systems – utilising a participatory approach. Considering the evidence from literature, the lessons learnt and preliminary results of our case study, we are confident to support that an integrative approach, combining participatory design and behaviour change constitutes a promising strategy for accomplishing effective and empowering quality improvement in healthcare service provision.

**Fernando Carvalho, MFA**
For the past twelve years, Fernando has been actively involved in academic and professional practice focusing primarily on healthcare product, process, and service design. He held teaching positions in both undergraduate and postgraduate programs in design and architecture in Brazil, the USA, and the UK. Fernando earned a Master of Fine Arts degree in Industrial Design from the University of Notre Dame, when he developed a hospital cradle for premature babies and a series of environmental interventions to improve the care delivered in Neonatal Intensive and Intermediate Care Units – the work was made in collaboration with a University hospital in Rio de Janeiro, and a regional referral hospital in the USA. Currently, Fernando is a PhD researcher at the Loughborough Design School, UK, focusing on the integration of Participatory Design and Behaviour Change methods to improve collaborative clinical practice in the British NHS. Mr. Carvalho is a *Science without Borders* scholarship recipient, his doctoral research is funded by the Ministry of Science, Technology, Innovations and Communications of Brazil.

**Gyuchan Thomas Jun, PhD**
Thomas Jun is Lecturer in human factors and complex systems at Loughborough Design School, Loughborough University, UK. He is a founding member of the Human Factors in Complex Systems Research Group. His research interest is in integrating systems thinking, design thinking and resilience thinking into the participatory design of complex socio-technical systems like healthcare. His particular expertise is in representing/analysing complex systems using systems theory, various system maps and system dynamics model. He is also interested in developing system interventions based on behaviour change theories and resilience engineering. He is also very keen to disseminate his research findings to a wider audience using an engaging story-based animation (YouTube: two contrasting views of South Korea ferry accident).

**Val Mitchell, PhD**
Val Mitchell graduated from Loughborough University with a degree in Ergonomics. After working as an ergonomist in a design consultancy in Sweden and in the health service, Val joined Loughborough University as a researcher. She has managed and worked on many research and consultancy projects particularly relating to the design of ICT and mobile communication product and services. Her PhD entitled: "Methods for Exploring User Needs for Future Mobile Products and Services" was conducted in collaboration with a major UK
manufacturer of mobile communication technologies. Val has over 20 years of multidisciplinary research experience specialising in the development of User Centred Design (UCD) and User Experience Design (UX) methodologies for eliciting user requirements for future technologies. She is particularly interested in the communication of user needs and requirements to designers using scenarios and personas and the design of creative Participatory Design and Co-design methods.
An Analysis of the Educational Value of PBL Design Workshops

Ikjoon Chang*, Suhong Hwang**

** Faculty of Division of Design and Art, Yonsei University, Wonju, Rep.Korea, suhongh@yonsei.ac.kr, Corresponding Author

The purpose of this study is to plan and operate design-workshops based on project-based learning (PBL), and examine their educational value for students. The PBL workshop encourages direct participation from students and produces educational value, and it is important to raise the interest level of workshops to elicit proactive participation. The workshop in this study was carried out over two weeks in January 2017 at Korea’s Yonsei University. The workshop was composed of eight teams of students from three countries, including Korea, China, and Japan, and the course was primarily divided into two sessions. The workshop participants examined in this thesis were notably satisfied with the elements of the course meant to garner interest. In the questionnaire results, participants also indicated that they obtained ample educational value through the workshop. An important element of the workshop was to connect the participants with businesses, which is also an important component of design education. Despite this, participants expressed a relatively lower level of satisfaction compared to other elements of the workshop. The results and analysis of this study will hopefully become a meaningful resource for educators when designing workshops in the future.

*keyword: Design Education, Workshop, Project Based Learning*

Introduction

Design education is a complex area of study that requires the delivery of knowledge in parallel with experiential learning. This is because design education courses always include time for students to produce work and receive feedback. In design, a piece of work is produced under a theoretical background and must reflect the user’s perspective. The commercial value of the piece can only be determined after evaluating its usability. The difference between art and design tends to be decided by whether or not the end result has a practical purpose. Art requires a complex interpretation in which the artist expresses their own thoughts and experiences through their work. Design, however, evaluates consumer usability while also considering the designer’s aesthetic impressions. In short, students aiming to become designers must receive constant feedback about their work and make adjustments in order to achieve a design that has realistic usability. In this context, workshop education can be utilized as an extremely useful educational tool for students aiming to become designers. In the design field, organizing a team to produce a unified result is viewed as more effective than relying on an individual to complete a given task. To accomplish this, communication, negotiation, and cooperation with team members are essential elements. The tendency in university curricula to evaluate work using grades, however, has resulted in competition often outweighing cooperation and sharing among students. Short-term workshops are an important educational tool that can make up for those shortcomings.

This study conducted experiments by grafting together the concepts of project-based learning (PBL) education in order to determine how to effectively organize a workshop in design education.
The workshop was conducted for approximately two weeks in January 2017 with Korean, Chinese, and Japanese students at Yonsei University in Korea. After the workshop ended, question items about several categories were made and used to examine the students’ opinions. The results, including interest level—an important characteristic of PBL education—and the students’ opinions, were indexed and used as evaluation data.

**Theoretical Background**

**Workshop Concept**

The workshop concept originally included a physical place such as a workspace or job site. Recently, however, the term workshop is being widely used as educational terminology that is synonymous with communal education and team-based education. The Merriam-Webster dictionary defines a workshop as an intensive educational program made up of a comparatively small number of people that focuses on acquiring skills in a particular field. In contrast with education methods that primarily rely on the delivery of information to participants, workshop education relies on participation-based courses. The origins of workshop education can be traced back to 1905 when George P. Baker of Harvard University took charge of drama-creation courses (47 workshops). This thesis defines a workshop as a short-term, intensive educational program, which focuses on project-based learning and experience-centered educational methods. The characteristics of a workshop can be understood and organized into five types. The first is member “participation” and the second is “experience.” When these two characteristics are synthesized participants actively combine their own experiences and enter the “negotiation” process in problem solving. The opinions formed in the negotiation process are then divided into two characteristics, “creation” and learning.” A graph of the workshop characteristics is shown in Table 1.

![Figure 1. Workshop structuring process](image)

**Approaching PBL**

The PBL education method helps students acquire knowledge and skills by focusing their studies on actual, complex questions, problems, and assignments. American education activist John Dewey has said, “When learners encounter an interesting problem, they learn how to research and think. Education is meant to help the learner’s experiential process, and a learner’s growth comes from the constant restructuring of experience, and the interaction between human activity and the
In other words, PBL is an educational method that enables learners to recognize a problem, experience the process of resolving that problem, and increase their understanding of knowledge. Thus, PBL can be considered as a type of self-directed learning, and is a method in which the participatory learner can actively access the essence of knowledge. By reestablishing the role of the educator, education becomes a space and opportunity where knowledge is not simply delivered, but experienced by learners.

The PBL grafted workshop and constructivism

Discussion through participation and experience are important characteristics in the typical workshop concept, but PBL allows for more detailed discussion. In design workshops based on PBL, it is important that the participant shows interest and actively searches for problems. If the participant reacts passively, that means they have already lost interest in the process. If they lose interest, the next step in finding solutions to the problem becomes impossible. In this manner, PBL workshops must constantly generate topics and environments reflective of the mood of the participants throughout the education process.

This is likely related to the emergence of behaviorism based on constructivism as an alternative to education. Because each learner has a different level of comprehension, they are constantly organizing knowledge and expanding it through interactions and discussions with their teachers and friends. The participant must go through that process themselves, and the educator or surrounding environment must provide a mechanism that supports learners during that process. In that same context, one can say a PBL workshop is successful when a participant achieves the result they intended.

![Figure 2. PBL Workshop Concept](image)

Table 2 shows the important process of the PBL workshop. It is difficult for educators to anticipate which direction the process will go when participants discover a problem and begin to resolve it. However, educators can influence the direction through feedback in the curve portion of
the table. If normal education is a straight line, then PBL can be viewed as experiential education composed of a series of curves.

The PBL Workshop Design

Workshop summary

The workshop in this study was carried out over two weeks in January 2017 at Korea’s Yonsei University. The workshop was composed of eight teams of students from three countries, including Korea, China, and Japan, and the course was primarily divided into two sessions. The first week was a preliminary assignment in which foreign students experienced Korea and looked for inconveniences they felt as foreigners. During the second week students engaged in team work to come up with designs to resolve those inconveniences. In short, the theme of the workshop was discovering methods to resolve inconveniences faced by foreigners visiting Korea.

Preparing with a company in the field

A mobile service company partnered with the workshop to achieve practical educational value. Business experts are able to provide students with an opportunity to more deeply approach design when constructing a method to solve a problem. For this, the workshop theme was narrowed down and modified to require students to develop mobile applications to resolve inconveniences faced by foreigners visiting Korea. In other words, mobile application was an opportunity for business experts to provide more detailed and diverse advice to students. Also, the workshop and presentations were divided into the school and business locations, and gave the students a more realistic sense, which increased their level of interest and engagement in the PBL workshop.

Final presentation

Students gave their final presentations after finishing the two-week course, which was followed by a review from the business experts and professors. This was an important tool for students to experience both the business perspective and the professors’ perspective. Students were also required to evaluate their final results and select the most exceptional group. Implementing elements that incited a sense of competition allowed the students to actively participate in the course without diminishing their enthusiasm.
Case Analysis and Consideration Questionnaire

When the workshop was finished, a diverse set of questions was given to the students to evaluate the educational value of the workshop. The questionnaire items were divided into environmental factors, interest factors, and educational factors. Table 1 shows the questions that were necessary for analysis. The questionnaire received answers on a 7-point Likert scale, and included 35 participants.

Table 1. Questionnaire Items

Questionnaire analysis

Environmental factors

Satisfaction with the workshop space and satisfaction with the company collaboration are shown in figure 5 and figure 6. When converting each answer to a value of 100 points, the satisfaction level of the workshop space was 72.86, and satisfaction level of the company collaboration was 66.19. The reliability of two answers (reliability of a question’s internal consistency) was relatively high, at
Interest factor

This next section covers the interest factor, which is an important element in PBL workshops. Questions were aimed at finding out how enjoyable the workshop was for students, whether they would be willing to attending this workshop again in the future, and if they would be willing to recommend this workshop to friends. There was a score of 70.95 regarding how enjoyable the workshop was when converting the Likert scale to 100 points. Willingness to attend the workshop again received a score of 72.86, and willingness to recommend the workshop to a friend received 77.14 points.
The reliability of the three answers (reliability of a question’s internal consistency) was very high at 0.974. Figure 7, Figure 8 and Figure 9 show graphs of the results of the interest factor.

**Educational Factor**

There were three questions to evaluate educational factors, including questions regarding whether students had smooth communication with their team members in the workshop, how much they felt their ideas were reflected in the final results, and how much the reviews from experts and professors influenced their end results. There was a score of 69.05 regarding the question about communication when converting the Likert scale to 100 points. The question regarding how much of the students’ ideas were reflected received a score of 59.52 points, and the influence of feedback on the end result received a score of 68.10 points. The reliability of the three answers (reliability of a question’s internal consistency) was very high at 0.914. Figure 10, Figure 11 and Figure 12 show graphs of the educational factor results.

Figure 8. Willingness to attend again

Figure 9. Willingness to recommend

Figure 10. Communication level
Considerations

The most important part of this workshop while using PBL was to consistently maintain the students’ interest and their sense of educational tension throughout the course. The fact that interest factor scores were higher than scores in other factors is meaningful in this sense. The reason the score for willingness to recommend the workshop to a friend (77.14) was 4 points higher than willingness to attend again (72.86) may be due to a tendency to prioritize new experiences over repeated experiences that may occur by attending same workshop twice. The workshop enjoyment score (70.95) was lower than the score for willingness to attend again, which demonstrates that the design of the workshop was lacking a mechanism to incite the students’ interest.

In educational factors, the relatively low score for reflection of personal ideas (59.52) compared to the other two categories can be interpreted as the result of several opinions taking precedent over the opinion of one person in a team setting. Had scores for the reflection of personal ideas been high, this would have run counter to the goal of the workshop which sought to help students arrive at new knowledge through a collaboration of their experiences.

Lastly, in environmental factors, the relatively low score for satisfaction with company collaboration (66.19) in comparison to all other categories was somewhat disappointing in that the design of this workshop viewed company collaboration as an important educational mechanism. Further research will need to be conducted to determine how company participation influenced the students.
Conclusion

In current university education, design workshops are actively taking place in numerous domains. Workshop education has the advantage of delivering diverse experiences to students that universities are unable to provide. However, there are still many ambiguous aspects about the act of “experiencing,” in terms of what kind of educational value it has for students, and how that experience is delivered. In that sense, the design and analysis of this workshop, with more indexed data, can become a meaningful resource in the design of other workshops in the future. Also, PBL theory has the same context as the workshop’s goal to deliver knowledge through experience. The device setting Table 2 that addresses which direction the workshop will lead the student’s process, and what educational results will thereby be achieved can be utilized as a meaningful resource for educators when designing workshops.

Suhong Hwang is a graphic designer and researcher. His researches are focused on identity design, interface design and design education. He studied Visual Communication Design at Seoul Nation-al University, and achieved two Master degrees at Seoul National University, Rep. of Korea and School of Visual Arts, New York, U.S. He also has a lot of experience as graphic designer in pro- fessional field, Neowiz Inc. Korea and Samsung Opentide. Currently, he is an Assistant Professor at the Division of Design and Art in Yonsei University, Rep. of Korea.
Rewarding Risk: Exploring How to Encourage Learning that Comes from Taking Risks

Dennis Cheatham, Miami University, Oxford, Ohio

Abstract

High-stakes testing that became the norm after the No Child Left Behind Act of 2001 helped condition students to strive for correct answers for clear problems, all on the first try. However, the iterative process inherent in designing requires risk-taking to conduct a trial-and-error process of defining problems and exploring possible solutions. This design research project was operated with Miami University Graphic Design students to test their willingness to take risks in their coursework to achieve their self-defined measures of success. Students identified that improving their skills was how they defined success. An interaction design assignment involving front-end coding was modified to test students’ comfort taking risks to grow their skills. Most students took risks in the assignment to grow their interaction design skills. The project revealed that closer attention to student motivation when developing learning experiences could help students make the transition to practicing design as an iterative process fraught with risk.

Keywords: Design education, risk, testing, performance anxiety, interaction design

Primary and secondary education in the United States is prescribed and linear, heaping pressures on students to perform on standardized tests and achieve high grades. However, the design process requires risk, posed as incremental “failures” inherent in the iterative process. These opposing conditions can create challenges for students who are accepted into design programs in higher education. For this reason, I developed a design research project in the scholarship of teaching and learning (SOTL) that exists at the intersection of performance-driven testing habits and risk-laden design process.

The objective of this research was to discover what curricular formats could encourage students to risk failure by attempting innovative outcomes that exceed prescribed learning objectives. Findings from this research was geared to inform the development of implementable curricular structures for facilitating learning that took into account the conditioned culture of students today. The result was the Rewarding Risk project, operated in the Graphic Design program at Miami University in Fall 2014 and Spring 2015.

Literature Review

Over the past ten years, teachers and researchers have reported increasing cases of performance anxiety in primary and secondary school students. This drive to achieve
high grades has caused these students to act out a range of damaging behaviors (Kessler, n.d.). The pressure to achieve high grades, especially on standardized tests like those administered to measure performance under the No Child Left Behind Act of 2001, has led to concerns for young adults’ mental and physical health (Rubin, 2012). High-stakes tests like the SAT, ACT, and other state-specific exams have been found to hurt student learning while shifting teaching attention away from learning in content areas that were not on tests, including the arts (Amrein & Berliner, 2003). The culture of high-stakes testing and academic pressure to achieve high grades has conditioned students to be motivated to produce correct answers to defined problems.

Design “problems” are not jigsaw puzzles and seldom have correct “solutions” (Lasky, 2005). Designing involves a process of iteration instead of arriving at a single, “correct” solution on the first try (Norman & Verganti, 2014). Working iteratively requires that designers become comfortable with trial and error—a process that is not easily learned (Hartford, 2011, p. 31). This process requires self-confidence as the problem and solution are simultaneously redefined and converge (Cross, 2006). While standardized testing hinges on “correct” answers, much of design involves reframing problems to arrive at ideal outcomes (Kolko, 2010). The complex nature of the design process is steeped in uncertainty and “working things out,” requiring designers to become comfortable taking risks (Poggenpohl & Winkler, 2010).

Context

The Graphic Design program at Miami University is situated in the Department of Art, which resides in the College of Creative Arts. The program is selective and requires applicants to submit a portfolio of work for review before they are admitted into the program. In advance of the portfolio review, prospective students are required to complete a range of Art Foundations courses, including courses in drawing, color theory, two and three-dimensional design, creative technology, and problem solving. About 20 students are admitted into the Graphic Design program each fall. A total of about 60 students are enrolled in the Graphic Design program each year, which consists of a “lock-step” schedule of design studios that spans three years. The program uses a cohort model, where a class of students are admitted into the program and stay together in the same graphic design cohort through completion of a BFA in Graphic Design. In Spring 2017, most students enrolled in the Graphic Design Major were natives of the mid-west United States, two students were from Korea and one was from China.

Research Methods

Surveys and instruments for this research project were developed in Fall 2014 and Institutional Review Board (IRB) Approval was obtained for the project prior to each phase of its operation. A website was developed and hosted at http://rewardingrisk.designworkbench.com where surveys were conducted for the project. The project was operated in several phases over the Fall 2014 and Spring 2015 semesters and featured three research activities:
- **Risk Taking and Success Survey**: Learn how Graphic Design students at Miami define success in their design coursework and if they would be motivated to take risks in order to achieve it.

- **Digital Broadsides Assignment**: Modify an existing assignment to test if Graphic Design students at Miami would take risks in their design coursework to achieve their success measure.

- **Focus Group Follow-up**: Learn about risk-taking in design and the effects of the modified assignment structure.

**Risk Taking and Success Survey**

In Fall 2014, a survey was designed to learn how students in the Graphic Design program at Miami University defined success in their coursework. Participation in the survey was open for two weeks and was made available to all 59 students enrolled in the Graphic Design Major at Miami at that time. Participation was voluntary and participants remained anonymous. 19 students completed the survey, representing 32% of students in the program. The survey consisted of seven questions developed to determine how participants defined success in their coursework, if they would be willing to take risks to achieve these goals, and what rewards (if any) they would wish to receive for taking such risks. Most questions in the survey were responded to by clicking radio buttons, and one used a textbox where participants could share thoughts using their own words.

Options for radio buttons in the survey were developed to learn if students’ overriding motivation was purely intrinsic (strong design skills and increased knowledge), extrinsic (praise from instructors and fellow students), or extrinsic and specifically quantified (high grades). An option was also provided to allow participants share if they were not yet sure what motivated them (I don’t know yet). The questions and results of the survey can be found in Table 1.

The Digital Broadsides Assignment

An assignment from the Art 254, Fundamentals of Interaction Design course was modified so it could be used to learn if students would take risks to achieve their reported measures of success from the Risk Taking and Success survey. The Fundamentals of Interaction Design course was ideal for this research because it was a required course for all first-year Graphic Design Majors, ensuring most students would participate in the project before they had completed other front-end coding courses. Of the 19 first-year Graphic Design students enrolled in the course, 15 students reported they had no prior experience writing front-end code to create functioning websites. The fact that participants were new to front-end coding meant that using a code-heavy assignment would simulate the effects of taking risks when designing with new tools and applying new processes.

An assignment titled Digital Broadsides was selected to test student performance where design iteration and risk-taking was involved. This assignment was created in Spring 2014 and required students to write HTML and CSS to re-create a 19th or 20th century broadside poster using web fonts and limited imagery. Digital Broadsides was operated within the first four weeks of the ART 254, Fundamentals of Interaction Design course. For this project, students were assigned a digital image of a broadside poster. Over three class periods (one week), students participated in all-class critiques, revising and refining
their coded posters over that period of time. After the 1-week cycle was completed, the process was repeated a second time with each student attempting to re-create a different, more complex poster design. The two-week cycle resulted in the production of two different digital broadside posters created with HTML and CSS.

For this research project, the *Digital Broadsides* assignment was modified to learn if students would take risks in order to achieve measures of success indicated in the Risk Taking and Success Survey administered the previous semester. A majority of responses to this survey revealed that students’ ideal success measure was “strong design skills and increased knowledge.” Most students also responded that if they were to fail, they would not give up and would keep trying.

In Spring 2015, 19 students were enrolled in Fundamentals of Interaction Design course. This group of students was not assigned a *Digital Broadsides* poster to re-create as the way the assignment had been operated in 2014. Instead, students were allowed to select a level of difficulty they wished to attempt for the assignment. *Digital Broadsides* poster options were posted on the course website for students to download and these poster options were categorized in easy, medium, and hard difficulties as shown in Figure 1. Each student was instructed that once a difficulty level was selected, they could not switch to another difficulty level. Students were reminded that the focus of the assignment was learning key aspects of front-end coding instead of producing “perfect” work. The goal of this portion of the research project was to see if students would take risks by selecting challenging difficulty levels for the assignment, indicating they were willing to take risks to learn more advanced front-end coding skills. The rationale of this approach was if students truly felt that “strong design skills and increased knowledge” was their primary success measure, they would be likely to select a level of difficulty that would be beyond their current skill and comfort level.
The assignment was started on a Monday and students brought their completed work to class on Wednesday to be displayed on a projected screen for critique and discussion. During critique, issues were diagnosed, successes and weaknesses were identified, and areas for growth were discussed. The learning from this experience took place largely doing the critique session. After the initial critique, students completed a Digital Broadsides Feedback Survey where they shared their reactions to the experience. The details of this survey will be addressed below.

Following the completion of initial poster design, another round of the Digital Broadsides project was assigned. This time, participants had the opportunity to select another level of difficulty to attempt that was equal to or more difficult than their initial selection. This round of the assignment was operated over the next week and its process was identical to the first round.

Digital Broadsides Feedback Survey

After the Digital Broadsides assignment concluded, an anonymous survey was operated to learn participants’ risk-taking experiences when completing the assignment. Questions and responses can be viewed in Table 2. The focus of the Digital Broadsides Feedback
Survey was to learn what difficulty level each participant selected, why they selected this level, and if they felt they took a risk when selecting this difficulty level. This survey was hosted on the research project website.

Analysis

Analysis of qualitative data gathered from the two surveys and the focus group was guided by processes in Jonny Saldana’s *The Coding Manual For Qualitative Researchers* (Saldaña, 2009) and the discovery of themes in this data was assisted by Gerry and Russell’s article *Techniques to Identify Themes* (Ryan & Bernard, 2003). Text and the focus group audio were uploaded to Dedoose, (SocioCultural Research Consultants, 2014) a qualitative research online tool, and independently reviewed by the author twice over the course of one week. This process resulted in 22 different codes that congealed into three distinct themes. Each of these codes were determined based on frequency counts and the most frequently occurring codes became themes which will be discussed below.

Results

The results of this study suggested that, when given a chance to own their learning in an environment where risk was part of the iterative process, most students chose to challenge themselves. Written responses revealed that taking risks was still a concern for students and that they feel pressure to get high grades in their coursework. Findings highlighted the importance of process-centric assignment objectives for shifting
students’ attitudes toward attempting untried approaches.

The initial survey for this study (Represented in Table 1) serves as the baseline assessment of participants attitudes on risking failure in coursework and their willingness to take risks to succeed. 15 out of the 19 participants (79%) stated that “strong design skills and increased knowledge” was their ideal success measure and 17 out of 19 (89%) responded they would take risks to achieve their goals. A majority (16 out of 19, 84%) stated if their attempted design failed, they would not give up and would keep trying. The most motivating reason for designing according to participants was “the fun of making things and solving problems” (11 out of 19). The final question of this survey which addressed participants’ ideal rewards for taking risks, did not render a clear preference.

Several responses to the question why participants selected “strong design skills and increased knowledge” as an ideal success measure signified intrinsic motivators were especially important for driving achievement.

I believe the ability for a designer to learn new concepts and skills outweighs grades and style... – A Graphic Design Senior

The best feeling for me personally after taking a risk happens the night before I turn the project in. It is a great feeling knowing you went for something that could backfire and trying it anyway... – A Graphic Design Senior

The Digital Broadsides Assignment portion of the research allowed students to select their own level of risk on an assignment. Following this assignment, participants shared their thoughts via the Digital Broadsides Feedback survey presented in Table 2. Of the 14 students who participated in the survey, 10 (71%) selected “medium” or “hard” difficulties. 10 out of 14 participants were “glad they selected the difficulty they did.” These 10 participants were among the group that selected the most difficult levels (medium and hard), which suggests that risk-taking was acceptable for those who were motivated to grow their knowledge and skills. A comparison of work from the 2014 class to the 2015 class revealed significant improvement in the quality of the aesthetic of the posters as well as students’ coding skills.

Figure 5: Digital Broadside student work from 2015
Focus Group

Two weeks after the completion of the Digital Broadsides Assignment, a focus group was operated with students in the Fundamentals of Interaction Design course to discuss topics explored in the research project. This semi-structured focus group included questions that covered topics like the design process, academic pressures and grades, and barriers that inhibit experimentation. The focus group lasted one hour. This session was designed to bring together all of the topics addressed by the project into a more informal discussion. An audio recording was captured during the session and consent was obtained by all participants.

During the focus group, students were asked about risk-taking when it comes to solving difficult tasks in design. In the Fundamentals of Interaction Design course, most coursework was completed outside of scheduled class meetings. Students shared that working through front-end coding assignments was typically not a solitary process. Students indicated that they preferred to work together to solve challenging front-end coding problems—sharing discovered tutorials and resources at places like Stack Overflow, W3 Schools Online, and GitHub. The unfamiliarity of front-end coding prompted the class to collaborate more than they usually did when producing print-based design work.

Both survey data and focus group responses revealed that students valued working through and overcoming challenging problems. Several quotes from the focus group portion of the research are evidence of this sense of accomplishment:

Figure 6: Students from the Fundamentals of Interaction Design course participating in the focus group
“You feel like you have so much power when you solve a coding problem.”

“I don’t know how to do that, but search how to do it and figure it out. Exploring some- thing new and figuring it out is fun and rewarding. It’s exciting.”

“Even when you feel like you know what you’re doing, it still doesn’t do what you want so you have to put a lot more effort into making it look the way you want it to look—so I think it just feels more rewarding.”

These statements and the fact that most students indicated they would be willing to take risks and keep trying if they failed suggests that a sense of accomplishment is a valuable learning outcome for design curriculum. This suggests that assignments that are designed to evoke senses of accom- plishment on an emotional level could increase risk-taking and learning in coursework. Further work to explore how Vroom’s Expectancy Theory could be applied to design learning and achieve- ment is warranted (Hoffman-Miller, 2013).

Limitations

The limited sample size of this research reduces the generalizability of findings and positions the project as an exploratory study. While students in 2014 and 2015 completed the same assignment, students in the 2015 class may have been more aware of the “risk” nature of the project because they were primed by the initial risk survey, possibly leading to increased effort on the assignment. In spite of these limitations, findings still reveal areas for potential research into how learning and risk-taking may be encouraged.

Conclusion

Students who have been conditioned to find correct answers and the formulas that can produce them are locked into a mode of summative assessment that can be closed off to iterative processes involved in design. In order to make risk part of learning, a focus on formative assessment is im- portant. The Digital Broadsides assignment where students could select their own assignment dif- ficulty level resulted in most students gaining valuable skills, but it also facilitated learning where process was the main focus.

Since completing this project, I have begun to develop several assignments to test how process may become a more important part of design coursework than final outcomes. By weighting pro- cess work grading heavier than final outcomes, students may become more attentive to the iterative process, striving to produce higher quality versions instead of trying to isolate the best “final” solution. This project has also revealed that allowing students to self-select assignment difficulty levels may have some value for helping students own their learning and take on personalized chal- lenges. While this small study revealed that most students selected a more difficult level than would have been originally assigned, more research is needed to test this notion.

Risk is inherent in the design activity. The iterative process involves trial and error, and risks must be taken in order to innovate and refine design outcomes. In order to explore how to
encourage risk-taking that may lead to innovative design outcomes, priority should be placed on developing new models for facilitating learning and assessing work.

Dennis Cheatham is an Assistant Professor of Communication Design and is Graduate Director of the Experience Design MFA at Miami University in Oxford, Ohio, United States. He researches ways people and design decisions intersect at experiential and systemic levels. Dennis is a Scripps Gerontology Center Research Fellow and work is focused on end-of-life choices and topics in aging, specifically advance care planning and aging in underserved populations, hosted at livvalues.designworkbench.com. Prior to his academic appointment, Dennis practiced design professionally for fifteen years as a creative director, graphic, interaction, and experience designer at agencies, in-house, and non-profit organizations mostly in the Dallas/Fort Worth, Texas area. Dennis holds a Master of Fine Arts in Applied Design Research from the University of North Texas as well as a Bachelor of Fine Arts in Communication Design and a Bachelor of Arts in Creative Writing from Texas Tech university.
Design for Better Comprehension: Design opportunities for facilitating consumers’ comprehension of really new products (RNPs)

Abstract

Developing successful RNPs can bring competitive advantages for companies. However, the success rate of RNPs are relatively low because consumers often feel resistant to adopt them. One reason for consumers’ resistance is their lack of comprehension of RNPs. To facilitate consumers’ comprehension, this paper conceptually discusses the opportunities related to designing the appearances of RNPs. More specifically, to facilitate consumers’ internal and external learning, this paper explores four underlying mechanisms: 1) product appearance as a visual cue to trigger category-based knowledge transfer, 2) to trigger analogy-based knowledge transfer, 3) product appearance as an information carrier to communicate innovative functionality directly, and 4) product appearance as a way to trigger congruity with innovative functionality of RNPs. The rationales for each underlying mechanism are conceptually discussed, supported with relevant empirical evidence and examples found in the markets.

Keywords: Consumers’ comprehension, consumers’ internal learning, consumers’ external learning, really new products (RNPs), product appearance.

Designers are frequently involved in developing really new products (RNPs), which can gain competitive advantages for companies (Dougherty, 1992). RNPs (a.k.a. discontinuous or radical innovations) refer to new products that integrate advanced technology that has rarely been used in the industry before and enables consumers to do things they were previously unable to do (Garcia & Calantone, 2002; Song & Montoya-Weiss, 1998). For example, a smart home system is a RNP that connects a network of sensors and an information terminal to collect immediate information at home. Through an app on a smart phone, consumers can monitor and control situations at home distantly, which consumers could never do before. In contrast to RNPs, incrementally new products (INPs) integrate current technologies. INPs (a.k.a. discontinuous or radical innovations) provide new benefits, features, or improvements on existing products. For instance, the launch of the first iPhone was considered a RNP, while the later versions (e.g., iPhone 6) are considered INPs because they provide incrementally functional improvements based on previous versions.

Although successful RNPs can provide companies with competitive advantages, the success rate of RNPs is relatively low (Cooper & Kleinschmidt, 1987) The success of RNPs ultimately depends on consumers’ adoption of RNPs (Hauser, Tellis, & Griffin,
2006). However, consumers often feel resistant to adopt RNPs (Ram & Sheth, 1989). One of the reasons for consumers’ resistance is consumers’ lack of comprehension. Different from INPs that consumers can understand relatively easily based on accumulated knowledge and experience, gaining comprehension of RNPs is difficult for consumers (Hoeffler, 2003). They may not understand how RNPs work and what benefits RNPs can provide (Hoeffler & Herzenstein, 2011) because the knowledge that is needed to understand the new technology goes beyond consumers’ current knowledge (Gatignon & Robertson, 1985) and the integration of really new technology also calls for completely different ways of thinking and new usage patterns (Veryzer, 1998).

**Consumers’ comprehension of RNPs**

Gaining comprehension of RNPs is important because it is a precondition for consumers’ further evaluation and adoption of RNPs (Reinders, Frambach, & Schoormans, 2010; Veryzer, 1998). Based on consumers’ adoption process, it is suggested that consumers go through five stages to adopt a RNP (Rogers, 1995), as outlined in figure 1. In the first stage, the knowledge stage, consumers become aware of a RNP and have some initial ideas of how it functions. As consumers may not have any experiences with the RNP up to that point, the comprehension obtained at this stage is predominantly a subjective comprehension of the RNP. Consumers may feel that they lack comprehension of the RNP and its innovative functions, resulting in a feeling of discomfort and confusion. They may also feel confident that they understand the RNP and its benefits. After the knowledge stage, the persuasive stage starts, in which consumers form a favorable or unfavorable attitude. Next, at the adoption stage, consumers engage in activities that lead to a choice to adopt or reject the RNP. The implementation and confirmation stage follows, where consumers use and evaluate the RNP. According to this framework, consumers are supposed to carefully learn and consider the potentials of RNP during the persuasive and decision stages, and make an adoption or rejection decision afterwards. The resistance to a RNP results from a serious and careful consideration and evaluation of a RNP. However, recent research has pointed out that consumers’ resistance to RNPs does not, in fact, involve a serious evaluation of the RNP (Talke & Heidenreich, 2014). In most cases, consumers’ initial resistance towards a RNP is established early in the knowledge stage. If consumers feel that they lack comprehension of a RNP, the resulting confusion can result in initial resistance to the RNP. This resistance then stimulates these consumers to disregard its potential and subsequently reject it. Therefore, it is crucial to ensure that consumers comprehend RNPs at the knowledge stage.

![Figure 1. The innovation-decision process (Rogers, 1995)](image)

To facilitate consumers’ comprehension of RNPs, several effective marketing strategies have been developed in marketing research. Consumers’ comprehension of RNPs can be facilitated through internal and external learning (see figure 2). Consumers can learn RNPs through making use of the internal stored knowledge, which is termed as consumers’
internal learning. Specifically, it is possible to facilitate consumers’ internal learning through transferring internal knowledge from a familiar domain to a RNP, such as the usage of categorization (Moreau, Markman, & Lehmann, 2001), analogical learning strategy in advertisements (Gregan-Paxton, 2001; Gregan-Paxton & John, 1997), and product bundling (Reinders et al., 2010). Consumers can also learn RNPs from external sources, such as advertisements, websites, other consumers, product demonstrations and direct experience with the RNP. Learning from external sources is defined as consumers’ external learning (Hoeffler & Herzenstein, 2011). It is possible to facilitate consumers’ external learning by mental stimulation (Dahl & Hoeffler, 2004; Hoeffler, 2003) and exposing consumers to RNPs and demonstrations of RNPs (Hoeffler & Herzenstein, 2011). In addition, product appearance may influence how consumers respond to RNPs (Mugge & Dahl, 2013). Product appearance can serve as a visual cue for consumers’ categorization of a RNP (Rindova & Petkova, 2007). By looking at a product appearance, consumers can identify which category the product belongs to, which could further trigger category-based or analogy-based knowledge transfer, leading to enhanced consumers’ comprehension. Moreover, product appearance can directly communicate the innovative technology of a RNP through visualizing the innovative technology (Eisenman, 2013). For example, Dyson vacuum cleaner adopts the innovative dual-cyclone technology which requires multiple cyclones to produce airflow. The product appearance exposes these cyclones rather than hiding them, aiming to communicate how the innovative technology works. However, designing product appearances to facilitate consumers’ comprehension only received limited research attention so far, even though product appearance also carries the potential to facilitating consumers’ internal and external learning of RNPs (Cheng & Mugge, 2015, 2016; Mugge & Dahl, 2013). To fill in this gap, this paper aims to conceptually explore the potentials of product appearance for influencing consumers’ comprehension of RNPs.

**Figure 2. Current marketing strategies for facilitating consumers’ learning of RNPs.**

**Consumer responses to product appearance**

The value of designing product appearances has been well acknowledged. Product appearance can contribute to companies’ financial performances (Candi, 2010; Hertenstein, Platt, & Veryzer, 2005), facilitate brand recognition (Person & Snelders, 2010), influence investors’ behaviors in the stock market (Aspara, 2012), and elicit a variety of consumer responses (Bloch, 1995). By seeing a product appearance, consumers can process it cognitively, generate emotional responses towards it, and form behavioral responses by triggering a tendency to either approach or avoid the product (Bloch, 1995; Crilly, Moultrie, & Clarkson, 2004). While processing a product appearance cognitively,
consumers can form aesthetic impressions and gain symbolic associations. In addition, consumers can draw some inferences concerning the product, also termed as product beliefs (Bloch, 1995), such as to which product category a product belongs to, what a product does, how effective a product performs, and how to operate it (Creusen & Schoormans, 2005).

Furthermore, previous studies have pointed out that product appearance plays different roles along the different stages in a product life cycle (Eisenman, 2013; Person, Schoormans, Snelders, & Karjalainen, 2008). In the product maturity stage where products are difficult to differentiate from each other in terms of functionality, product appearance can be used to differentiate from competitors in the cluttered market. For example, in the automobile industry, similar to introducing innovative technology, designing novel appearances can also stimulate the sale volumes (Talke, Salomo, Wieringa, & Lutz, 2009). Differently, in the early stage of the product life cycle where markets have little understanding of the radical technology, the prominent role of product appearance is to communicate the innovative technology (Eisenman, 2013; Rindova & Petkova, 2007; Simoni, Cautela, & Zurlo, 2014). As suggested in prior, while embodying RNPs, companies can design the appearances of RNPs to explain what the RNP does, explain the complex innovative technologies within the RNP, and how the RNP should be used, in order to facilitate consumers’ comprehension of the RNP (Eisenman, 2013).

Although the conceptual importance of using product appearances to communicate innovative technology of RNP has been highlighted in previous studies (Eisenman, 2013; Rindova & Petkova, 2007; Simoni et al., 2014), in the design research area, only limited research attention has been paid to investigating it to provide practical guidelines for designers. Thus far, only several empirical studies have been conducted to examine how different appearance attributes (i.e., typicality, visual complexity, and transparency) influence consumers’ processing of RNPs (Cheng & Mugge, 2015, 2016; Mugge & Dahl, 2013). However, it is important to explore the possibilities of designing product appearances to influence consumers’ comprehension of RNPs because designers are responsible for embodying RNPs and designers have the intention to assist consumers in comprehending a product through its appearance (Crilly, Moultrie, & Clarkson, 2009). More importantly, for many RNPs, the integrated technology in the RNPs does not fundamentally influence the product appearances or only to a certain extent, and thus product appearances are not completely predefined by or dependent on the integrated technology (Rindova & Petkova, 2007). Then, designers have the freedom to embody product innovations in different product appearances and thereby deliberately facilitate consumers’ learning. For example, when the first e-book readers were launched into the market, the technology allowed the product to be designed in any shape. Nevertheless, the product was designed to resemble a physical book to help consumers understand that e-book readers are used for reading (Hekkert & Cila, 2015). Therefore, it is both necessary and urgent to equip designers with the knowledge on how to embody RNPs to influence consumers’ comprehension.

This paper aims to conceptually discuss the possible opportunities for designing product appearances to influence consumers’ comprehension of RNPs. Based on current marketing strategies for facilitating consumers’ internal and external learning, we discuss how product appearances of RNPs can influence both learning strategies (see figure 3). Specifically, product appearances of RNPs can serve as a visual cue to trigger consumers’ internal learning through category-based and analogy-based knowledge transfer. To
facilitate consumers’ external learning, product appearances of RNPs can serve as an information carrier to communicate the innovative technology of RNPs. Product appearances of RNPs can also be used as a way to indicate the innovative functionality of RNPs by triggering a congruity between product appearance and functionality, which further influences consumers’ learning process of RNPs. These four kinds of design opportunities are discussed in the next sections. The underlying mechanisms for design opportunities are discussed firstly, supported by empirical evidence and corresponding examples.

Figure 3. The potential of product appearances for facilitating consumers’ internal and external learning of RNPs.

**Designing product appearances to facilitate consumers’ internal learning**

One of the barriers for consumers’ comprehending RNPs is the lack of knowledge (Gatignon & Robertson, 1985). RNPs are truly new, and thus there is no available knowledge stored in consumers’ memory that is ready for explaining RNPs. However, it is possible to make use of consumers’ stored knowledge related to other products and objects to facilitate consumers’ learning of RNPs. Previous research demonstrated that category-based knowledge transfer and analogy-based knowledge transfer are effective to help consumers’ learning of RNPs. Previous research demonstrated that category-based knowledge transfer and analogy-based knowledge transfer are effective to help consumers’ learning of RNPs.

**Product appearance as a visual cue to trigger category-based knowledge transfer**

By definition, one of the characteristics of RNPs is the uncertainty to be categorized the innovation as a member of a specific product category (Lehmann, 1994). Because a RNP often provides highly innovative functionality, the conceptual distance between the RNP and existing product categories is large, due to which the RNP cannot be readily assigned to an existing product category. However, the large conceptual distance between a RNP and existing product categories actually gives managers the freedom to choose the positioning of the RNP (Hoeffler & Herzenstein, 2011). Managers can position the RNP as belonging to an existing product category, aiming to activate consumers’ category-based knowledge transfer. For example, when the smartphone was launched, it could be categorized into the product category of a cellphone because it provided the same function for making
phone calls as cellphones did. However, it could also be categorized into the product category of computers because it integrates computer operating system. The smartphone was still labeled as a cellphone, aiming to help consumers transfer the knowledge from the cellphone category to the RNP.

To trigger category-based knowledge transfer, previous studies concluded that it is necessary to provide category cues for consumers (Gregan-Paxton, Hibbard, Brunel, & Azar, 2002). In terms of different category cues, previous studies have demonstrated that consumers are more influenced by visual cues than conceptual cues (Gregan-Paxton, Hoeffler, & Zhao, 2005). For example, for a smartphone, when presenting consumers a picture of a cellphone (visual cue) but labelling it as a computer (conceptual cue), consumers tend to perceive it as a cellphone, because the conceptual cue informs what the product does while visual cue defines what the product is (Barton & Komatsu, 1989).

In line with above, product appearance can serve as a visual cue for consumers’ categorization of a RNP. After carefully deciding the position of the RNP, designers can design product appearance to resemble the product prototype in this product category. For example, the first smart phone resembles a traditional cellphone (see figure 4). Typicality of the product appearance determines the ease of consumers’ categorization (Creusen & Schoormans, 2005). Previous studies have also empirically demonstrated that a typical-looking RNP can be categorized with more certainty (Goode, Dahl, & Moreau, 2013) and fewer learning costs (Mugge & Dahl, 2013), which could further lead to enhanced consumers’ comprehension. Thus, when seeing the RNP, consumers can recognize the RNP as a member of the product category. Subsequently, the category-based knowledge transfer process is activated. Consumers can make use of the knowledge from this product category to learn about the RNP, leading to enhanced consumers’ comprehension.

![Figure 4. Picture of the first smart phone: IBM Simon launched in 1994 vs. picture of a typical cellphone at that time: Motorola 8900X2, launched in 1994](image)

Labelling a RNP as a member of an existing product category indicates a match between the RNP and the product category (Gregan-Paxton & Moreau, 2003). Such category-based knowledge transfer encourages an extensive knowledge transfer from the product category to the RNP, which maximizes within-category similarity while reduce similarities across categories (Medin & Schaeffer, 1978; Rosch & Mervis, 1975). As a result, within a RNP, consumers may gain good comprehension towards the parts that shared similarities with the product category. However, for the innovative features of the RNP that differ from the existing product category, consumers may not comprehend very well. For instance, in the example of smartphone, consumers may understand this smartphone is used for making
phone calls, but consumers may encounter difficulties while comprehending other functions, such as providing different applications, making pictures, etc.

Product appearance as a visual cue to trigger analogy-based knowledge transfer

In addition to labeling RNPs as a member of a particular product category, marketers can consider establishing a totally new product category for RNPs (Hoeffler & Herzenstein, 2011). The introduction of a smart home system is such an example, which was not assigned into any existing product category but established a new one. In this case, although no available knowledge can be transferred from an existing product category, it is still possible to help consumers learn these RNPs through analogy: by relating the RNP to a familiar product or concept, termed as a source (Gregan-Paxton & John, 1997). The RNP does not need to be closely related to the source. Instead, a strong similarity shared by the RNP and the source can make a sound analogy. For example, a smart home system was introduced to the markets with the analogy of “mother” (see figure 5). A smart home system does not relate to a mother at first glance. But the functions of a smart home system that collects all the information around home can be comparable to the role of a mother at home who often knows everything surrounding home.

Analogy-based knowledge transfer refers to knowledge transfer from an independent source (e.g., a mother) to the target domain (e.g., a smart home system) (Gregan-Paxton & John, 1997). It contains three steps: 1) identification of the source domain, 2) mapping the source domain to the target, and 3) transferring the knowledge from the source domain to the target. Prior research has demonstrated that when describing a RNP with an analogy in an advertisement, consumers’ comprehension of RNPs will increase because consumers can identify the source, build the association between the source and the target, and transfer important characteristics from the source to the target (Houssi, Morel, & Hultink, 2009).

To facilitate consumers’ learning through analogy, designers can consider designing appearances of RNPs to resemble a source product or concept, in order to trigger consumers’ recognition of the relationship between a RNP and a source. Product metaphor is such a specific way to design a product appearance that “intentionally reference the physical properties of another entity” (Hekkert & Cila, 2015). A product metaphor relates a
source and a target product physically and conceptually. On the physical level, the product resembles the shapes of the source. On the conceptual level, the product and the source are associated in terms of certain meanings (Forceville, Hekkert, & Tan, 2006; Hekkert & Cila, 2015; Van Rompay, 2008).

When a product metaphor is used to embody a RNP, these two levels of associations make the product metaphor promising to facilitate analogy-based knowledge transfer for consumers’ learning of the RNP. On the one hand, the physical similarities can help consumers to identify the source domain (Forbus, Gentner, & Rattermann, 1993). On the other hand, within a product metaphor, the conceptual association between a RNP and a source is already integrated, which becomes a basis for analogical learning. For example, “Mother” is a smart home system that is embodied in the product metaphor of a mother (see figure 6). On the physical level, the design of “Mother” resembles the shape of a doll, which attempts to remind consumers thinking of the role of a mother at home. On the conceptual level, the association is built between the smart home system that collects all the information surrounding the home and a mother who often knows everything at home. As a result, consumers can gain better comprehension of the smart home system.

![Conceptual Level](image1)

**Conceptual Level**
- The smart home systems collects all the information surrounding home.
- A mother who often knows everything at home.

![Physical Level](image2)

**Physical Level**
- The appearance of the smart home system.
- A shape of a doll.

![Figure 6. Two levels of product metaphors](image3)

When using product metaphors in RNPs, designers firstly need to carefully select sources probably by working together with marketers. This source should share important similarities with the target RNPs. Next, designers need to make sure the source is well integrated into the product metaphors. As visual metaphors often carry the risk of multiple interpretations (Van Rompay & Veltkamp, 2014), it is crucial for designers to ensure that the product metaphor they designed only directs to the selected source domains. In the example of “Mother,” consumers may link the product design to multiple sources, such as a Russian matroesjka, a cartoon character of Barbamama, and/or the role of a mother at home. This ambiguity could hinder the further knowledge mapping and transfer, resulting in reduced consumers’ comprehension.

Different from category-based knowledge transfer that encourages extensive knowledge transfer from the existing product category, analogy-based knowledge transfer facilitates only a subset knowledge transfer from the source category (Gregan-paxton & Moreau, 2003). In the example of smart home system “mother,” within the role of a mother at home, only the characteristic of knowing situation at home is transferred to the smart home system. Other characteristics are not transferred, such as taking care of every family member. This specific transfer can help consumers comprehend the innovative benefits of a RNP. However, the success transfer of the knowledge also depends on consumers’ ability of recognizing similarities and mapping the corresponding knowledge into a RNP. Consumers may encounter difficulties in identifying the similarities between a source and a RNP (Gick & Holyoak, 1983). In this case, the presence of a clarification that states the
similarities between a source and a RNP can be helpful.

**Designing product appearances to facilitate consumers’ external learning**

In addition to stimulate consumers’ internal learning through making use of stored knowledge, marketers can facilitate consumers’ external learning of RNPs. Consumers are exposed to different external sources, including advertisements, product demonstrations and RNPs themselves. Therefore, appearance of RNPs can serve as a source for facilitating consumers’ external learning. Specifically, product appearances can facilitate consumers’ external learning through directly communicating innovative technology integrated in RNPs and influencing the congruity between product appearance and innovative functionality of RNPs.

**Product appearance as an information carrier to communicate innovative technology directly**

Because RNPs often integrate highly innovative technology, consumers may not understand how they function (Hoeffler & Herzenstein, 2011). Product appearances can visually communicate the innovative technology and thereby help consumers understand how RNPs work. For example, different from the common technology of capturing dust by differences in pressures, the handheld vacuum cleaner from Dyson adopts the innovative dual-cyclone technology (see figure 7a), which allows it to provide continuously suction power. To produce airflow and capture dust, this innovative technology requires 15 cyclones that are arranged across two levels on the top of the vacuum cleaner. Rather than hiding these cyclones, this handheld vacuum cleaner directly exposes them and highlights outlines of them with a red line. , whose outlines of each cyclone are highlighted with a red line. This unique design can help consumers notice the innovativeness of the adopted technology and learn that this innovative technology is different from the ones they already know. Moreover, in combination with illustrations in the advertisement (see figure 7b), this design can directly communicate the innovative technology: how air flows are generated in each cyclone and how these air flows come together to provide suction power. In this way, consumers can gain a subjective comprehension of how this innovative technology works, and they can become more convinced of the benefits of the innovative technology.

![Figure 7a. Dyson handheld vacuum cleaner.](image)

![Figure 7b. Snapshot of an explanation of the technology.](image)

Visualization is an effective tool to help people learn (e.g., flowchart, illustration). Designers can visualize how complex innovative technology works while designing
product appearance, to simulate consumers’ learning of the innovative technology, which could lead to an enhanced consumers’ comprehension. Different from strategies to facilitate consumers’ internal learning, using such visualizations to facilitate consumers’ learning does not rely on consumers’ current knowledge storage. However, comprehending the innovative technology based on the visualization may require consumers’ imagination. According to the description of the innovative technology, consumers need to imagine how it works based on the visual clues on the product appearance. Sometimes, it can be difficult for consumers. Thus, certain aids can help consumers’ imagine of the innovative technology (e.g., the line drawing in figure 7b).

Product appearance to trigger congruity with the RNP’s functionality

Consumers tend to use product appearance to infer product functionality (Bloch, 1995; Creusen & Schoormans, 2005; Crilly et al., 2004). Previous studies demonstrated that when seeing a novel product appearance, consumers tend to infer that the product integrates innovative technology (Mugge & Schoormans, 2012a, 2012b). When the product indeed integrates innovative technology, a congruity is triggered. In contrast, when the product adopts plain technology, incongruity is evoked. Such (in)congruity makes significant influences on consumers’ processing of product. Specifically, while processing a product, consumers have to process information conveyed through product appearance and the product function information. The (in)congruity influence the processing fluency of consumers’ processing. The congruity can bring a fluent processing, resulting in more positive attitudes (Reber, Schwarz, & Winkielman, 2004). In contrast, incongruity evokes a disfluent processing, which requires ample cognitive resources, resulting in reduced consumers’ evaluation (Van Rompay, Pruyn, & Tieke, 2009; Van Rompay & Pruyn, 2011).

Following this notion, congruity between product appearance and functions can bring a fluent consumers’ processing of RNP, leading to consumers’ enhanced comprehension (Cheng & Mugge, 2015). Specifically, when seeing a visually complex RNP, consumers expect complex technologies adopted in the RNP. For example, a visually complex appearance can signal the innovative functionality of a product (Norman, 1988) and designing visually complex appearance is often used in products that are targeted to professional consumers, such as the professional mouse in figure 8. In fact, complexity is one of the characteristics of an innovation (Rogers, 1995). Thus, a congruity is triggered between a complex appearance and innovative functionality of a RNP.

Designers can design appearance of RNPs to trigger congruity with innovative
functionality of RNPs. Such congruity can influence the fluency of consumers’ learning process, which further influence consumers’ comprehension. Moreover, triggering such congruity does not require consumers’ stored knowledge or ability, which give designers more freedom to design. While designing, designers can consider manipulating certain appearance attributes to trigger congruity between product appearance and the innovative functionality of RNPs. Thus far, novelty and visual complexity have been demonstrated to be congruent with the innovative functionality of RNPs. Additional appearance attributes could exist as well, such as the curviness of the outline of products, materials of product appearances, and certain product personality. For example, the innovative hair dryer from Dyson (see figure 9) integrates the air multiplier technology to provide powerful and stable airflow, sensors to measure the temperature of the hair and microprocessor to give suggestions of the optimal temperature. It allows a fast hair drying tasks without damaging the hair. The product design uses a geometric appearance and metallic surfaces, to convey a high-tech feeling, which together creates an expectation of a highly innovative functionality provided by the product.

![Figure 9. Picture of Dyson hair dryer](image)

**General Discussion**

To facilitate consumers’ comprehension of RNPs, current research mainly focused on developing communication strategies in marketing areas. Limited research attentions have been paid on facilitating consumers’ comprehension through designing appearances of RNPs. This paper fills in this gap by conceptually discussing the designing opportunities for facilitating consumers’ learning through embodying RNPs. More specifically, based on the roles of product appearance for influencing consumer responses (Creusen & Schoormans, 2005; Crilly et al., 2004; Noble & Kumar, 2010), this paper explores four underlying mechanisms through which product appearance can facilitate consumers’ internal and external learning of RNPs.

To facilitate consumers’ internal learning, designers can try to design appearances of RNPs to resemble the prototype from a certain product category. However, a typical looking might make the RNP look the same as other products on the market, which may make consumers wonder about the innovativeness of the RNPs. In this case, the appearance should be looked typical to trigger the category-based or analogy-based knowledge
transfer, but also look slightly different from other products, in order to persuade consumers the innovativeness of the RNP. While designing, designers need to carefully consider this balance.

Furthermore, to facilitate consumers’ external learning, designers can design appearances to communicate the innovative technology directly. When discussing the relationships between product appearance and product functionality, previous studies have focused on the indications that product appearance visually suggest in terms of how to use/operate the product, such as the four semantic functions of a product appearance (i.e., description of a product’s purpose, expression of product qualities, exhortation of requires from a product, identification of product category) (Mono, 1997), and visual clues that should be provided by a product appearance (i.e., affordances that allow certain actions to operate a product, constraints that limit certain actions to prevent improper operation, correspondences between what a consumers’ actions and a product’s visual clues) (Norman, 1988). A research gap exists in designing product appearance to facilitate consumers’ learning of innovative functionality, not merely how to operate a product. This paper fills in this gap by proposing that product appearance can fulfill this goal. However, more research needs to be conducted to empirically examine whether and to what degree the presence of information carried through product appearances can improve consumers’ comprehension of RNPs. Furthermore, a certain optimal amount of visual clues may exist. For example, the full exposure of product internal components can confuse or even terrify consumers, because it is often filled with digital chips. In contrast, the mere presence of several lines to indicate the innovative functionality seem not sufficiently convincing for consumers. Future research opportunities lie in exploring the optimal balance.

While designing RNPs, designers need to choose to use which underlying mechanisms to facilitate consumers’ learning. Each underlying mechanism has its potentials and risks. The decision can be influenced by multiple factors, such as the marketing strategy for the RNP. Moreover, although each underlying mechanism is distinct from each other, designers can combine them to facilitate consumers’ comprehension. For example, designers can design product appearance of RNPs to facilitate category-based knowledge transfer and communicate innovative technology at the same time. Designers can design a product appearance that is typical for the product category to stimulate consumers’ categorization. Meanwhile, designers can still highlight the innovative parts to communicate the innovative technology.

Although the presented design opportunities can be theoretically justified and are supported with some empirical evidence and product examples on the markets, it is important for future research to investigate the optimal situations where product appearance will have the most effective influence on consumers’ comprehension. Certain moderators may exist to influence the effectiveness of the proposed design opportunities. For example, to trigger consumers’ analogy-based knowledge transfer, designers can design product metaphors to embody RNPs. However, visual metaphors, including product metaphors, often carry the risks of allowing multiple interpretations. Thus, to prevent this risk, the presence of a textual clue that states the source of the product metaphor can be helpful (Rompay & Veltkamp, 2014). Therefore, future research needs to explore the optimal situations that ensure the effectiveness of the proposed possibilities.

Author Biography

Peiyao Cheng
Peiyao Cheng is a PhD candidate in School of Design, Hong Kong Polytechnic University. Her research focuses on the influence of product appearance on consumer response to product innovations. She has presented her works in several international conferences, and published her research in Design Studies.

Ruth Mugge
Dr. Ruth Mugge is associate professor of consumer research in the Faculty of Industrial Design Engineering at Delft University of Technology. Her main research focus is on understanding consumer response to product design at purchase and during ownership. She has published her research in such journals as Design Studies, Journal of Engineering Design, Journal of Product Innovation Management, Applied Ergonomics, the Design Journal, and International Journal of Design.

Cees de Bont
Prof. Cees de Bont is dean of school of design and swire chair professor of design in Hong Kong Polytechnic University. His research interests are in the areas of early concept testing of consumer acceptance, consumer behavior, innovation adoption, and networked innovation. He has published in several journals, such as Design Studies, Design Issues, and Journal of Product Innovation Management.
Preliminary Study on the Learning Pressure of Undergraduate Industrial Design Students

Wenzhi Chen, Department of Industrial Design, College of Management, Chang Gung University, Taoyuan, Taiwan, R.O.C., wenzhi@mail.cgu.edu.tw

Abstract

Learning pressure affects students’ learning process and performance. Industrial design education emphasizes that operations on real design problems that have heavy working loads may cause learning pressure. The purpose of this study is to explore the issues causing learning pressure and the pressure management strategies of undergraduate industrial design students. There were 297 students who participated in the questionnaire survey. The main findings are as follows: First, learning pressure includes academic pressure, peer pressure, self-expectations, time pressure, financial pressure, pressure from instructors, external pressure, future career, pressure from parents, resource pressure, achievement, and situational pressure. In addition, the main learning pressure is caused by finance, time, resources, external issues, and future career. Second, the pressure management strategies include problem solving, procrastination and escape, help seeking, leisure, emotional management, and self-adjustment. The most useful strategy for managing pressure is leisure, and procrastination and escape is the least useful strategy. Third, all learning pressures are significantly correlated with procrastination and escape strategy, but the coefficients are low. The results can be a reference for industrial design education and related research.

Keywords: learning pressure, pressure management strategy, industrial design, design education

Learning Pressure

Pressure can defined in many different ways; it can be stimulate, reaction, or process. It causes physiological diseases, behavior problems, psychological distress if the pressure is not released. The students will lead learning pressure through learning process with various factors, such as stress from courses, barrier to communicating with teachers, ineffective learning methods, poor relationships with family and peers, career planning, time management, etc. (Peng, Cherng, Chen, & Lin, 2013).

Learning pressure affects students' learning (Rau, Gao, & Wu, 2008). Appropriate pressure is the driving force of learning, but escape and procrastination in a given situation will lead to...
learning pressure and nervousness, even influencing students’ participation in learning activities (Peng et al., 2013). Early discovery and offering support can help students relieve their learning pressure and to achieve better learning outcomes.

Industrial design students experience many problems throughout their learning process (Chen & Tang, 2013; Yang, You, & Chen, 2005; You, Yang, & Liao, 2007) that may cause learning pressure. When faced with such pressure, students may procrastinate (Lin & Chen, 2013), which may lead to failure, resulting in additional pressure or increasing pressure. Therefore, understanding the learning pressure of industrial design students and explore the factors causing pressure can help students find the resources and methods to relieve the pressure and to improve their learning effectiveness.

The main method for measuring learning pressure and exploring the causes is questionnaire surveys and interviews. For example, Bukhsh, Shahzad, and Nisa (2011) investigated undergraduate students’ learning pressure and the pressure management strategies using a questionnaire survey. They found that students experienced fatigue during pressure. The main causes of pressure were the burden of studying and assignments. The main strategies for relieving pressure were watching television/movies, listening to music, or taking part in other leisure time activities. Sun, Dunne, Hou, and Xu (2011) developed an initial validation of a new instrument to measure academic stress. They conducted a series of cross-sectional questionnaire surveys to examine their psychometric properties and then proposed the final instrument that contains five latent variables: academic pressure, workload, worry about grades, self-expectations, and despondency.

There are many factors that may cause learning pressure in learning industrial design. To understand the learning pressure and the pressure management strategies that students experienced and used, a questionnaire survey was administered to collect the data.

**Research Methods**

**Participants**

There were 297 undergraduate industrial students who participated the survey, including 122 male students (41.1%) and 175 female students (58.9%). There were 150 (50.5%) from public university, 147 (49.5%) from private university, and 177 (59.6%) from university, 120 (40.4%) from a university of science and technology.

**Data Collection and Analysis**

The questionnaire survey was conducted to collect the data. The questionnaire was design according the references and previous research. The categories of questions include the basic information, learning pressure involved in different course types, the issues causing the pressure, and the strategies to relieve the pressure. A Likert scale with five levels was used to measure the degree of the pressure and the efficiency of the pressure management strategies.

All the data were entered into a Microsoft Excel datasheet, then sorted and checked. Finally, the data were analyzed using SPSS software with factor analysis and correlation analysis.
Results

Learning Pressure in Different Courses

A five-level Likert scale was used to measure the learning pressure in different types of courses. A score of 1 represented “no pressure,” and 5 represented “tremendous pressure.” Table 1 presents the results. The average overall learning pressure was 3.33 (SD = .834). The core (practice) courses had the highest learning pressure score of 3.56 (SD = .837), and the score of general education courses was the lowest 2.32 (SD = .963).

Issues Causing Learning Pressure

To explore the issues that caused learning pressure, 50 questions were proposed according the references and previous research. Table 2 lists the mean score (M) and standard deviation (SD) of the questions. A five-level Likert scale was used in the questionnaire. The results demonstrated that the top three questions are: A32. Outsourcing costs are too high, making me experience a great deal of pressure (M = 4.08, SD = .917); A33. The high cost of graduation exhibition makes experience a great deal of pressure (M = 4.18, SD = .895); A43. I experience a great deal of pressure when I cannot achieve my own design goals (M = 4.18, SD = .802). The results illustrated that the high cost for outsourcing and exhibition, and self-achievement requirements cause students to experience considerable pressure.

Management Strategies for Learning Pressure

The 25 strategies used to manage learning pressure were retrieved from previous and related studies and then investigated using five-point Likert scales in which 1 represented “strongly disagree” and 5 “strongly agree.” Table 6 presents the results; there were four strategies with scores higher than 4.0, including B22. Engaging in outdoor activities helps to eliminate stress (M = 4.19, SD = .776); B20. I will use listening music, watching movies, and other leisure
methods to eliminate the pressure (M = 4.13, SD = .856); B2. I will try to overcome my learning difficulties (M = 4.01, SD = .604); and B21. Sleeping can help to eliminate stress (M = 4.00, SD = 1.005).

The Kaiser-Meyer-Olkin Measure of Sampling Adequacy and Bartlett’s Test of Sphericity were used to verify the data for factor analysis. The results shown in Table 7 indicate that the Bartlett’s Test of Sphericity is significant (p < .05). Therefore, the data are suitable for factor analysis.

Correlation between Learning Pressure and Pressure Management Strategies

Figure 1 presents the boxplot of each component of issues caused learning pressure. The top five issues were financial pressure (M = 4.06, SD = .81), time pressure (M = 0.78, SD = .72), resource pressure (M = 3.59, SD = 1.03), external pressure (M = 3.58, SD = .80), and future career (M = 3.53, SD = .88). Figure 2 presents a boxplot of pressure management strategies. The most useful strategies to manage pressure were leisure (M = 4.10, SD = .78) and problem solving (M = 3.91, SD = .48). The least useful strategy was procrastination and escape (M = 2.46, SD = .70).
A Pearson correlation analysis was conducted to explore the relationship between issues causing learning pressure and pressure management strategies. The results are presented in Table 10. All the correlation coefficients were low, but there are still significant correlation pairs. All the issues that caused learning pressure had a significant positive correlation with the procrastination and escape strategy. In addition, academic pressure had a significant negative correlation with problem solving, and time pressure also had a significant negative correlation with help seeking. Financial pressure had a significant positive correlation with emotional management. Future career had significant positive correlation with self-adjustment. Resource pressure had a significant positive correlation with emotional management and a negative correlation with self-adjustment. Situational pressure had a significant positive correlation with emotional management.

Conclusions

Learning pressure affects students’ learning performance, especially in industrial design education where students experience many problems that cause pressure. The purpose of this study was to investigate the learning pressure and management strategies of undergraduate industrial design students.

The results indicate the following:

1) Learning pressure includes academic pressure, peer pressure, self-expectations, time pressure, financial pressure, pressure from instructors, external pressure, future career, pressure from parents, resource pressure, achievement, and situational pressure. In addition, the main learning pressure is caused by finance, time, resources, external issues, and future career.

2) The pressure management strategies include problem solving, procrastination and escape, help seeking, leisure, emotional management, and self-adjustment. The most useful strategy for managing pressure is leisure, and procrastination and escape is the least useful strategy.

3) All learning pressures are significantly correlated with the procrastination and escape strategy, but the coefficients are low.

Industrial design education is a complex challenge. This study is exploratory, and therefore its findings are not conclusive. However, they can deepen the understanding of the design learning process. They could also be applied in teaching and future research. However, there is a continuing need for an adequate theoretical basis for the practical application of design education.

Abstract

Western cultures focus on salient objects and use categorization for purposes of organizing the environment (an analytic view), whereas, East Asians cultures focus more holistically on relationships and similarities among objects when organizing the environment (a holistic view). Previous research has shown that cognitive approaches differ between cultures: European Americans prefer an analytic style, and East Asians tend to use a holistic style. However, little is known about how cultural differences in cognition relate to aesthetic preferences. In this paper, we explored whether cultural differences arise in preferences for products set in matching vs. mismatching contexts. Participants in a laboratory experiment included European Americans and East Asians. Individually, they viewed images of a variety of furniture products (chairs, coffee tables, and floor lamps) and rated their aesthetic appeal. Each product type appeared in three different contexts: matching (target product shown in its usual in-home context); mismatched (target product shown in an unusual in-home context), and neutral (the target product shown on a white background). For both cultural groups, products were judged to be more aesthetically pleasing in the matching than in the mismatched context. However, ratings for products in mismatching contexts were significantly higher among East Asians. Our findings suggest that those with holistic views (East Asians) are more tolerant of mismatches than are those with more analytic views (European Americans). The implications for product and marketing design include greater attention to context presentation.

Keywords: Cultural Cognition, Analytic or Holistic View, Product Aesthetics, Consumer Behavior.

Product design is recognized as a competitive advantage for companies in the marketplace. Since many products have reached maturity in their performance and functionality, aesthetic value now plays a more dominant role in marketing to consumers (Postrel, 2003). It has been shown that product aesthetics influence consumers’ purchasing decisions (Creusen & Schoormans, 2005; Crilly, Moultrie, & Clarkson, 2004; Govers & Schoormans, 2005). In product evaluations, aesthetics are an important dimension that brings pleasure and reflects the individual’s personal values. However, little information exists on cultural differences in aesthetic judgments about products.

Cultural experiences influence how one views and responds to information (Heine, 2012). People in different cultural contexts might perceive a product differently, and as a result may respond differently to representations of products in the marketplace. For example, when a product is sold through the Amazon platform, the identical product is displayed differently in
depending on countries (e.g. Figure 1). On the American site, the displays tend to focus on product features and the product itself without any context of use; in contrast, the Japanese Amazon site draws attention to the use of the product in the context of the home environment. Do these apparent differences within culture reflect aesthetic preferences? In this study, we investigate differences in consumers’ appreciation for products based on their cultural backgrounds.

![Image](image_url)

**Literature Review: Aesthetic Values and Culture**

Leder and colleagues define aesthetics as a cognitive process starting with perception, followed by integration with previous experiences, classification of style and content, interpretation, and evaluation (Leder, Belke, Oeberst, & Augustin, 2004). A more concise definition of aesthetic judgment stresses the sensory (primarily visual) nature of input to judgments (Bloch, Brunel, & Arnold, 2003; Hekkert, 2006; Lindgaard & Whitfield, 2004), where aesthetics is defined as the physical attractiveness of a product mediated mainly by the visual features (Hekkert & Leder, 2008).

Visual perception has been shown to differ based on cultural background (Nisbett, 2003). Westerners tend to be more analytic in their thinking, while East Asians tend to be holistic, attending to the entire field (Masuda & Nisbett, 2001; R. E. Nisbett, Peng, Choi, & Norenzayan, 2001). In perceptual tasks, Westerners are described as “context-independent” because they focus on a salient object rather than its context, whereas East Asians attend to the relationship between an object and its context (Chua, Boland, & Nisbett, 2005; R. E. Nisbett & Miyamoto, 2005). Americans prefer context-exclusive images more than Japanese, consistent with analytic vs. holistic patterns of attention (Masuda & Nisbett, 2001; R. Nisbett, 2003; R. E. Nisbett & Miyamoto, 2005). Masuda and Nisbett (2008) tested the aesthetic appeal of portraits with variations in size of the model and background. They found that Americans prefer
context-exclusive images more than do Japanese (Masuda & Nisbett, 2001; R. Nisbett, 2003; R. E. Nisbett & Miyamoto, 2005). In addition, logos from individualistic (Western) cultures were found to be more angular than those of collectivistic (Asian) cultures, which showed preferences for rounded shapes considered to be more harmonious (Zhang, Feick, & Price, 2006).

These findings demonstrate that cultural differences in perception of visual scenes can affect the way a product is perceived and appreciated. Can culturally-influenced cognition lead to differences in aesthetic preferences? While there are universals of aesthetics in design, aesthetic preferences may not be universal across cultures; instead, people may differ with respect to what they perceive and attend to based on their cultural experiences. However, differences in aesthetic judgments of products based on cultural experience have not yet been adequately addressed. Because cultural differences may impact attention to product images, people from Western cultures may differ from East Asians in their aesthetic judgments about products.

**Research Hypothesis**

By focusing on the product itself, people from Western cultures may be unaffected by the surrounding context; in contrast, those from East Asian cultures may attend more to the relationship between a product and its context. These differences may impact individuals’ aesthetic judgments about a given product. Our hypothesis is that people’s aesthetic preferences will be influenced by their focus on salient objects in the environment (Western cultures) or more holistic view of relationships among objects and contexts (East Asians culture).

**Research Method**

We set out to test this cultural hypothesis by presenting images of products to people and asking for their aesthetic judgments. Within an experiment, we asked people to view images of target products set in one of three different contexts, (1) the target product presented without context; (2) context matched to the target product; and (3) context mismatched to the target product. People were asked for their aesthetic judgments of the product as indicated by a red arrow (e.g., a chair in the cozy studio vs. a chair in a garage in Figure 2). We predicted that Westerners would use an analytic process where judgment of product aesthetics is decontextualized, whereas East Asians would tend to use holistic judgment and therefore be attentive to context.

![Figure 2. The target product presented in three different contexts](image)
Participants

We recruited two groups for this study: European Americans, and East Asians. The European American samples participated through a course requirement at a business school in a large Midwestern U.S. university. The European American group included 171 participants (M_{age}=20.03, 54.9% male, 45.1% female). The East Asian group included 14 international students at the same university (5 Chinese, 5 Korean, and 4 Japanese) who participated for a course requirement in psychology. In addition, ninety-three East Asian students were recruited from a university in Taiwan (for a monetary payment of USD $5), for a total of 107 participants (M_{age}=25.88, 41.1% male, 58.9% female).

Materials

A collection of home products, including furniture (e.g., coffee tables, chairs), kitchen products (e.g., dining table, cabinets), and lighting (e.g., floor lamps, desk lamps) was used in the study. All of the products were designed as objects that fit a specific environmental function and were not portable in use; for example, an armchair set in a living room. We avoided electronic products such as TVs or computers. Each product was shown in a perspective containing its outline, shape, color, material, and detail (e.g. Figure 2a). Three distinct variations of each product image were created: set in a matching context, in a mismatched context, and with no context; for example, the desk chair in three versions is shown in Figure 2.

The Google SketchUP 3D modeling computer program was used to depict identical versions of each product set in three different backgrounds. Every product was shown in a No Context image where it appeared with a white background. In the Match Context images, the background depicted with each product was matched to an appropriate scene (e.g., armchair in a living room, toolbox table in a garage, or dressing table in a bedroom). For the Mismatched Context images, products were placed in within a scene where they do not typically appear; for example, an armchair in a garage, or a toolbox table in a bedroom. The three conditions in the experiment (e.g. Figure 2) -- No Context, Matching Context, and Mismatching Context -- for three specific variants of nine different products resulted in 81 images.

Procedure

At the start of the session, participants were informed that they would be shown a series of products one at a time, and then asked questions about them. Participants were asked to focus on the target product only, and a red arrow appeared in each image to indicate the target product (e.g. Figure 3). Each participant saw nine product types in 3 distinct versions for a total of 27 images: a No Context version, a Matching Context version, and a Mismatching Context) version. For example, one participant saw chair 1 in the No Context condition, chair 2 in the Matching Context, and chair 3 in the Mismatching Context. The context condition was counterbalanced so that specific objects were presented in each context condition equally often across participants. The image presentations for each participant appeared in a randomized order.
We asked participants to answer five questions for each image as our dependent variable. The first question was an aesthetic judgment of the product: “Do you think the product is beautiful?” The second question assessed liking for the product: “Do you like the product itself?” The third question, “How well do you think the product fits into this context?” was a manipulation check to ensure participants perceived the intended mismatch and matching contexts. The fourth question, “Do you like the product in this context?” assessed product liking within matching and mismatching contexts. The final question, “Overall, do you like the whole picture?” assessed general aesthetic preference. Participants answered each question on a 7-point scale using a slider operated with a mouse to indicate the degree of their preference (1, Not at all to 7, Very much). At the end of study, participants completed a demographic questionnaire asking about their age, education, occupation, race, parents’ race, citizenship, duration of living in US, location of birth, and English language ability.

![Figure 3. An example of target product (a chair) shown in a matching context with the rating screen.](image)

**Results**

**Manipulation check**

We used the third question for each image (“How well do you think the product fits into this context?”) as a manipulation check. As expected, the Mismatching Context images were rated lower ($M = 2.40, SD = 1.46$) than the No Context ($M = 3.82, SD = 1.57$) and Matching Context images ($M = 4.54, SD = 1.69$). Across participants, these differences were significant, $F(2, 552) = 680.84, p<.001$.

**Product Beauty**

Responses to the first question, “Do you think the product is beautiful?” were analyzed in a 2 (culture, within-subject) X 3 (condition, between subject) Mixed ANOVA. There were main effects of culture $F(1, 276) = 34.58, p<.001$, and condition $F(2, 552) = 34.21, p<.001$ (e.g. Table 1). There was no interaction between culture and condition, $F(2, 552) = .79, ns$. East Asian participants rated product beauty significantly higher than European American participants in all three conditions; specifically, even when a mismatching context, East Asian participants rated beauty higher ($M=4.10, SD = 1.13$) than European American participants ($M=3.31, SD = 1.13$).
However, all groups rated the Matching Context condition highest, and then No Context, then the Mismatching Context condition.

<td>4.41**</td>
</tr>
</tbody>
</table>

** indicated significantly greater between East Asians and European Americans at p<.001
European American sample size, N = 171
East Asian sample size, N = 107

**Product Liking**

The second question, “Do you like the product itself?” showed very similar results. These two variables were strongly correlated, $r(353)=.91$, $p<.001$, where the more beautiful the product, the more people like it. A main effect of culture ($F(1, 276) = 9.955, p<.005$) reveals that East Asians liked the products more, and that both groups preferred products shown in matching contexts, $F(2, 552) = 39.606, p<.001$. There was again no interaction between culture and condition, $F(2, 552) = 1.129, ns$. Collapsing the product beauty and product liking judgments shows a main effect of culture, where East Asians rated the aesthetic judgment of target object higher than European Americans (e.g. Figure 4).
Product in Context Fit

The third question, “How well do you think the product fits into this context?” showed a main effect of culture, $F(1, 276) = 43.426, p<.001$, where East Asians ($M=4.01, SD = 0.75$) rated all images higher on average than did European Americans ($M=3.35, SD = 0.60$). A main effect of condition ($F(2, 552) = 495.354, p<.001$) indicates that product matching context ($M=4.61, SD = 0.06$) are rated significantly higher than in mismatching contexts ($M=2.44, SD = 0.05$). In addition, there was an interaction between culture and condition, $F(2, 552) = 19.918 , p<.001$ (e.g. Table 2). East Asians ($M=4.71, SD = 1.08$) rated products higher in matching contexts than did European Americans ($M=4.42, SD = 0.95$), and East Asians rated mismatched products’ “fit” higher ($M=3.11, SD = 1.29$) than European American ($M=2.00, SD = 0.66$). These findings suggest that East Asians tolerate mismatches in product context more than European American, even those in a mismatched environmental setting.

</tbody>
</table>

** indicated significantly greater between East Asians and European Americans at $p<.001$

European American sample size, N = 171
East Asian sample size, N = 107

Product in Context Liking

Ratings for the fourth question, “Do you like the product in this context?” also showed that a significant difference between East Asian ($M=3.95, SD = 0.08$) and European American ($M=3.26, SD = 0.06$) ($F(1, 276) = 44.386, p<.001$). A main effect of condition ($F(2, 552) = 466.364, p<.001$) indicates that all three groups prefer products in the Matching Context ($M=4.46, SD = 0.06$) to the Mismatching Context ($M=2.43, SD = 0.05$). Overall, people liked the product presented in an appropriate context rather than an inappropriate context across cultural groups. However, there was also an interaction between culture and condition, $F(2, 552) = 16.329 , p<.001$. The pattern shows that European Americans ($M=1.97, SD = 0.667$) rated products in Mismatching Contexts much lower than East Asians ($M=3.07, SD = 1.31$) (e.g. Figure 5). East Asians preferred products presented in matching contexts, but also show greater appreciation for products in mismatching contexts than European Americans. These results suggest East Asians have a broader acceptance of a product’s context, and view the product as “fitting” the context even though they also acknowledge the mismatch (in question 3).
Overall Liking

The last question assessed general aesthetic preference: “Overall, do you like the whole picture?” There was a main effect of culture $F(1, 276) = 19.559, p<.001$, where East Asians ($M=4.07, SD = 0.09$) like the products more than European Americans ($M=3.57, SD = 0.07$) across all three match conditions. All participants liked the product in the Matching Context condition ($M=4.55, SD = 0.06$) more than mismatching condition ($M=3.10, SD = 0.06$), $F(2, 552) = 280.662, p<.001$. In addition, there was an interaction between culture and mismatching condition, $F(4, 552) = 5.207, p<.005$. While both East Asians ($M=4.65, SD = 1.14$) and European Americans ($M=4.37, SD = 1.00$) preferred products in matching contexts, East Asians ($M=3.37, SD = 1.32$) liked those in mismatching contexts more than European Americans ($M=2.80, SD = 0.91$). This suggests East Asians had a higher tolerance of contextual information, whether in matching or mismatching context. This high tolerance of mismatching contexts for East Asians only may reflect the holistic preference common among East Asians.

In sum, the results show people prefer products presented in matching contexts. The product fitting into a context is judged to be more appropriate, and aesthetic judgments are higher for both groups. However, East Asians appear to tolerate mismatching contexts more than European Americans. They rated products in mismatching contexts as having a better fit and liked them more than did European Americans.

Discussion

This study investigated aesthetic preferences in light of potential cultural variations in cognition. Previous studies have shown cultural variation in attention within images, where
Westerners (European Americans) use an analytic pattern of attention and are more likely to focus on salient objects, while East Asians tend to use a more holistic pattern of attention and to include context in their focus. In this study, we extend these findings to the domain of product aesthetics, and hypothesize that East Asians tend to use holistic judgment of products, whereas Westerners tend to decontextualize their aesthetic judgments by focusing on the target product without regard to context. Following the predicted cultural differences, East Asians are more tolerant of product presentation within mismatching contexts.

The results of this study demonstrate that people prefer a product presentation in a matching context, and even without context, to products shown in mismatching contexts. Presumably, the mismatching contexts pretended to be confusing to people, for example, the unusual image of a floor lamp set in a garage was viewed as “out of order” or unfamiliar by participants. However, cultural differences moderated this pattern: East Asians showed higher perceptual tolerance for products shown in mismatching contexts compared to Westerners. East Asians responded to the mismatch of product to context with higher aesthetic preference judgments. In other words, East Asians accepted mismatching presentations and showed high product liking even when they perceived mismatching contextual information. In contrast, Westerners had lower liking for mismatching contexts, and had more negative aesthetic responses for products with mismatching contexts.

These cultural differences are consistent with previous research (Masuda & Nisbett, 2006) where East Asians were shown to be more sensitive to the environmental context of focal objects in visual scenes. In those studies, European Americans attended to a focal object (such as a fish) and failed to attend to the contextual setting (the background information). Since Westerners appear to be context-exclusive, and East Asians appear to be context-inclusive, these cultural differences in attention, liking, and aesthetics may be important to consider in the design of products and marketing. People are exposed to visual representations of products both within and outside of their context of use when making purchases; for example, a row of coffee pots in a store display may highlight the focal product within a mismatching setting (a shelf) compared to a display kitchen with a single coffeepot. This difference in context displayed may appear in physical settings, catalogs, online listings, and product advertisements.

Cultural sensitivity to product context may be evident in the displays in current use that are designed within a single dominant culture. For example, Amazon’s U.S. site lists products individually with no context, while the Japanese Amazon site shows products within relevant scenarios or contexts. This study appears to be the first to establish cultural differences in product liking and aesthetic judgments based on product and context match. Our results demonstrate that aesthetic judgments and liking for products are also affected by cultural influences. It is important to examine underlying psychological mechanisms that may explain how these variations in aesthetic preferences arise. Cultural patterns may reveal how aesthetic sense develops as people deal with the demands of surroundings, attention, decision efficiency and aesthetic gratification, and may account for the strong association between beauty and liking.

**Contribution**

This study identifies an important factor in the design of products and marketing as the
globalization of commerce extends the sale of products to different cultural areas. From the design perspective, this study provides guidelines for product designers and marketers for considering cognitive differences originating in different cultures. While all groups preferred products presented in matching contexts, East Asians were more tolerant of a mismatching context. For example, Westerner shoppers would be preferred a lounge chair displayed in the living room or without any scene-setting, whereas, East Asian shoppers would be not only preferred the same lounge chair displayed in the living room but also tolerant of the chair displayed in the mismatching scene such as a garage. The present study examines cultural differences in product preference may illuminate why current retailers have developed their cultural styles. In addition, this study also extends existing knowledge about cultural differences in attention to focal objects and contexts (Nisbett & Miyamoto, 2005) to the experience of aesthetic preferences, and expands our understanding of differences in cognitive processing based on culture.

One limitation to generalizing these findings is that this study was conducted in a laboratory where presented participants with product images. The impact of product and context fit may also be influenced by other factors when outside of the lab. Another limitation is that the aesthetic judgments collected were quantitative rather than qualitative in nature. Actual purchase decisions would be more important to show the influence of contextual information in product liking. Further research is needed to explore the connections between product aesthetics and cultural psychology.

The implications of cultural differences in psychological processes may help to account for preferences in consumer behavior, marketing, and product design practices. Presently, the importance of design aesthetics appears greater than ever as more options compete for consumers (Postrel, 2003). Understanding the roots of aesthetic preferences in cultural experiences is important in order to understand the diverse marketplace.

Finding the Expectations of Smart Home and Designing the Meaningful Technology for Delivering Customers’ Satisfaction

Yaliang Chuang, Eindhoven University of Technology, Eindhoven, Netherlands, y.chuang@tue.nl

Yu-Shan Athena Chen, Eindhoven University of Technology, Eindhoven, Netherlands, y.s.chen@tue.nl

Abstract

Smart home is becoming a focus in both literature and product development practices. The current study employed a human-centered design approach to understand users desires and expectations from their living context. Six critical themes were developed via in-depth interview, field observation, and data analysis. They are house as a supportive friend, atmosphere generator, theme songs for every moment, coordinator and reminder, life memory collector, and routine builder for young generations. Those concepts were partially integrated to define the value proposition for the target user group of parents with young children. This guides the design ideation and video prototyping to illustrate the user experiences. Through a focus group discussion, the design concepts were validated with six potential customers. The results also show that the design concept has the potential to motivate children’s behaviors, help to build their routine, and has the flexibility to fulfill different needs toward the changes of the family’s life cycle.

Keywords: Smart home; human–computer interaction; Internet of Things; contextual inquiry; concept design.

Introduction

In the past decade, we have seen the connected technology became an important material and feature of many products. It transforms and upgrades the mundane objects as a kinds of smart things. With the maturing infrastructure of internet and computing capabilities, we are surrounded by enormous services that provide needed information or assistance to support our activities in the virtual spaces and/or physical world. One of the application areas is the smart home. The discussion has attracted much attention in the public press (Manjoo, 2011), marketing media (Higginbotham, n.d.), and academic research (e.g., Brush, et al., 2011; Costanza, et. al., 2014; Dixon, et. al., 2010; Yang & Newman, 2013). However, it did not become a field of research until related technology emerged in recent years (Mennicken, Vermeulen, & Huang, 2014), especially the Internet of Things (IoT). The smart home is no longer merely prototypes under evaluation in laboratories; on the contrary, we have recently seen more and more systems and products demonstrated at the Consumer Electronics Show and sold on the market. However, it was found that very few of products were ready for customers to enjoy the benefits of the innovations in many consumers’ review (such as Higginbotham, n.d.; Mennicken et al., 2014). Even for the people who understand the general sense of a novel
technology, they still encountered many frustrations and questioned the advertised benefits to their lives after using the products for a while (Rodden, et al., 2004; Takayama, Pantofaru, Robson, Soto, & Barry, 2012). Mennicken et al. (2014) thought that this gap was due to the tech-centered approach applied by the majority of designers and researchers. There were very few studies investigating meaningful technologies that translate into a sense of satisfaction (Rodden, et al., 2004).

In this research, we utilized the human-centered design approach to investigate different users’ needs and desires in their everyday lives and understand their expectations of smart home. We started with the contextual interviews and home visiting with ten families to understand their daily rituals and unmet needs, including two design students who live in a shared apartment. We also asked the two designers using cultural probes to collect meaningful objects from their living environments and imagine the smartness they want to added to the artefacts. Through analyzing the observations with theme analysis (Braun & Clarke, 2006), we identified six main insights from their expectations, including House as a Supportive Friend, Room Atmosphere Creator, Give me Theme Songs for Every Moment, Coordinator and Reminder, Life Memory Collector, and Routine Builder for Young Generations. We then compared those ideas with the available products on the market and chose the family with small children as the targeted user because it implies distinct users’ needs and potential marketing opportunities. In the follow-up design process, we used sketches, acting out, and storyboards to develop the product and system. The final concept was the young children’s companion that could guide them to build their routines synced with the family members through their daily activities, such as role playing or bedtime story telling, etc. The tangible doll could also collect the child’s data for helping parents diagnose the problems (such as nightmare) and adjust the environment or day activities to solve the troubles. Finally, we used the video prototyping to illustrate the possible future scenarios for a small family with a young child and recruited six parents to evaluate the concept through a focus group discussion. The result shows that our design concept could not only facilitate the parenting tasks with synchronized routines, but also help to initiate much more intimate interactions with their children. This feature also opens up the possibilities to release the tensions in dealing with the children’s irregular routine and promote harmonious relationships afterward. The main contributions of this study are two folds. First, we demonstrated how to conduct the contextual inquiry (Holtzblatt, 2005) to explore people’s living experiences and understand their expectations of smart home. Second, we showed how to illustrate the user experiences of future technologies with video prototyping (Greenberg, Carpendale, Marquardt, & Buxton, 2012) and use the result to gather target customers’ feedbacks on functionalities and marketing strategies. That new knowledge and methods could lead designers to define and validate meaningful value propositions at the beginning of product development. This will guide them to generate ideations that could deliver specific benefits for the customers.

Related Works

Since Jim Sutherland built the home system (Echo IV) for helping him and his family manage their daily expense in the 1960s (Spicer, 2016), there have been many concepts of smart home developed. One of the important applications is the home security. In average, a burglary takes place every 141 seconds in the U.S. (iControl, 2015). The connected devices and cameras could help to monitor the house and provided the inhabitant's peace of mind. Energy saving and comforts are
the other two common topics related to smart home.

Besides those developments in technology, there also are several design studies that used interviewing and anthropology approaches to understand people’s real experiences of living within a smart home (e.g., Brush et al., 2011; Rodden et al., 2004). Overall, there still are several gaps between customers’ expectations and the smartness of the home system. For example, in the House_n project developed by MIT (2006), there were more than 300 hundred devices embedded in the environment. Although it was a research prototype, the ubiquitous computing concept has been evolved as the main design pattern for system development. In nowadays, it is common to see dozens of tiny devices disturbed around the house in many smart home systems. Gartner (2014) even predicted that a typical family home could contain more than 500 smart devices by 2022. As the number of devices increases, it brings several usability issues of manageability and the user experience challenges in providing flexibility to fit the interactions to their activities.

Beyond those above-mentioned considerations on the system aspects, there also are several design challenges that the design researchers could make contributions. First, regarding the historical development of technology, the majority of the researchers adopted a tech-centered approach (Mennicken, Vermeulen, & Huang, 2014). On the contrary, the user-center design approach could guide the development team to investigate user needs and use the findings to define meaningful technologies that could provide a sense of satisfaction (Rodden et al., 2004). For instance, Lee, Davidoff, Dey, & Zimmerman (2008) focused on the dual-income family with children. They used contextual methodology to understand the inhabitants’ routines and daily activities. Through the qualitative investigations, they pinpointed the frustrations in having the control on their lives, especially the planned tasks related to their children, such as the preparation of school activity or the arrangement of whom to pick up the children. As a result, a smart home that could facilitate the communications among the family members and provides solutions for unexpected situations was proposed in their research. In this case, it was demonstrated that design researchers could play an important role in gaining the better understanding on users’ real problems and provide potential solutions without informational complexity (Yang & Newman, 2013). The most important one is to define clear value proposition from the users’ perspectives and promote its benefits toward the customers’ lives (iControl, 2015; Osterwalder, Pigneur, Bernarda, Smith, & Papadakos, 2014).

**Methods and Participants**

In order to get various inspirations from different compositions of family, generations, and life styles, we recruited diverse user groups for conducting the contextual studies through sampling the participants from the mailing list of a cooperative organization of homemakers in Taiwan. We also used a screening questionnaire to find diverse candidates living with their family members or friends. Finally, three males and seven females who agreed to our home visit were recruited. Eight of the total ten participants were parents, while the other two interviewees were students lived in a rental apartment shared with the other students who majored in different disciplines. The interviewees’ ages ranged from 20 to 60. Their family members or friends were encouraged to join in the conversation when we were interviewing the participants. All of the participants’ housing type was apartment, which is the most common housing type in Asia. The floor space was between 712 and 1300 square feet.

During every home visit, we carried out a semi-structured interview with the participant
(sometimes together with their family members or roommates), and took a home tour with them (Holtzblatt, 2005). In the interview, we followed a script that is focused on understanding 1) basic information about the inhabitants, 2) their daily routines, activities and rituals, 3) some interesting events in the most recent three months, 4) their parenting experience, 5) social interactions, especially the differences or conflicts among them with the other inhabitants, and 6) their opinions and wishes of smart home. In the home tour, we asked the participants to show us the most valuable things (especially electronic devices) and tell us the stories behind their selections. Through asking and discussing the details of the stories with them in the living context, we identified several values that were essential for the customers. The interviewed were transcribed and accompanied with observation notes and photo images for later analysis and discussions in the research group.

Findings

By using the theme analysis (Braun & Clarke, 2006) approach to analyze the data collected from the user interviews and visits, we identified six themes that imply important user values and unmet needs. In this section, we will explain those topics individually and envision some ideas with smart technologies; however, some of the themes overlap and should be taken into account together. The six themes are as follows:

- **House as a Supportive Friend**: When people are lonely or ill, they often feel helpless and desire to receive warming caring or greetings. We found this need strongest for the two students who share the department with the other roommates. Although they live together, however, because they are not as close as family members, they rarely share personal annoyance with the other people. To fill the gaps, the house might be able to act like a friend or mediator in providing caring interactions or asking helps from the other users when the inhabitants show some cues. How might we add emotional intelligences to enable the house fulfill people’s social needs?

- **Room Atmosphere Creator**: It has been found that a pleasant setting of the environment
could help to improve users’ productivities and engagements. In three of the eight families we visited in our study, we found that many participants tend to use the lighting and music to create specific atmospheres for different activities when they have the equipment. But the selection process was time-consuming and sometimes likes trial and error. By utilizing the new IoT technology, the smart home might be able to learn the users’ preferences for doing specific activities and create proper atmospheres for enhancing their experiences, such as reading, entertainment, or enjoying the social interactions of a party.

- **Theme Songs for Every Moment**: In our field study, we noticed that the teenage generations liked to collect the CD or posters of their favorite artists and sing the songs to express their emotions at the moment or as a daily reflection, especially while taking a shower. The two design students mentioned that when they were thinking design ideas, they usually played specific music for inspiring their ideas. Through the connectivity of the home enchantment system and the abilities in activities detection, the smart home can be an implicit company that could facilitate the inhabitants to express their emotions or to inspire new designs.

- **Coordinator and Reminder**: The chaos was another topic we found from the field study, especially in the double-income families. Although most of the families we visited had a family calendar to schedule shared activities, they still had quarrels about some events that the other member forgot to do what they promised before. This might because the group planning was not synced with their personal schedule or was interrupted by unexpected events or important tasks. With the continuous monitoring technology, the smart home could help to synchronize the inhabitants’ schedules, remind them to do specific tasks, and coordinate with each other. This will help people to manage the complexities and have control of their lives (Lee et al., 2008).

In addition to those desires for emotional caring and living scene generator, we also noticed two other interesting themes from the participants’ parenting experiences:

- **Life Memory Collector**: In our visiting, it was found that there were plenty of photos or souvenirs displayed in the participants living spaces. One special category is the handicrafts made by the children for special events. Although those artifacts are implicit triggers to recall many happy memories in their daily lives, the parents were shouldering the burdens of keeping those handicrafts. Very often they struggled on keeping or throwing the old or imperfect pieces when they clean up the house before the Chinese New Year. In addition, three participants who lived in the rental apartment mentioned that they moved several times in their childhood. Every time they moved, they lost invaluable memories marked on the walls or created within the interactions of specific artifacts. Since the digital technology is advanced in data recording and storage, the future smart home could help people to save the memories and recall the happiness in a more economical and interesting way.

- **Routine Builder for Young Generations**: In five of the six families with toddlers (between 2 to 8 years old), the parents encountered similar frustrations in educating their kids to build their daily routine, especially the bed time and morning rituals. Some parents tried to set the goal with their children and motivate them to achieve it with rewards. However, they said it
did not work all the time and they still have not found the effective solutions. With the ubiquitous technology of smart home, we might be able to create interactive activities that could attract children’s attentions and assist them to create the rituals from children’s perspectives.

**Figure 1. Some of the photos collected in the field studies.**

---

**Concept Design Development**

In comparison above mentioned findings with the related works (e.g. Brush et al., 2011; Chan et al., 2017; Lee et al., 2008; Manjoo, 2011; Takayama et al., 2012; Yang & Newman, 2013), we identified parenting and choose family with young children as the target users for design. We then organized two workshops to extract the high-level values and generate design concepts on smart homes. As a result, we created an <Apps4Home> concept and formulated the following value proposition:

<Apps4Home> is an extensible smart home system likes the modern mobile phone. The advanced feature is the alternative packages designed for specific user needs. For instance, in the <Kids' Edition>, there are an interactive storybook, a multiple function table lamp, and a sheep doll that could detect the child’s activities and change the environment settings automatically. Through incorporating the standard communication protocols, the system could collaborate with the other smart devices, such as Philips Hue, to deliver rich user experience. When the parent uses the storybook for the bedtime, the bed room could be augmented like the summer or winter with the assistance of the lighting and air condition or radiator. Some visual images could be projected on the ceiling. At night, the doll could also detect the child’s sleeping and cooperate with the other appliances to calm her down if he/she waked up from a nightmare. In this case, the system will notify the parent in the next morning.
and suggest a better time to wake the child up by analyzing the sleeping data, checking the parents’ schedule, and the traffic status. With the supports of smart home, parents and children could synchronize their activities and build a shared routine together.

The <Apps4Home> also provides an App ecology platform. Developers could utilize the IoT technologies to build bundled applications of tangible devices and software to solve specific users’ needs and provide excellent customer experiences.

In the second workshop, we invited three engineers and six designers to generate ideas that can fulfill those high-level requirements. To guide the brainstorming, we first identified three personas of the double-income family from our first user study. The parents are 35-45 years old and the children are aged from newborn infant to seven years old. During the ideation process, some photos selected from those collected from the home visits were used to help them focus on user needs and inspire interesting concepts. We then used the storyboard to visualize how could those designs be used in their daily lives. In the scenario shown in Figure 2, the doll played as an avatar to be played with the child and detect his/her activities. It also communicated with other machines to provide dynamic services. For example, during storytelling time, the avatar would help to enhance the ambiance by selectively collaborating with the air condition, spray, projector, and speakers to simulate the world of the story. This could enhance the storytelling and initiate the communications between parents and the kids. Since in most of the families, the story time is highly demanded by the children, we assumed that the integrations of interactivity and intelligence could effectively trigger the young generations to follow the parents’ requests in time. For instance, the parent could restrict the storytelling to a specific time. If the children delayed triggering the function, they would miss the new story or unable to experience the augmented versions.

![Figure 2. The Bedtime Ritual for Kids scenario.](image)

**Concept Video**

To evaluate the concept in advance, we used video prototyping (Greenberg, Carpendale, Marquardt, & Buxton, 2012) to illustrate the interactions and user experiences. This is not only a design activity that turned the conceptual idea into a visual demonstration. It is also an ideation process in developing the details of designs during the film making. For example, we not only created the
tangible prototypes specified in the storyboard but also made a simulation system on the mobile phone. The concept video can be accessed via https://youtu.be/I7VrsyqMnkU.

Comparing to physical prototyping, the use of video prototyping enabled us to demonstrate the designs of user experience with an easily understandable format. It also assisted designers to explore the various possibilities in creating the human-system interactions. One example was in the nightmare scene (shown in Figure 3). The avatar was able to sense and monitor the child sleeping. When he/she unexpectedly woke up from a nightmare, the avatar could trigger specific lighting and sound (e.g. parents’ voices or soft music) to comfort him/her. This could probably help to guide him/her into sleeping again.

Figure 3. The concept of calming down children in midnight.

Design Evaluation

In order to understand the customers’ feedback toward our design concept, a focus group discussion was organized. Six parents (one male and five females, aged 36 to 44) who have children younger than 8 years old were recruited from the authors’ social network. During the discussion, we first led them to talk about their parenting experiences and challenges or frustrations, including morning rituals, daily routines, bed time story, and sharing home chores. Although none of them participated our first contextual study, their experiences were consistent with the observations reported in the Findings section. Three of the participants shared their frustrations in synchronizing the children’s routine to the parents’ when they were younger.

The concept video was then presented and the facilitators introduced the concept of smart home and the four main functions of this concept, including: (1) storytelling, (2) atmosphere generated along with the storytelling, (3) accompanying and comforting children during sleeping, and (4) dynamically waking the kid up based on his/her sleeping in the night. Overall, the participants appreciated the user experience and its abilities in facilitating the parenting. Since the kit provides many interactions between the children and the environment, they could learn to have good behaviors in order to get good response from the system. The integration of storytelling could also provide a mechanism to have the children keeping on the schedule in a playful way. Although only two parents shared the experience about their children’s nightmare, they found it would be a useful application if the system could detect it and bring them to dreams automatically.

In addition, we also discussed the marketing settings with the participants. They thought that US$100 could be the reasonable price for a doll and storybook. Two parents thought that the products could be modularized and sold with alternative packages to fit the different life cycle of
the families. When the novice parents has a newborn infant, the physiological monitoring function might be most desirable. However, parents with a toddler would expect divers experiences on storytelling. This suggestion also opens up a possibility in creating long-term customer relationship through the extensible platform. The firm could provide subscription services to customize the functions for parents whose children are in different developmental stages. The <Apps4Home>(Kids’ Edition) could even play as a companion to capture the growth of their children, save their memories and recall the happy moments for some specific events in the family. Together with the participants’ ideas, we envision that this design could not only facilitate the parenting tasks and enhance children’s learning experience, but also lead to more intimate parent-child interactions and harmonious relationships.

Conclusions

Research on the smart home presents several challenges to both design and the innovation of technology. To explore possible opportunities, we conducted a series of contextual inquiries to learn about domestic routines, user needs, and important values. We identified six themes and integrated some of the expectations to define the value propositions. Systematic design approaches were used to generate a hundred ideas with multidisciplinary brainstorming workshops. A concept video was produced to envision the user experience, system functions, and customer benefits. The film was also served as an effective validation tool used in the focus group discussion with six target customers. Through the discussion, we confirmed the design concept and identified advanced features that could help to create a sustainable business model and deliver customer satisfactions.

Prototyping the not-yet-existing for research and innovation: a possible process model for design research.

Juan de la Rosa, Universidad Nacional de Colombia, Bogotá, Colombia University of Illinois at Urbana-Champaign, USA; Institute of Design, IIT, Chicago, USA. jadelarosam@unal.edu.co

Abstract

Design argument and ability to recognize complex systems (Rittel & Webber, 1973) and find a way to modify them, has led other disciplines to try to understand design process and apply it to other areas of knowledge. Creative solutions and ability to innovate (Verganti, 2009) have made design a valuable resource on the contemporary economy. Nevertheless, there is still a polemic about the meaning and model of the process of academic research in the field of design (Muratovski, 2015), the ways in which design research should be conducted and the specific knowledge that is produced with the design research process.

This paper tries to recognize the prototype as a basic element of the process of design, since is connected to a specific type of knowledge and based on that; it also proposes a model of the use of prototypes as a research tool based on four different theoretical concepts which importance in the field of design have been strongly established by different academic communities around the world.

Keywords: Design, Design Research, Prototype, Not-yet-existent, Framework, Design process.

Introduction

This article is intended as a further development of the framework presented by de la Rosa (2016, 2017), and seeks for a more detailed definition of the model presented as a tool for research and the introduction of new theoretical concepts.

The model of use of prototypes as design research objects was supported on three main theoretical concepts (de la Rosa, 2016, 2017) that are commonly connected to the process of design. The first one is the assumption that there is a specific type of knowledge that is generated on the contact with the world and that cannot be established or predicted based on theoretical bases, but defined by our experience of the world (Polanyi, 1958; Polanyi, 1967).

The reaction produced by our contact with the world creates a new tension between the predetermined functional requirements of the artificial world and the specific needs of the users, both the pre-existing ones and the ones that are going to appear in the future as new affordances arise from that contact. That displacement (Simondon, 1958; Latour, 1990; Akrich, 1992) between intent and affordances that produces a constant force of transformation is the second theoretical concept proposed.
Finally, the assumption that design is, by definition, a discipline that seeks for complexity as its desired perspective of the world, and constantly tries to establish the problems as part of a complex system that require a broad perspective (Rittel & Webber, 1973). Based on those concepts, the model presented tries to support and explain how prototypes can be used as probes to test the complexity of the future states of the systems where they are deployed.

This paper seeks for a better explanation of a possible use of this model for research purposes and introduces an initial explanation of the role of time and uncertainty into the model. These concepts are important to define the reason why the use of prototypes becomes a valuable resource when observing complex systems and the variation that they have when new elements are introduced. These ideas are intended as new bases to propose a different model for design research, but since the main idea of the process is the production of design knowledge, or knowledge related to the ways a complex human system can be transformed based on the insertion of designed objects (possible future states of the system and their implications), we believe that the model has also possible uses for design practice.

**Conceptual bases for the model and their role in it**

When trying to understand the possible nature of the knowledge produced by design as a discipline and the role that based on that can be defined for the design researchers, it is necessary to determine the nature of the design process and product. Based on Simon’s (1969) description of design we could recognize two major arguments on the process:

1. Design is about the construction of the artificial, or that, what we have built into the world. Meaning that every design process seeks the construction of a human artifact, either physical, digital or conceptual but a defined human construction.
2. Design is about planning for a desirable change. That means that the argument of design is that we can modify the future on a specific direction by an interaction with the present.

From this definition, we could argue about the existence of a series of intrinsic elements on the model related to time and structure of the system (figure 1),
Based on Simon’s definition we could recognize the idea of a time structure \( (A) \) that is divided into three moments, the existence of a system to be transformed \( (a) \) and a design object or solution to be implemented \( (b) \): Initially, we have a time where design process is happening, that is the present observation of the past state of the system \( (A_0) \). In that, design recognizes a pre-existing problematic condition of the system \( (a_0) \) and the idea of the possible, but not-yet-existing, solution \( (b_0) \). We also have an implementation time \( (A_1) \) where design solutions \( (b_1) \) are deployed into the real system. Most design models will present the implementation or production of the object as the final state of the design process. Finally, we have the real target of the design process: the desired future \( (A_n) \), the one where the system \( (a_n) \) has been transformed by the action of design, and the one that is usually not included on the design process models.

Once these elements are defined as part of the design process, there are a series of questions that arise from this model: If the process of design is supposed to take us from \( a_0 \) to \( a_n \), why do current design models focus their research process on the previous state of the system, rather than desired one? How do we test \( b_1 \) as a viable catalyst of \( a_n \)? How do we produce an image of a complex future system that has been already altered by the not-yet-existing design implementation?

Based on the representation of the model presented based on Simon’s description of the nature of design, we can also recognize three major elements that can be defined based on major theoretical concepts (de la Rosa, 2016). The first major acknowledgement is that, from the perspective of design and of GST, nature is by definition systemic (Maturana & Varela, 1987; Maturana, 2007), therefore, even the more reductionist view of problem solving must be based on the interaction with the multiple factors of the system. In fact, general design process seeks to recognize the complexity of the system (Flood & Carson, 2013) and the problems underneath (Rittel & Webber, 1973).

The complexity of the system for design has an additional element: the fact that we deal with both the current state of the system, the plausible future and the preferred one. The uncertainty of that future state becomes then, one of the main discourses of designers, as a way to explain how the design process is not something that can be automatized or forced; but in
contradiction to that, design practice promotes the idea of a professional certainty over the success of the things that we design to fit on those future-state systems and transform them on a preferred way.

Complex systems are based on the existence of elements that interact (Zeigler, Prähofer, & Kim, 2000), that, from the human perspective, define the existence of actors (both human and non-human) as primary elements of the systems. But actors for design are not stable, they are dynamic and in constant change, adapting to the changes that the environment requires from them and to their needs and desires. Even though we can only see the current state of the system and the past index of it, we know that the system is constantly moving and that what we see is always about to change.

One of those forces that is constantly leading transformation and evolution (Simondon, 1958) of the system is the tension between the needs and desires, the uses and affordances, of the actors inside the system. That tension between the current state and the future desire or affordance has been described on ANT as a ‘displacement’ (Akrich & Latour, 1992; Latour, 2010), a force that is persistently urging us to act.

That tension represents an ever-existing distance between the actors or elements of a system that are connected by their interactions. That is the distance that design always seek to populate, a gap between users and their needs, or their ideas of the future. That tension also defines the not-yet-existing space, the notion of something missing, a constant idea of a better fit with the world that surround us.

Finally, we recognize that the previously mentioned tension, plus the interaction itself of actors inside the system, will produce a transformation of the different elements of the system. That part of the transformation that is based on the interaction of the elements of the system has a significant portion that cannot be formalized or put on a propositional form because is based on tangible experience of the world (Polanyi, 1967).

In his intent to try to define this type of knowledge, Merleau-Ponty, influenced by the work of Heidegger (Gallager, 2010), proposed a concept of ‘embodied knowledge’, as the type of knowledge that requires our body, our hands, to experience the different factors implied on our experience of the world. For Merleau-Ponty & Smith (1996) we are band to understand the world as part of it; our physical existence on the world cannot be eliminated from the way we perceive and understand the world.

As designers, we build meaningful objects for others and try to understand the future state of the object and the system around it. We recognize that we learn about the world as we transform it, as we build on it (Heidegger, 1971). Therefore, it makes sense that at least one type of design research process should involve investigating through actual experiences of individuals of the world surrounding them.
Discussion: General issues of the current models for design process and adaptations for design research

On his intention to reveal the design process with the purpose of eventually being able to automate it, Alexander (1964) proposed the ‘Analysis and Synthesis’ model. This model portrays the design process as three stages (an initial intent based on parameters and requirements, a structured view of the system and the possible solutions run by a program and a final realization where the program has been implemented) and two basic processes (analysis and synthesis).

Later, Banathy (1991) redefined this representation of the process by recognizing that the central stage where ‘the program’ is produced requires a process of synthesis, then, the model became an iterative process of divergence and convergence actions that produces first an image of the future preferred state of the system and then a model of the not-yet-existing solution. That iterative double-diamond (figure 2) model is still used as a foundation for many design process methods (Kumar, 2012).

Both models present significant advances on the definition of the Design Process, especially when it comes to the notion of analysis or divergence, the models present a completely different approach to the traditional engineering process, where the uncertainty only exists at the beginning because even though initial requirements and needs are defined from the beginning, there are uncertain factors that can alter the implementation of the optimal solution.
This concept has been largely described as the ‘cone of uncertainty’ (Bauman, 1958; McConnell, 2006) and applied in many different areas of knowledge. Opposed to engineering and management where the cone is recognized as a model to measure the possible variations of the program based on the existence of external agents that can modify the implementation of an already defined solution (McConell, 2006), design based models (Alexander, Banathy) recognize the concept as a way for the design process to portray the undoubtable variations of a not-yet-existing future; the notion of uncertainty in design models is defined as a double-sided diamond, where the initial requirements are not necessary enough for the designer to understand the problem itself, and there is a constant need to build uncertainty by investigating the complex system where the problem is situated.

While the concept of uncertainty is more commonly used on his convergent way, an actionable principle that portrays an initial high level of unforeseeable factors that alter our ability to achieve a desired goal, other disciplines like meteorology manage this concept as an approach to the future, a way to portray our natural inability to forecast every single factor of a complex system as it untangles. Models of the future presented from the perspective of design (Voros, 2003) also portray the cone as a view of the different outcomes for the future. Voros defines five types of alternative futures on his model: potential, probable, plausible, possible and preferable; these categories are constantly growing as we extend our view of future, the farther we go, the more the system expands.
When considering our ability as designers to consider the repercussions of the implementation of designed solutions, this model allows us to see that the farthest we try to see on time, the more unpredictable those repercussions become. Regardless the fact that this model does not use the term ‘uncertainty’ to describe the enlargement of possibilities as we move through time, we can recognize how the same model of the future can exemplify the correlation between the increment on the level of uncertainty and the distance of time into the future.

![Figure 3. Modification of the model presented by Joseph Voros (2003) to exemplify potential futures.](image)

Looking back to the time instances based on the work of Herbert Simon, that were presented before, we could also establish then, three different stages of uncertainty: an uncertainty of the current system where the initial inquiry could be situated, a stage of uncertainty of the future not-yet-existing designed solution, and a final one, an uncertainty of the future system and the repercussions of the implementation of the design process (figure 4).

This final stage of uncertainty is the less acknowledged and tested by designers, and when recognized through the model of the different futures presented before (Voros, 2003), we could argue that since the implications at the system scale level are usually noticeable on a long-term time-frame, the uncertainty of those becomes higher than usual, therefore, the forecast of the future system becomes less accurate and more complex to determine.

When it comes to the notion of design research in academic communities that believe that there is a certain type of knowledge that can be produced through the process of design (Frayling, 1994; Godin & Zahedi, 2014), the uncertainty to determine system-scale desirable modifications seems to be one of the reasons why the use of common design process models could present several problems when applied as a method to produce reusable knowledge surrounding the subject investigated (de la Rosa 2016, 2017).
Design process presumes the existence of a complex system where the initial problem is situated and embraces the uncertainty of that system and therefore the uncertainty of a not-defined problem. An inverse cone is proposed to build uncertainty, usually by revealing the complexity of the system with a process of ethnographic research into it. The scope of the project determines the complexity that the process is willing to embrace and how detailed or complete is the image of the initial (and therefore past) system that is produced at the end of the analysis process.

The first convergent cone reduces uncertainty by building consensus of what could be the goal of the design process: an image of the transformed future system. A second process of divergence is deployed to search for possible options of designed solutions that can fit into or produce the expected future system.

In this phase, the uncertainty is built on the idea of a possible solution, the designer here presumes the existence of a not-yet-existing tangible solution that can be implemented in the system.

A final process of convergence produces a final model to be implemented. This is the final step of most design models, but the uncertainty of the future system is rarely taken on account or tested.

The not-yet-existing becomes existing and is implemented on the new current system and new affordances are engender by the process of interaction with users.

The tensions produced by the displacement between the new solution implemented and the real needs and affordances creates the space for a new iteration.

Figure 4. Applying the notion presented based on Simon’s definition of design, we can propose three stages of uncertainty
Summing up, that even though Banathy’s model recognizes the existence of a future state of the system, does not provide any views on how to understand or test the functionality of the designed solution to get us there. In addition, common models stop at the implementation process, assuming a positivistic and linear interaction of the designed solution with the system, and do not account for the actual affordances and the unintended transformations of the system. Finally, and probably more important, these models do not seek to produce a reusable knowledge of the future system and its elements and interactions, but a local usable knowledge that is supposed to be embedded on the final solution proposed.

Here is where the concept of displaced prototyping and embodied knowledge becomes an important addition to the design model; since we are trying to investigate on future interactions and responses of the system as we implement design solutions, we should test the system for future responses and review how the peripheral structure of the specific problem can be recognized and questioned to establish plausible and possible variations into the future.

Recognizing that the designed solution is always part of a system and that the distance that every new actor in our socio-technical network has with the rest of us, with the desires of the client, the intentions of the designer, and with the needs of the user give us the chance to produce models of reusable knowledge regarding the principles that define future interactions and transformations of the current system into the desired one. We require new models and methods that allow us to evaluate future interactions and specific knowledge surrounding the objects that we create and design researchers should be able to build those models based on the investigation of real interactions of the system with objects that argue with their users (Galey & Ruecker, 2010).

**Conclusion: a model for design research**

As design researchers, we should be able to recognize and investigate the actual human experience of the world and the parameters that could determine the design process to achieve certain specific transformation for a desired future system. For that purpose, this paper proposes an experimental approach based on the use of prototypes. The main difference with common prototyping processes, is that the one presented here does not intend to validate pre-existing ideas or concept that the designer wishes to implement, but to investigate the structure of the future system as it is being modified by the tangible action of this objects. This action of intentionally producing prototypes as argumentative objects to explore the system might be describe as prototypes as exploratory probes into the future system (Brandt, 2004) or as an object of conversation as defined by Galey and Ruecker (2010), that unveils the possible connections to be created on a real physical relationship with the users and with other objects.

The model then proposes the use of displaced prototypes as research tools. With this model, we stop trying to aim to the ideal solution, and consciously aim to the periphery of the problem on an attempt, not to solve the problem, but to recognize the emerge of new knowledge on the physical interactions of users with it. On a model like this, each instance seeks to increase our understanding of the possible future shifts that this object could generate and in the same process a new understanding of the problem itself (Figure 4).
A research problem is defined around a gray area where there might not be enough knowledge.

An initial process of contextual research seeks to produce enough understanding of emergent trends and possible external factors.

Based on initial research, design produces a hypothesis of the possible desired future system to be tested.

A first displaced prototype is produced and deployed on the system to probe possible reactions of the system.

A systematic deployment of displaced prototypes on the periphery of the problem are produced.

As a result, the researcher produces a model of forecast of the structure of the preferred future system.

We can see that instead of converging into the ‘optimal’ solution, the model seeks for knowledge of the possible ways in which the system can be modified, and the complexity of the system that contains it. (Figure 5).

Common design practices search to close on the problem to generate the most accurate solution to the initial problem. Each iteration is intended to produce a closer view of the optimal solution.

Design research process looks for a model of the knowledge of the future system; with every iteration, displaced prototypes are intended to unveil the nature and the possible ways in which the future system could be reconfigured by design.

Figure 4. When prototypes are aimed to the periphery of the problem we gain a better understanding of the future system.

Figure 5: The role of prototyping on practice based design and in research based design
This model presents a possibility for design research or for design on complex system, and for the different practical applications of those areas, to redefine the way they investigate on diffuse, complex future scenarios, by changing the notion of the prototype from a tool for validation, to an exploratory device that can be consciously deploy by the researcher to produce informed images of the future system.

This type of prototype is not common on regular design practices, and neither it is on design research. Its experimental nature and the fact that, it does not necessarily produce an actionable model or insight for the design process, makes it rarely used; especially since in most cases, prototyping process occurs just once on each stage of the process. Nevertheless, some isolated cases can be recognized when observing distant future innovation on complex, diffuse systems, like the ones presented by de la Rosa, Köhler & Ruecker (2017) as case studies. In those, prototypes were not implemented as validation tools, instead, they were deployed as an intuitive tool to produce a better understanding of a possible long term future on a specific business environment.

One of the possible reasons why this type of prototypes is not more often seen on best commercial and professional practices could be that most of the knowledge produced by these prototypes cannot be easily implemented marketwise. This is because the vast distance between the actionable policies of the company and the possible future scenarios where the image of the system is produced, does not allow for easy, accessible, market actions.

Despite the difficulties that this type of prototype produces for implementation at a professional level, its ability to produce a better understanding of the plausible structure of a preferred state of the system, presents a valuable asset for researchers. Based on the theoretical arguments of previous papers, the ones presented here and the functional traces observed on the previously mentioned case studies (de la Rosa, Köhler & Ruecker, 2017), this paper argument is that this knowledge can generate actionable models of knowledge, that can be used for researchers and system oriented designers to facilitate large scale transformations on diffuse and complex systems.

New experimental research might be required to test this process as a viable action of inquiry for design research, and a possible positive response to this question could represent a need to validate and define it as a standardized possible process to produce designerly knowledge of complex dynamic systems.

Author Biography

Juan de la Rosa
Juan is a full time Associate Professor of design at the Graphic design department of Universidad Nacional de Colombia, teaching on different areas of design: from illustration to interaction design, and recently design theory and research. He was Director of the Design Department at the same university for four years. Before that, he also taught at Universidad Jorge Tadeo Lozano for more than five years.

His current research is on the values that designer unconsciously embed into the things they design and the possible impact that it can generate on public infrastructure. As part of this research, Juan has been working on the development of design research methodologies based on the use of prototypes as research tools.

He has presented and published in several international conferences regarding design research methodologies and the theoretical bases to support new models. He also co-author the book “Methodologies for the design of social poster in Latin America” with two of the major universities in Colombia.
Evaluation of objective and subjective instrument’s behavior in the capture of user’s perception

Introduction

Perception is directly linked to previous experiences, and from there, we select, organize and interpret them. The present research highlights that during the design process, it is necessary that there is an observance of the perception of the individuals that will use or evaluate the products or services offered. **Objective:** Thus, this research has used objective and subjective tools to evaluate the user’s perception in a service field, in order to identify whether these results tended to the same or not, and from this, to identify the problems and solutions to facilitate the user’s understanding. **Methods:** A cross-sectional observational study was performed with 1 evaluation and 2 reevaluations, with 31 users of the physiotherapy service, at the SUS (Health Unic System) outpatient clinic, in which they were initially interviewed and followed by a subjective self-evaluation of force and function and an objective measurement of force at the three moments. **Results:** It was possible to observe that when the user does not know the service and/or the product, the product may not be able to have the correct perception of the product and/or the service. **Conclusion:** This shows how important it is to evaluate the perception of individuals in general, from the user to the objective instrument, so that the project can be developed to meet the needs of the individuals.

**Keywords:** Artifact Evaluation, Design, User Perception, Design Methodology.

Evaluating the perception of users is not a trivial issue, since the 18th century, several researchers have studied this subject, as in the research of the English philosopher George Berkeley (1686-1753) when he developed a theory of autonomous perception, researching the View of man and its components. Its use there is no limit or borders (BURDEK, 2006).

In the process of product development, as example, perception evaluation criteria can be included, which can be divided into three components, subjective evaluation, this is not only a simple answer of yes or no, but an analysis of affections, symbols and semantics of the people who evaluate, therefore, seeking different qualities like, functionality, hedonism, reliability and among other things; The sensory environment through which the product is perceived includes touch, taste, smell, hearing, and vision; And the design element, depends on the complexity of the object and any detail can play a determining role in the evaluation of the product (MONTIGNIES, NOSULENKO and PARIZET, 2010).
In Physiotherapy, the purpose of the evaluation is to gather data about the patient's health status and, as such, to develop a database about the patient, and from there, to plan the program that will be performed, in order to optimize the results. And for this, it is necessary that the professional and the patient have an adequate perception of what is happening, so that feedback is possible and that the planning is as correct as possible (PALMER, 2000).

However, in both design and physiotherapy, analyzing the perception of the users can generate divergences of results, this research seeks to verify the behavior of objective and subjective assessment methods in the capture of this perception.

**Literature Review**

The perception, according to Solomom (1994), is "… the process by which sensations are selected, organized and interpreted", and Churchill and Peter (1995), says "It is the way in which people acquire and store information", and Kotler (1998) states that "It is the process by which a person selects, organizes, and interprets information to create a meaningful picture of the world." However, in 2012, Lanutti et al said that the perception is directly linked to the experiences lived in the past (LANUTTI et al, 2012).

So when an individual observes, buys, and uses a product, various feelings, sensations and emotions arising from the perception and information sent by the object are awakened, and perception is not influenced only by the tactile and visual elements, but also by the unconscious of it, through the lived experiences (LANUTTI et al, 2012).

From this it can be observed that the various definitions and thoughts about perception suggest that it is from this that people will select, organize, interpret, and store information that will be individual, and that will influence the individual when the same comes across Product, because this will arouse diverse feelings and sensations and this will influence how the same will perceive this product. With this it is worth stressing that each consumer will have a different level of perception of the other, as it will depend on how each one receives and stores the information. (LANUTTI et al, 2012; CHURCHILL e PETER, 1995; KOTLER, 1998)

It is now widely perceived that the market is increasingly competitive with the development of new artifacts that seek to meet the needs and tastes of consumers and is a crucial issue in terms of the design of new artifacts or their redesign. It can also be said that meeting these needs can often be seen as an exacerbated generation of demand, but not of necessity, given that it is latent. (PETIOT AND YANNOU, 2010).

As Kimmel (2015) points out, consumers rely heavily on information that surrounds them daily during their lifetime to interpret and even assign meaning to what actually occurs around them. Of course, the perception of product design is, to a certain extent, determined by the prior experiences of users with other artifacts, whether similar or not.

According to Lu and Petiot (2014), the success of a product on the market is determined not only by its technical and objective content, but also by aesthetic, emotional and other experiential factors. In the practice of designing, the development of new artifacts needs to take into account the balance between objective and subjective qualities, between the functionality of technology and emotional expressiveness, in an
attempt to satisfy the demands and desires of potential users. Already mentioned, "individual needs". It becomes imperative to capture relevant information and anticipate users' expectations. The various emotions triggered even by the appearance of the artifact to be acquired can increase the pleasure of buying, possessing and clearly, of using it.

In health, having prior knowledge of health perception, can determine the thinking and action of the population in the face of the health-disease process, and is fundamental for the efficiency of health care and education actions. As a result, there has been growing concern not only with the frequency and severity of diseases, but also with the evaluation of measures of disease impact and commitment of activities, measures of health perception and functionality. (CAMARA, 2012; FLECK, 2000)

When thinking about product development or service evaluation, a concept that will generate great influence during the design process, is the User Experience (UX), which seeks to understand how the user will interpret / evaluate the use and / or The service, as each individual will have a different observance during this process. And UX, can be understood as a flow of feelings, thoughts and actions, and considered unconscious, but it is accessible to those who experience it. (FORLIZZI e BATTARBBEE, 2004)

However, understanding this experience is a critical issue, especially for design, and in recent years there has been a growing interest in designing this experience, and some early efforts to create new theories can be observed. However, little has been done to expand this idea, requiring much more work in order to understand the human experience and the efforts to design for the user. (FORLIZZI e BATTARBBEE, 2004; HASSENZAHL, DIEFENBACH e GÖRITZ, 2010; FORLIZZI e FORD, 2000).

Research Methods

This research is an observational, cross-sectional, descriptive-analytical study that aimed to verify the behavior of the objective and subjective instruments that evaluate the users' perception.

This experiment was approved by the ethics committee of the UFPE on the CAAE number: 45705715.0.0000.5208, Report No.: 1,144,880, project "Evaluation of the Behavior of Objective and Subjective Instruments in the Capture of Users Perception".

The experiment was carried out in a Physiotherapy outpatient clinic specialized in the hand of a Hospital of the public network, between 2015 and 2016. For the selection of the participants was used as inclusion criteria, the participant should present pathology in the hand. Participants who had functional problems due to the consequences of pathologies affecting other parts of the limb, other than the hand (example: elbow, shoulder, etc.), were excluded; The participant presents any pathology that generates functional disability in the hand; And / or present cognitive changes.

This sample consisted of 31 individuals of both sexes, who had several hand pathologies, which showed a decrease in the grip strength of digital pulp-to-pulp tweezers and were therefore performing physiotherapy in the physiological outpatient clinic practice.

Of these 31 individuals, 19 were female and 12 were male, aged 22-78 years, mean age 48.8 and standard deviation of ± 13.97, mostly: (83.9%) right-handed, And retirees / pensioners / home / unemployed (42%), who underwent surgery (61.3%). Of these
individuals, 15 (48.4%) reported some improvement after physiotherapeutic treatment, with an average of 12 (twelve) physiotherapy sessions (standard deviation of ± 24.61).

Two types of instruments were chosen to evaluate the users' perception of the hand force being treated, one performed by the user and another by an objective instrument based on a digital dynamometer built specifically for this experiment.

The first was the subjective User Force Assessment, which consisted of a test, based on Lovett's guidelines, in which classification is based on the individual's ability to perform the movement against or against the maximum manual endurance of the examiner. Being evaluated from 0 to 5, where zero is considered no force and five maximum force, against resistance of the evaluator. (SALVIAN et al, 2012). In this case, the user was asked how much he could quantify his strength on a scale of 0 to 5, when performing the movement.

The second instrument was the Digital Dynamometer Tweezer Pulp-to-pulp. This was a pulp-to-pulp digital dynamometer, developed by the authors of this research, using a microcontroller with an open-source platform, in search of cheapening the manufacturing cost. It is worth noting that the development and choice of this equipment occurred because the laboratory did not contain the digital pulp-to-pulp dynamometer used by the market and to reduce the cost of the research, since this type of dynamometer costs in lathes of US$ 500.00 (EVANS, NOBLE and HOCHENBAUM, 2013, MCROBERTS, 2011).

This technology called Arduino was associated with a force sensor (Figure 1), seeking to measure the strength of the user through this Dynamometer. For this, it was necessary that the equipment was programmed in language in C. And in this programming a scale of 0 to 100 was used, corresponding zero to no force and one hundred to the maximum force. This type of calibration was adopted because it was realized that it was not necessary to have a calibration on an absolute scale because it was simply not relevant to the research, since what was sought was an objective evaluation to evaluate the strength of the individual, with the other evaluation scale.

The equipment consists of a plate with the microprocessor, in which data is stored and generated, in LED lights for calibration, an LCD screen, in which feedback values are displayed in the scale, and a Power source, which can be through a USB power cable or a battery. In Figure 2, it is possible to observe the assembly of the equipment.
Measurements were repeated two more times at intervals of at least one week. Failure to observe a constant frequency between them is due to the fact that in clinical practice the patients do not obey a strict sequence, and the schedules of the professionals, who were very specific.

SPSS 13.0 Software for Windows and Excel 2010 were used for the analysis of the results and all the tests were applied with 95% confidence. The results are presented in table form with their respective absolute and relative frequencies.

When observing the behavior of the instruments used to evaluate perception during the three moments, that is, Assessment 1 (Av1), Assessment 2 (Av2) and Assessment 3 (Av3), in the evaluated hand, it was noted that there was a significant difference in the evolution in the design instrument, which is the Arduino, in which a statistical significance of $p < 0.001$ could be observed, showing that at the end of the 3 evaluations the participants presented an improvement of their condition, since in these instruments, the higher the value, better your recovery condition and strength. Deferred from that observed in the subjective instrument used with the user, in which no significant relevance could be observed. (Table 1)

Discussion

When thinking about user surveys about perception, it is important to use tools that are easy to see but still require visualization knowledge on the part of the user. That is, the user should not only realize, but also understand the information presented. Perception and understanding depend on several factors intrinsic to people, but also the experience of each in the execution of the required task or during the use of a given product (FRAUNHOFER et al, 1994).

When analyzing several studies that used similar instruments, it was observed that in the study by Shin et al (2012), it is noticed that the number of individuals studied, is similar to the group studied in this study, totaling a number of 30 individuals. This study differs from the studies by Ferreira et al (2011), Gonçalves et al (2010), and Savian et al (2012) who studied 199, 15 and 45 subjects, respectively.

As for the age of the groups studied in the several studies, a divergence between the means of age is observed, as can be observed in the studies by Shin et al (2012), Savian et al (2012) and Gonçalves et al (2010). Which had a mean of 27.8 years, 63.5 years and 37.3 years, respectively. This can be justified, because the group studied in this research, is very restricted to hand pathology, and the others are used for strength evaluation in other types of patients, some just to draw a profile, in relation to hand strength, in certain specific groups, such as diabetics and airplane pilots.

When analyzing the sex of the subjects, it can be noted that in the studies of Gonçalves et al (2010) and Savian (2012), a predominance of males is observed, since the groups studied by them are very specific, as pilots of Plane and diabetic, respectively. This diverges from this study, which presented a larger number of women, which is justified by the fact that in clinical practice, the quantitative of female patients is always greater, and this premise is strengthened by the research carried out by the Ministry of Health In the year 2016, which reports that a certain one-third (31%) of Brazilian men do not have the habit of seeking health services, neither to monitor their health status nor to seek help in disease prevention and Quality of life (PORTAL SAÚDE, 2016).
When the user performed the self-assessment of strength, it was not possible to observe evolution in the treatment. This can be justified by the fact that the participants were not able to measure their strength used to carry out the requested movement and did not perform this type of self-evaluation in their daily lives. This result could not be proved by other studies, since they do not use this type of evaluation, but this lack of experience in this type of evaluation, can generate an altered perception of reality, because according to what is thought of perception and Users Experience, this makes all sense (Forlizzi and Battare, 2004).

When compared to the studies by Shin et al (2012), Figueiredo et al (2006), who used a digital dynamometer already used in the market, and this research, it was possible to observe that there was a significant improvement in the evolution of these individuals after the tests, When comparing the initial and final values of the digital dynamometry, in relation to the force. What can help prove that the equipment used in the research even using a different scale may lead to a tendency to show that the results tend to a truth.

At the end, an analysis of the convergence of the results of all the objective and subjective instruments was performed, based on the correlation between the data evaluated in the three moments of the research. And it could be observed that there was no convergence between Force in hand evaluated user x Arduino, which can be justified by the fact that the user does not know how to measure force.

**Conclusion**

When you think about technological development, you see a very fast development, which often generates dissatisfaction in users, due to misunderstandings between designers and consumers about the perceptions of use of the products. And the identification of this user perception has become a major obstacle in the Design process and for the producers (GUO and TIAN, 2010).

And this can also be seen and used in other areas of knowledge, such as the health area, in which the perception of the patient / client / user is of fundamental importance for the development of their condition / quality of life. As can be seen in several instruments used for QOL evaluation, strength, function, among others. As it is also important that the professional use basement instruments to follow the evolution of his patient.

When the experiment was thought of, several ways of evaluating perception and how to evaluate it at different times were thought of when the idea of evaluating the same variable came up in different ways and with different views.

And with this it is possible to conceive the idea that the lack of experience of the individual can lead to misunderstandings and/or misperceptions about its evolution in the treatment, and even a confusion about what is really strength, since according to UX, There must be prior experience in order to have an adequate perception of the product or service that the user uses.

And when the objective instrument was used, the pulp-to-pulp digital dynamometer, developed by the authors of the research, was shown to have a significant improvement in the individual's three moments.
With this, it is concluded that with the data obtained in this research, it is possible to have an idea of how the perception works of individuals who are not familiar with a given situation or product / artifact, but never these opinions and this information generated by it must be Discourse, on the contrary, it is necessary to do more studies with the different types of individuals and their relations of perception that can be used as beacons / tools that assist as decision makers. That is, which leads us to other questions, such as: if the individuals were blind, would there be differences in the results, because they present a much sharper touch?

Abstract

Design is by nature an interdisciplinary, dynamic, and fluid discipline (Cross, 1982; Friedman, 2003). To define what design is has proved to be a very difficult—if not impossible and meaningless—exercise (Friedman, 2000), making also the understanding of the evolution of both the design discipline and practice a complex challenge. A rapidly changing technological landscape increases the breadth of design both in geographical terms and by extending to new domains, merging with different and new disciplines.

Communication Design especially, being closer to the information and the media spheres, is the most sensitive and receptive design area. Communication Design finds online a fertile ground for its growth and developments, thus the online environment and the Web especially can be explored, dug, and mapped as mirrors of that evolution. The aim of our research is to map through the Web the complexity of the intersections between design as a discipline and design as a field of practice. Our exploration and representation of the online design territory covered four online environments: Behance, Wikipedia, Google, and the websites of the top one hundred design universities. The study has been conducted by using digital, statistical, and visualization methods. This exploration seeks neither to confirm theories nor predict the future, rather, it wants to make explicit and observable what Communication Design has become today. It aims to screenshot the state of the art, the emerging paths, in order to understand where and how it is going to develop. The attempt is to make design as a complex phenomenon visible, through the construction of a set of maps and representations for professors, students, and associations. These representations are tools to trigger reflections on the discipline and the profession, bringing a contribution to the experimental research in this field.

Keyworlds: Communication Design, Digital Methods, Web Research, Data Visualization, Design Education

The Internet and the new technologies that have accompanied it have led to new social contexts, new forms of interaction, and new knowledge structures based on speed and change. Social media platforms, especially, have demonstrated considerable growth in the last few years and, thanks to the development of digital methods of research, they can be seen as rich sources of knowledge. According to the Digital Methods Initiative (DMI)—a Web studies research group based in Amsterdam—these platforms can be “repurposed” as rich and easily accessible sources for data that open up hidden knowledge about culture and society. We believe that embracing this approach—widely used in other disciplines such as sociology—also can open up new perspectives to design research, leading to new reflections on a discipline that finds online the most fertile ground for its development.
This paper presents the process and the results of a study that exploits Digital Methods of research to understand if and how a disciplinary and professional complex domain can be explored and represented through the Web. Digital Methods and Data Visualizations are the main methodologies that have been integrated to enable the observation of design as a discipline and a field of practice.

To test and validate a new and different approach to design research that takes advantage of these digital and cartographic methods, is also a goal of the research. The research refers to data and information collected between May and June 2016.

**Aim and Objectives**

This research aims at investigating and mapping what Communication Design is today through the Web, how it appears, and how it is perceived on that venue. The Web thus becomes the exploration field, the focus, and the source of data for this study. The final attempt is to build a useful and accessible tool that could lead to a first orientation on the Web dimension of the Communication Design field. It can also reflect the discipline in its current state, contributing to the orientation of further research activities carried out in this specific area. Thanks to the new research methods and tools developed in the social and cultural sciences and offered through the Web, we can observe the Communication Design area from an unprecedented number of diverse points of view.

The results of this research are not error proof, and the study does not aim at providing a comprehensive representation of the discipline on the Web. Rather, it tests new methods of analysis and new investigation approaches. Therefore, this project doesn’t have the ambition of being considered as conclusive and complete. Rather, it should be considered as the starting point for further explorations.

**Expected results**

The research output has two functions: 1) to support anyone interested in exploring and learning about the discipline; and 2) to create the starting point and the conditions for anyone who wants to engage in this type of research, by providing a methodological basis. Therefore, the attempt is not to deliver a final result but to create a series of maps for students, professors, and associations that will develop their own findings. Moreover, this research could serve, on the one hand, as an input for new reflections on the discipline, and, on the other hand, as a validation output for the future: being able to watch what the design discipline and the profession have become today could facilitate thinking about their future. In the future, having a screenshot of the past could help to make visible the changes that have occurred in this area.

**Research Methodology**

In potential, the Web offers endless ways to do a digital research, also in the specific context of Communication Design. For this reason, it was necessary to narrow the field. Four online environments have been chosen to explore Communication Design, which correspond to four significant points of view to observe the online phenomenon. These environments are:
Behance, Google.com, Wikipedia, and the websites of the top 100 design universities of the QS World University Rankings. The choice of the online environments was a fundamental and decisive step for the research developments, as the *a priori* study of them has been indispensable for understanding the type of data and information to extract.

The research environments have been chosen after several trials. Indeed, the entire research has been conducted with an empirical approach. Initial questions have been constantly defined and then redefined. It has been a research based on experimentation and observation, which has seen lots of back and forth moments. Sometimes these moments corresponded to new questions, other times to new environments to explore. When it was discovered that some paths did not lead to any result, it was necessary to go back and start over (Figure 1).

The research process consisted of these main steps: the formulation of initial questions, data gathering, data analysis, and visual exploration. However, the process was not always that linear. Sometimes it was necessary to go back and reiterate some steps: Initial questions → Data Collection → Redefinition of initial questions → New data collection → Data analysis → Data visualization → New data collection → etc. (Figure 2). Between the initial questions and the data collection, there was always the definition of the methods and tools to collect the data.
This observation has an interdisciplinary nature since it borrows computational, statistical, and representative methods and models. Visualizations, in particular, play a fundamental role. They are used both as useful tools in the process and as communication devices.

Research Phases

In the following sub-chapters, we will explain the reasons why the four online environments were chosen; we will then outline the specificities that could be taken into consideration from each environment for the analysis and show the insights derived from these. The general questions that we sought to answer were: 1. How is Communication Design described on the Web (Wikipedia)? 2. Who are the relevant actors that emerge from the Web regarding this topic (Google)? 3. What can the Web tell us about the academic offer (QS rank—Universities websites)? 4. Who are the designers of today and where are they located (Behance)? It is important to keep in mind that the four explorations have been simultaneously conducted and that they are configured as four separate views, which followed different protocols, methods, and approaches.

Wikipedia

According to Alexa, Wikipedia is the largest free, public encyclopedia, as well as the fifth most visited website of the Web\(^1\). The platform, unlike traditional encyclopedias, works as an open system where anyone is allowed to edit\(^2\). Wikipedia collects more than 44 million articles, and it includes 295 different language editions. When querying Google.com with “Communication Design,” Wikipedia’s definition is the first one to which we have access and this constitutes the importance of its analysis. So the question is: How could this open system be exploited for digital research? What can it tell us about this context of research? Several tools have been developed in order to study this platform. For instance, Contropedia for studying controversial articles or tools such as Manypedia and Omnipedia to compare the diverse linguistic points of view. The questions we seek to answer are: How is Communication Design defined on Wikipedia? Are there different linguistic understandings of the topic? Which concepts emerge among the different editions?

---

1 alexa.com/topsites, accessed on March 17th 2017
2 meta.wikimedia.org/wiki/List_of_Wikipedias, accessed on March 17 2017
The aim of this protocol of research (Figure 3) was to highlight the similarities and differences between each of the language editions of the “Communication Design” page. Firstly, we identified the languages in which the page was available. Consequently, for each page, we scraped the edits’ history page in order to understand the evolution of the articles over time. By using a tool developed by the DMI, Wiki Edit Scraper, it was possible to scrape the complete edit history for the given pages returning some information, such as time and date of the edit, size of the edit (calculated in bytes), comments, and type of user editing (registered, anonymous, or BOT). Other digital objects we analyzed are the internal links of each Wikipedia article.

Internal links have been often “repurposed” for digital research. The same Wikipedia guidelines tell us about the importance of these Wiki objects: internal links should be used to increase readers’ understanding of the topic at hand. The aim of this phase was to investigate different linguistic understandings of the topic. In order to make a comparison, it was indispensable to translate all these concepts in a common language. Through the use of Manypedia, it was possible to scrape these items of information directly in English.
The output of this protocol of research is a set of six visualizations (Figure 4). We present here two of them. The first visualization (Figure 5) represents the article length of each language edition available. What can be seen is that the English article appears as the longest article. The English edition is indeed the Wikipedia’s largest edition, representing about 13% of the total number of articles. The Italian article is instead very short and not really explanatory. For the German and Portuguese versions, Wikipedia redirects instead to other pages, respectively to the “Grafikdesign” page (which corresponds with the English “Graphic Design”) and the “Comunicação Visual” page (which corresponds with “Visual Communication”). This is an important item of information itself because it means that no page called “Communication Design” exists in these languages—as in many others—and that “Graphic Design” and “Visual Communication” are concepts that appear as substitutes for “Communication Design.”
Although the English edition has a content advantage, the other languages can contain unique information. This network (Figure 6) shows all common and unique links of the different language versions of the article “Communication Design.” The network, built with Gephi software, aims to highlight the concepts that different languages mention (Figure 6.1) and the ones mentioned instead by a single edition (Figure 6.2).
Figure 6.1. Focus on common concepts

Figure 6.2. Focus on unique concepts
Google.com

Google is today the leading search engine across the world. It is the first point of access to information and it contains actors that can be analyzed. Mapping who is at the top of Google rank when talking about Communication Design could be a way to understand who mainly talks or is involved with this topic today on the Web. How is it possible to practically collect and organize a quantity of results that are so internally various? And how to take advantage of the rich sources of information such as URLs? Scrapers and crawlers serve as devices capable of bringing order to the Web, as they make it possible to collect and restructure large quantities of data. If with scrapers it is possible to retrieve a list of URLs, with crawl tools it is possible to make the syntax of these URLs a suitable field for analysis (Weltevrede, 2016: 25–51). The web crawler specifically used in this research is Hyphe, developed by Sciences Po’s Médialab. Hyphe allows harvesting of the hyperlinks of a collection of Web pages by performing a series of “crawl jobs.” The typical output is a network of Web entities to be analyzed through network analysis softwares such as Gephi.

This analysis followed the protocol shown in Figure 7. Starting from Google.com, the query used was “Communication Design.” In order to obtain unbiased results, it was important to follow three initial steps: 1. disconnect from any Google account; 2. open a new window in incognito mode; and 3. set “never show instant results.” After this procedure, it was possible to formulate the query and to collect the top 200 results. Once the data set was created, each website was tagged for its nature in order to define the actors. After this step, a crawling was performed for “Communication Design” results. The output of this protocol is a set of three visualizations that allow the exploration of the phenomenon (Figure 8).
“One can profile an actor according to the links it gives and receives” (Rogers, 2010: 224). This network map (Figure 9) is the result of the web crawling performed from the list of URLs obtained from the query “Communication Design.” The red bubbles represent the starting websites, while the orange ones represent the discovered actors, which are those websites that the starting URLs link to. The size of the bubbles represents the in-degree, which is the number of links that each bubble received: the most linked entities correspond indeed to the biggest bubbles.

Figure 9. Network map showing the relationships among actors that emerged from a crawling job of 200 top Google results of the query “Communication Design”

The map provides indications about the actors that appear in the network and about their importance and overall centrality. The largest nodes are “AIGA,” the professional
association for Design, and “Adobe,” the leading developer company of software for Design uses. Social media and other companies such as “Google” have been taken off from the network since they were linked almost with everything, and they made the readability of the other nodes too difficult. The emergent actors have been categorized by type. This way, we could see that most of the results were universities.

**QS Rank and Universities websites**

The world of Design is analyzed here by questioning the state of Design education. The list of universities considered in the analysis was extracted from the QS World University Ranking. By typing the query “top Design universities” on Google.com, the first result was indeed the “QS World University Rankings by Subject.” Highlighting the world’s most prestigious universities through a range of popular subject areas, the QS ranking is the most trusted among the universities’ rankings. Based on academic and employees’ reputations, research impact, and student opinions, the QS ranking has been published annually since 2011 by Quacquarelli Symonds, a company specializing in education and studies abroad. Only in 2015, they introduced the subject of “Art & Design” under the category of “Arts & Humanities.” The questions that led this exploration are: What is the state of Design education? Which are the Design fields existing according to the top 100 Design Universities of the world? What and where are the boundaries among Art, Design, and Science in the Design education field? This analysis compares universities’ Design programs to figure out which are the most frequent disciplines, which are the emerging ones, and if there is a common pattern in education and in the level of specialization of the current degrees.

The data set was created by merging the rankings of the years 2015 and 2016 in order to have a list of the top 100 design universities. Some universities were deleted since they do not offer Design degrees but only Art degrees, a consequence of the wide subject “Art & Design.” The information extracted from each university consisted of a) the names of the degree programs offered; 2) the degree level (we considered only Bachelors and Masters);
and 3) the type of degree (Art, Science, Fine Arts, Design, etc.).

The visualizations created (Figure 11) aim to map the current state of Design in the academic system by showing the diverse types of Bachelor and Master’s degrees existing in the field. The intent is to discover which are the most recurrent programs, offered by many, and which the unique ones; and if universities have adapted to the technology changes that have inevitably affected the Design profession by inserting new programs, or if they are still based on the most traditional ones.

The visualizations (Figures 12–13) show all the Design degree programs existing among the universities considered. The first one represents all Bachelor programs and the second one all Masters. The names of the programs are linked to the universities that offer that specific type of degree. The programs that occur the most are represented with big bubbles while the ones linked to a single university appear as very small nodes. The size of universities’ nodes, instead, indicates the number of design degrees that a school offers, while their central position indicates the fact that it has many degree programs in common with the others. In fact, while the network of the Bachelor degrees tends to be compacted toward a central area, the network of Master degrees loses centrality. In other words, programs at a Master level tend to be more diversified—at least in the way they are designated. So, for instance, the program that, at Bachelor level, in many is called “Fashion Design,” at Master level becomes “Design for Fashion Systems” or “Fashion Design Management.”
Figure 12. Network map of Design Bachelor’s programs and Universities

Figure 13. Network map of Design Master’s programs and Universities
Behance

Adobe’s Behance social network is one of the biggest online communities for creatives. Students, freelancers, and companies use it to showcase their works on a global scale. In 2015, it counted over six million members around the world.\(^3\) In such a well-organized and already structured system, data access is even easier, so we can easily obtain insights from this creative world. By embracing what E. Weltevrede (2016) defines as a “device-driven digital research,” we are able to account for the specificity of the platform and the way information is already structured, in order to derive analytics. The questions we wanted to answer are: Where do the most appreciated designers come from? Who are the UI/UX, Interaction, Web, and Graphic designers? Which other creative fields do they master?

![Figure 14. Communication Design on Behance: data gathering protocol](image)

The platform organizes the creative world through a filter system, which allows searching for a series of variables. There are exactly 67 fields available on the platform, of which 12 are highlighted as the most popular. This analysis takes into consideration only four of them, which currently belong to the popular ones: “Graphic Design,” “Web Design,” “Interaction Design,” and “UI/UX Design.” The fields chosen are representative of this type of research, which aims to explore the different areas of Communication Design. From a more traditional “Graphic Design” to the most recent “UI/UX Design,” “Interaction Design,” and “Web Design,” the aim is to show for each one the number of people that selected it, the country where these people come from, and the number of likes they received. The analysis considers a large sample as the number of profiles scraped—15,000—which required a custom scraper for obtaining the data. Once the data were collected, it was also possible to determine the gender of first names. By using Genderize.io API, based on a database of 216,286 distinct names across 79 countries and 89 languages, it was possible to recognize the gender. The API returned indeed “male” or “female” together with a number representing the frequency of the

\(^3\) behance.net/yearinreview - Behance “year in review,” 2015
Where do Graphic, Web, Interaction, and UI/UX designers come from? How much are they appreciated? In order to find answers to these questions, we designed four bubble world maps, one for each field (see Figure 16). Each country is thus represented by a circle, which is as big as the number of profiles indicating that country. The thickness of the outline of this circle represents instead how much that country is appreciated on average. Another map (Figure 17), for each field, shows through squares the number of people for each country normalized for population number. So it is possible to compare the two maps in terms of absolute and relative numbers.
Figure 16. Behance bubble world map: “A world of Web designers.” Data: 15,000 most appreciated people with “Web Design” as creative field.

Figure 17. Behance bubble world map: “A world of Web designers – Normalization for population.” Data: 15,000 most appreciated people with “Web Design” as creative field.
Discussion

The main research findings confirm that: a) Communication Design is an ill-defined area, an often-confused disciplinary field with a series of new links and overlappings with other areas and disciplines (findings from Wikipedia); b) Communication Design is not used as terminology outside the academic domain (findings from Google); c) platforms like Behance offer a sub-categorization of design that pushes more and more toward a deeper specialization; and d) in the academic domain also, an increasingly large number of specific and diverse degrees has been activated. In the following pages, more specific discussions about each single Web environment will be presented.

Wikipedia

This study has identified a scarcity of Wikipedia language versions for the subject “Communication Design.” The article is indeed available only in ten languages (out of 284 active), of which two, the German and Portuguese ones, redirect to the pages that correspond respectively to “Graphic Design” and “Visual Design.” This confirms what scholars have told us over the years about this specific area: that “Communication Design” as terminology has been introduced in relatively recent years and that it has been interchangeably used as a synonym of many other subjects, such as the ones just mentioned. Furthermore, it was found that, apart from the English and German editions, the other article versions are quite poor in terms of content and not very well-structured; it is also interesting to discover that in an area in which visuals are of primary importance, no images are actually present in the articles.

However, Wikipedia has been identified as an interesting forum for digital research and performing a co-occurrence analysis of common and unique concepts (identified with internal links) has brought to light some curious findings. For instance, all the language editions mention a common list of fields related to Communication Design, such as “Advertising,” “Illustration,” “Web Design,” “Graphic Design,” etc., which reflect the nature of this wide discipline. In opposition to common concepts, unique concepts also emerged, such as the concept of “Humanitarianism” mentioned by the Chinese edition. Another interesting fact is what is not mentioned: for example, the new areas of “UI/UX Design” and “Interaction Design,” as well as many others. It is difficult to say if the similarities and differences found across these different Wikipedias actually reflect the offline situation, but it seems that there are some cultural influences. As for further explorations, it would be interesting to see how the articles will evolve in the future, and if more designers will engage with this task of making the area of Communication Design more understandable within the open Encyclopedia.

Google

By treating Google Web Search as a research tool, it has been possible to assess the importance that universities, organizations, companies, or other entities can have in the context of the use of the phrase “Communication Design.” The results that emerged from this query were significant in revealing that Communication Design is mainly intended as a discipline; in fact, this terminology was mostly used among universities: out of 100 results, 69 were referred to the web pages of universities, which typically showed their degree programs
Furthermore, the study in this chapter found that with link analysis it is possible to determine the impact of an actor (such as a university or an association) in the generic Web. This means that it is possible to figure out which are the actors that sit at the “virtual roundtable” imagined by Rogers (2009) for the Communication Design topic. It was discovered, for instance, that AIGA and Adobe have a considerable online reputation, since they were the most linked of the networks. To summarize, through the analysis of the actors appearing on Google ranking and the links between them, it has been possible to discover who was actually dealing with this topic. Since the Web moves very fast, as a further step, it would be interesting to see how this network will evolve over a period, and also, how it will change by using as queries those synonyms utilized by many, such as “Graphic Design,” “Visual Design,” etc.

Universities

With a view on the Design programs offered by the 100 top design universities of the world, a first mapping of the academic offer around this topic has been traced. Even if it is a partial view, a mapping of the program names belonging to the sphere of Design, represents at least a first sketch of an open dictionary made of terminological differences and similarities. What emerged from this mapping was a big diversification in the program names, in the areas covered, and in the levels of specialization. The maps showed 144 and 179 different names of Bachelor and Master degrees. This analysis also opens up a series of questions regarding the academic perspective on the boundaries between Art, Fine Arts, Design, and Science. Indeed, despite the fact that Design is today considered as a discipline separated from the sphere of Art, the greatest number of Design programs analyzed appeared to be under the titles of Art and Fine Arts, while only a few were considered as degrees of Design and Science (Figure 18).

![Aluvial diagram of the information extracted from the top 100 design universities of the QS Rank](image)
The aim of this mapping was to discover the common and unique patterns of an ever more variegated academic offer, but further steps could be taken. First, the number of universities for analysis could be expanded in order to map all the existing ones in the Design field, and not just those of a certain rank. Also, for instance, what these programs actually offer in practice, what kind of courses, methods and approaches they use and how this changes over time, could be identified, in order to compare them at a deeper level.

Behance

In this chapter, the architecture of Behance, with its search possibilities and digital objects, has been “repurposed” in order to respond to the initial questions. With this analysis it was made clear that this platform offers good opportunities for analysis from a digital research perspective. Thanks to its taxonomic classification of creative fields, its filter system, and its well-structured architecture, Behance offers a great environment for exploring the creative world. By following its structure, it has been possible indeed to observe the designers of today.

In order to focus on the area of Communication Design, we consider only four creative fields. Obviously, the same analysis could be reiterated for all the others available, in order to cover all Design areas. Additionally, since the platform works as a portfolio of visual materials, another type of analysis could be done on this platform. This would be the approach to research that Manovich calls “Cultural analytics” (2008): an analysis of images’ features in order to capture differences and similarities among projects and different countries, to see trends, or to see how all of this changes over a period, for example. In conclusion, it can be said that Behance, to use Weltevrede’s words (2016), is a “good digital device” for research on this field.

Conclusion

To summarize, the research, result of the collection, analysis, and visualization of the data gathered from the Web, led to the creation of a tool, composed of a set of visualizations, which allows the observation of the complexity emergent from the four environments selected and analyzed. What has been found is that thanks to the new research possibilities that the Web offers and thanks to these new, easily accessible computational methods, we can take advantage of such approaches to achieve knowledge and awareness in a particularly fertile territory on the online sphere: Design.

The research here discussed is a first step, a first methodological experiment, which could lead to a systematic observation of the field on the Web sphere. The exploration could be expanded in the future and deepened at several levels. For instance, it might be interesting to systematically show the evolution of these data over time. Moreover, they could be explored, using the same protocols, along with other design areas, such as Product, Fashion, or Interior design. The same sub-fields that emerged from this research, such as UI/UX, Web design, Interaction design, Graphic design, etc. or other online environments could be deepened and explored.

This study doesn't pretend to provide a comprehensive view of the topic on the Web and its
results are not error proof. Rather, it tests a new approach and method of research in the Design research field, through visual experimentation. At the beginning, we talked about a first mapping, a first orientation; in fact, this research is only a small step in this direction. Although it was conducted with the support of different disciplines—from statistics to computational sociology—a design-oriented approach has been essential to conducting the research, from the definition of the questions to the design of a methodology and of a visual tool to communicate the results.

Design, therefore, has played a key role in this research, not only as an object of study: this was, indeed, a research both about design and conducted through design (Fryling, 1993/4; Findeli, 1995). We are fully aware of the limits and the novelty of such a research and of the fact that it represents only a partial view over a huge world that needs many more resources to be explored.

**Paolo Ciuccarelli**
Associate Professor at Politecnico di Milano, he teaches at the Faculty of Design in the Communication Design master degree. He has been visiting lecturer at Universidad de Malaga and The Royal Institute of Art (KKH – Stockholm) and participated to several postgraduate courses in other universities. Since 2000 he represents the Faculty of Design in the European program “MEDes” (Master in European Design). Head of the Communication Design Research group and member of the Design PhD board, both at Politecnico di Milano – Design Department. His research and publishing activities focus on the development of data, information and knowledge visualization tools and methods to support decision making processes in complex systems. He’s founder and scientific coordinator of POLIteca, the Design Knowledge Centre of Politecnico di Milano.
Taking aim at ‘wicked problems.’ A practical philosophy for educating designers in the making of wise decisions

Paul Emmerson, School of Design, Northumbria University, paul.emmerson@northumbria.ac.uk
Robert Young, School of Design, Northumbria University, robert.young@northumbria.ac.uk

Abstract

Today’s design pedagogies lack the characteristics for redressing the nature of the ‘wicked problems’ they attempt to solve, such as sustainability. We argue it is not fair for future generations to suffer the systemic effects of our unsustainable consumer culture, partly resulting from today’s design professionals’ decisions, which ensue because design is an amoral discipline lacking a systemic perspective.

To rectify design’s characteristic failings, as part of a PhD study, we report a new pedagogical architecture founded as the synthesis of the practices of design and civics, forming the relationship design-as-civics (DaC): a practical philosophy. We position DaC as a reflexive, systemic radical political praxis for every citizen, possessing the explicit teleological goal to achieve the ‘good life’ for all.

DaC takes a transdisciplinary approach. It integrates the discoveries of cognitive science and linguistics to expose how we construct our understanding of the world interpreting metaphors and frames, which we utilise to ‘aim’ DaC. Alongside shared social practice theory (SSP) and insights from developmental psychology that reveal the distinctly human capacity of “shared intentionality” engendering humankind’s willingness for cooperation and empathy for fairness. That living in a fairer society is desired by people from rival political perspectives, with egalitarian societies reporting lower environmental impact lifestyles and more willingness for transitioning towards sustainment.

Thus, it is humankind’s cooperative behaviour and aligning values that provides the foundational rationale of DaC’s SSP goal to achieve the ‘good life’ through the ongoing critical examination of its ‘aim’ of resolving ‘fairness between citizens.’

Design as Civics, Sustainability, Civics, Sustainability as Fairness, Fairness between Citizens, Generative Metaphor.

The statement by the 19th century philosopher and a founder of sociology, Compte (1798 - 1857); “The living are now more and more governed by the dead” (White 1921 p.36), holds inescapable truth today as we reflect upon the imposition on future generations of the absence of fairness resulting from the dominant ‘western culture’ of consumerism. The absence causes systemic interconnected environmental, economic and social problems referred to as the issue
of sustainability (European Environmental Agency 2012; IPCC 2014; Stern 2007).

Design professionals’ decisions are absent of fairness because design is amoral (Jonas et al., 2009 p.104/6) and lacks a systemic perspective. Moreover, today’s designers and pedagogies of design predominantly focus on supporting the needs of capitalism’s neoliberalism, metaphorical ‘free-market’ ideology that drives consumerism (Lovins et al., 1999).

**Literature Review**

In contemporary industrialised societies, scholars agree on the phenomena of how citizens and designers passively accept technological innovations and consume without critical engagement (Papanek 1974; Manzini & Cullars 1992 p.5; Margolin 2006; Walker 2008; Fry 2011 p.ix). For example, Margolin exposes industrialised societies’ failure to ask whether the, “onslaught of new devices, systems, and social practices,” improves our lives (Margolin 2006 p.118). Moreover, Manzini and Cullars announced a decade earlier how design continues to lack an ethics of practice (Manzini & Cullars 1992 p.5).

Thus, it seems remiss that with decades of design scholars' thoughtful protestations, design pedagogies and professional designers predominantly remain unfocused on applying critical thinking to what we argue are their social responsibilities: of assisting citizens to question what lives or social realities they desire, and how to get there.

The free-market paradigm dominates citizens’ and design’s agenda, leaving design ill-positioned and possessing the wrong characteristics for tackling ‘wicked problems’ (Rittel & Web 1973). As Margolin declares, we “lack a calculus of values that can enable us to assess the worth of new experiences” (Margolin 2006 p.118). Whereas for the philosopher and educator Freire, his concern was how the day’s dominant paradigm “absorbs those within it and thereby acts to submerge human beings’ consciousness” (Freire 1972. pp.27-28), echoing Shove’s thoughts that our every day to day living – our shared social practices (SSP) such as consuming – become invisible norms of society (Shove 2011 p.88). Moreover, for Diamond, ‘submerging’ is what he terms as “creeping normalcy” leading to society’s ‘unconscious’ gradual local habitat demise (Diamond 2006 p.443).

Together, we recognise Freire’s call for citizens to develop their “critical consciousness” (1972 p.150), Margolin’s call for a “calculus of values” (2006 p.118), alongside Manzini and Cullars’s desire for an ethics of design practice (1992 p.5) as being akin to the constitutive elements of the praxis of civics. Civics being a praxis of citizens to question; “how do we achieve the ‘good life’ for all citizens?” We propose that to achieve the ‘good life’ in our unsustainable era requires as a priority the rationalising and emphasising of the systemic relationship between fairness and sustainability.

Our theory draws on civics as taught by the ancient Greek scholars Isocrates and Aristotle. In doing so, we argue:

That we respond to sustainability literature’s calls for initiating practices of sustainable development that provide new thinking and new ways of living that promote the embracing of efficiency alongside sufficiency (Cooper 2000 p.50; Cooper 2005; Mauch, North and Pulli
That sustainability is not “definable, understandable and consensual,” it is an ongoing ‘wicked problem’ (Rittel and Webber, 1973 p156; Conklin 2005; Levin et al., 2012) requiring the deliberative attention of citizens able to redress the absence of intra-generational and intergenerational fairness (Fry 2009 p.42) from the frequently used term to describe sustainable development.

That sustainable development is; “development which meets the needs of current generations without compromising the ability of future generations to meet their own needs” (World Commission on Employment and Development 1987 p.16).

Research Aim

In this paper, we argue for the explicit embedding of the value of fairness within a reflexive practice of civics and design forming the theory of practice we term design-as-civics (DaC). Whereby DaC is a reflexive, systemic radical political praxis for designers, design students, and our ambition, a shared social practice of citizens: in other words, we position DaC as a practical philosophy. We use the term practical philosophy to differentiate DaC from how philosophy is typically discussed today, devoid of action. We reconnect it explicitly with philosophy as practised by the ancients Greek: that philosophy is the way to live life towards achieving happiness – or the “good life” (Aristotle AD350 NE Book I p.8). Thus, philosophy here, with its theory and practice to achieve the ‘good life’ is a praxis possessing a value-rationality. A praxis for developing the citizen’s phronetic skill of making wise decisions in uncertain conditions (Flyvbjerg 2001 p.55-57). As Aristotle states, it is that we learn by doing (Aristotle AD350 NE Book II p.1) and through such actions, “we become just by doing just acts” (Aristotle AD350 NE Book II p.1).

We also contend that fairness represents the overarching principal principle value; to provide DaC the moral characteristic to ‘aim’ its practice in critically interrogating “wicked problems” (Rittel & Webb 1973) affecting our societies. And by reframing sustainability as a proposition that the world’s cultures can readily interpret – the value of fairness – we remove today’s obscuring technocratic specifications, or “empty phrases” (Voss, Bauknecht and Kemp 2006 p.3) that hinder its understanding and prevents change.

In highlighting the absence of fairness concerning sustainability, to aid our thinking – and DaC practice – we propose discussing sustainability as the systemic relationship frame term ‘sustainability as fairness’ (SaF). It thus entails that we can write the pedagogy framing of DaC as (design as civics) as (sustainability as fairness). Alternatively, to aid transparency and ease of use, the expression DaC as fairness. Subsequently, we can state DaC’s goal is to achieve the ‘good life’ through the ongoing critical examination of its ‘aim’ of resolving ‘fairness between citizens’ (FBC).

Thus, in defining DaC, we agree with Margolin’s contention, that; “design theory at its most fundamental ought to be a theory of how design does and might function in society rather than simply a theory of techniques” (Margolin 2002 p.238), echoing similar thoughts on the nature of the practice of design by Papanek (1974 p.17), Jones (1981 p.9), Alexander et al., (1977),
Cross (2007 p.47), Nelson and Stolterman (2003 p.290) and Fry (2011). DaC also remedies Papanek’s pedagogical concern that schools of design, “teach too much design and not enough about the social, economic, and political environment in which design takes place” (Papanek 1974 p.235).

Structure of Paper

Having outlined our contextual interpretation, and put forth DaC as a path forwards, the following sections develop through a series of short discussions our rationale for DaC foundational elements.

As fairness is a relational value between others – our fellow citizens, local and global – we start our discussion by reporting fairness’s human evolutionary origins. Subsequently, the relationship of values with frames and conceptual metaphors; moral politics (figure 3); values and cooperation; and lastly morality and fairness. We organise our thinking as an overview of DaC in Figure 5. We then briefly report DaC in practice to highlight how the theory starts to resolve as praxis.

However, we first redress the contradiction held within our claim; how pedagogies of design lack the characteristics to redress ‘wicked problems’ due to its amoral nature, as informed by our citing of Jonas et al., (2009), when these scholars contend design’s amoral nature is a virtue needing preserving (Jonas et al., 2009 p.104/6).

Design: an amoral practice

So far our argumentation positions DaC as addressing design’s amoral characteristic (Jonas et al., 2009 p104/6). However, Jonas et al., proclaim how making design moral is a mistake: that it portrays design as an immature discipline (Jonas et al., 2009 p.104/6). Instead, they position design’s amoral nature as a virtue, that it is essential for design to be ethically uncritical (Jonas et al., 104/6). They state that design as a 2nd-order cybernetic discipline, for the designer “to evaluate the representations of reality by comparing them with reality itself” (Jonas et al., p. 104/6) is problematic because the designer’s perspective becomes a tautology of them comprehending observing their observations. For example, ‘I see a cat is black because I see a black cat,’ is remiss of external objective verification. (See Dubberly & Pangaro 2007 for explanatory diagrams of 2nd-Order Cybernetics)

In developing the reflexive relationship of DaC we assert we redress these concerns. We first provide DaC with an explicit teleological goal, knowing that, as White explains, “there is in it a grand unfinish” (White 1921 p.17): to deliver the ‘good life’ for everyone using FBC as the contemplative metric ‘aim’ that generates multiple personal perspectives through the co-performances of DaC practitioners. As such, and important to recognise, DaC possesses a value-rationality, the antithesis to the instrumental rationality of neoliberalism’s ‘free-market’ economy (Brown 2006 p.711).

DaC practitioners triangulate through discourse to reflect on the nature of how FBC resolves within the context of the lives that their decisions affect. These include their own within the systemic relationship of living within their history, geography and occupations comprising
their city, which we later discuss as the concerns of the practice of civics. In Von Foerster’s constructivist paradigm, “reality becomes communality and community,” through the experiences of people sharing discourses (Von Foerster 2004 p.13), such that in creating “communality and community,” the act of sharing – of living socially – represents the triangulation of the realities of those that matter: ‘we collectively agree a cat is black because we all see a black cat.’ That through sharing lives – performing actions and discourse together – practitioners reflexively change the knowledge and practices upon which their initial thinking drew: in other words, through discourse and making interventions practising DaC – in the true Aristotelian sense – they live philosophically (Hadot 2004 p.138). In living philosophically, they transform themselves, their habitus (Hadot 2004 p.176) and collectively create the society they desire. It creates Mode 2 knowledge that is reflexively politically accountable to the community (Gibbons et al., 1994 p.3) advancing, we argue, Rittel and Webber’s call for an “argumentative process” for answering ‘wicked problems’ (Rittel & Webber 1973 p.162).

Thus, we follow Vygotsky’s claim of how human culture – a social process – forms the citizen's mind (Vygotsky 1978; Barret 2011 p.36). That, our functioning is not solely the result of innate natural behaviour, but that mankind, “constructs himself” (Vygotsky 1989 p.65) and his understanding of reality from within their social context (Berger & Luckmann 1971), through their practices (Schatzki 1996 p.13; Reckwitz 2002; Shove, Pantzar and Watson, 2012). Such thinking is also represented in the theories of Lakoff & Johnson concerning metaphor (1999; 2003), and Tomasello (2009a; 2009b and 2014) researching developmental psychology.

And explicitly, that DaC’s principal principle, the conjectures and interventions realised are all shareable as permanent records for ongoing scrutiny by fellow citizens.

The above arrangement of DaC praxis, we argue, annuls Jonas et al.’s concern of design and professional designers colonising the moral space inadequately (Jonas et al., 2009 p.104/7), and ontend DaC is appropriate and justified in being a second-order cybernetic practice (Scott 2004). It recognising how “all knowledge is seen as dependent on the observers’ involvement” (Glanville 2009 p.80), that it’s their collective observing the observed that creates the ‘good life’ (Figure 1) as they “become just by doing just acts” (Aristotle AD350 NE Book II p.1).
How morality and fairness arose in human nature is contested, with theories promoting that of altruism (Fehr and Fischbacher 2003) and mutuality (Tomasello 2009a). We find Tomasello’s (a developmental psychologist of the Max Planck Institute for Evolutionary Anthropology) positioning of mutuality first followed by altruism, insightful (Tomasello 2009a p.85). He states, “homo sapiens are adapted for acting and thinking cooperatively in cultural groups” (Tomasello 2009a p.XV) and distinctly equipped with social skills for regulating their behaviours in social contexts.

In human infants from around the age of one, emerges the social skill of understanding the intentions of others (Tomasello, Carpenter, Call, Behne 2005 p.675). This “shared intentionality” is motivated to form cooperative actions, the helping and sharing with others (Tomasello 2009b p.321) resulting in mutualist relationships forming, and precedes a child’s development of “understanding beliefs” (Tomasello 2005 et al., p.675). The beliefs the child’s culture hold and moulds into its children. These cultural beliefs, alongside the member’s capacity to, “suppress their own interests in favour of those of others or equate their own interests with those of others,” are essential for cooperation (Tomasello & Vaish 2013 p.251).

The shared intentionality of a “joint goal” (Tomasello 2009b p.321) of early human cooperative acts arose in hunting and gathering expeditions, whereby the rewards were fairly distributed (Warneken et al., 2011). Figure 2 depicts Tomasello's documenting how young children in ‘joint tasks’ share the rewards fairly (Macdonald, T. 2013 t.24’).
Here we see the psychological processes of fairness, of human cooperation and morality, evolving hand-in-hand as the means to enhance a group’s collective potential. Knowledge, skills and practices develop – including civics – with their transmission and evolution determined by the community’s culture. We draw upon the above insights as providing the explanatory and practical insights for theorising DaC as a SSP of citizens: where FBC is realised through instigating humankind’s innate nature of fairness in ‘joint goal’ activities.

Figure 2: Prof. M. Tomasello explaining to Prof. A. Roberts his study exposing how children in 'joint tasks’ share the rewards fairly (Macdonald, T. 2013 t.24”).

How metaphors frame our understanding of situations

Cognitive science reveals how our brain’s conceptualisation of the world builds its understanding of reality interpreting metaphors within language (Lakoff & Johnson 2003 p.3). Metaphors reside as physically encoded synaptic ‘frames’ within our brain (Lakoff 2002 p.145) which we recall, often unconsciously, when say voting, to our concern here, of practising DaC (See Lakoff & Johnson 2003 for discussion on conceptual metaphors).

Schön exposes the unconscious implications of generative conceptual metaphors dramatically within the “problem-setting of social policy” for two USA urban housing projects (Schön 1993 pp.262 - 265). One framed the problem as blighted recalling the conceptual metaphor frame of ‘disease,’ and its response, to eradicate. The area was razed.

The other housing problem-setting frame, following discussions with local citizens, focuses unconsciously on the conceptual metaphor ‘natural community.’ Here the officials’ response to the conceptual metaphor drove their intervention to nurture elements representing ‘home,’ with “unslumming” restricted to specific interventions (Schön 1993 p.263).

Metaphors thus unconsciously and consciously inform our reality shaping the nature of our actions (Lakoff & Johnson 2003 p.158). However, their role is complicated by our moral politics.

Values, metaphors and moral politics

Nearly “all moral concepts are defined by metaphors” (Lakoff & Johnson 1999 p.325) motivating an individual’s position on political issues, such as sustainability. Cognitive linguist George Lakoff identifies, and terms as ‘moral politics,’ two distinct conceptual metaphors
framing the USA’s public discourse, dividing conservative and liberal positions. These are the ‘Strict Father’ and ‘Nurturant Parent’ models (Lakoff 2002) (Figure 3).

We oversimplify the richness and thoughtfulness of Lakoff’s thinking and keep our discussion to how his ideas relate to sustainability and ‘wicked problems.’ The conceptual metaphor of the ‘Strict Father’ model, Lakoff equates to the frame of the ‘free market’ ideology of capitalism (Lakoff 2002 p.213) and thus its instrumental rationality (Weber 1978 p.85; Brown 2006 p.711).

Its moral emphasis focuses on the value of ‘freedom’ of the individual. That one’s moral politics is to self-determine one’s actions, with life a competition for personal success – the increasing of one’s financial worth (Lakoff 2002 pp.67-69). Moreover, in this frame, man as a steward has mastery over nature. Exploiting the bounty of nature’s resources is thus argued as being morally good (Lakoff 2002 p.213).

Diametrically, Lakoff’s conceptual metaphor ‘Nurturant Parent’ model equates to how the whole community must benefit from the market’s commercial activities (Lakoff 2002 p.216). The conceptual metaphor of ‘nurturing’ promotes; responsibility for caring for oneself, while explicitly recognising that cooperating fairly, with mutual respect and empathy, as a member of a community, benefits everyone’s wellbeing. Significantly, nature is not under the stewardship or control of man as a resource for exploitation, but considered, metaphorically, as “nurture-as-mother” (Lakoff 2002 p.216).

As such we recognise how one’s personal values intersect with the ‘moral politics’ frame used in the dominant ‘free market’ discourse. How it informs – often tacitly – the individuals response to
societal issues such as sustainability. That such ‘moral politics’ discourse is embedded as path dependencies within everyone’s SSP, and today’s discourse of design, preventing change.

Values and emotions

According to Schwartz, values are what we each hold as important to our lives (Schwartz 2012 p. 3). A person’s core values – their principles – may include security, freedom, friendship, learning and fairness.

Psychology theorists; “view values as the criteria people use to evaluate actions, people, and events” (Schwartz 2006 p.0). Thus, when we talk about the long-term issue of sustainability – the interconnecting elements of; “social equity, environmental justice and business ethics” (Elkington 1997 p.72) – and ask, ‘are disposable plastic water bottles good?’ we can take a personal view as to the absence, or not, of fairness. However, values are not fixed or determinate. Values are beliefs guided by our emotions (Schwartz 2006). So, one’s response to the above depends on one’s moral politics worldview.

Of importance to our discussion here, is how psychological experiments, such as the Ultimatum Game – a joint action game between two unknown participants, establishes how fairness (or equality) is chosen rather than monetary gain (Tomasello 2009b p.187; Gintis, Bowles et al., 2003 p.157; Henrich, J, et al., 2005 p.815). These findings contradict the prevailing ‘economic man’ or ‘utility theory’ espoused by the ‘free-market’ – of how individuals are supposed to determine monetary gain objectively and maximise their self-interests, their “material welfare” (Heylighen et al., 2006 p.5). Bechara and Damasio stating, “Modern economic theory ignores the influence of emotions on decision-making” (Bechara & Damasio 2005 p.336) and of how people feel when confronted with ‘utility theory’ practices going against their internal norms of fairness.

Summary of Fairness

Values such as fairness are experiences of everyone’s every day. It is our nature to continually evaluate the day’s happenings emotionally using our values in context. As fairness is an internalised human behavioural norm (Fehr and Fischbacher 2003 p.785), one way we can consider our ability is to see it akin to being an expert’s professional skill, an intuitive skill (Dreyfus 1997 p.22), which humans develop naturally through day-to-day practice. A skill having universality, meaning that we can engage as plainly with our neighbours as we can with citizens around the world. DaC’s goal is to attune this skill for revealing the ‘good life.’
In using FBC as DaC’s evaluation metric for achieving the ‘good life,’ we are simplifying for ease our positioning of what the ‘good life’ entails. We correspond FBC and the ‘good life’ explicitly towards Schwartz’s study on the nature of human values and what he terms as Self-Transcendences (Figure 4) while possessing Openness for Change (See Schwartz, S. H. 1994 Figure 1 P.24 & Figure 2 p.31).

Whilst we acknowledge the difficulties of values in practice, social scientists Wilkinson and Pickett report that people, regardless of political background, desire a more equitable society. They state that, “in more egalitarian societies, more people are oriented towards inclusiveness and empathy” (Wilkinson & Pickett 2010 p.168), which in turn leads to lower materialism behaviours reducing a society’s CO2 output. The benefits of a fairer society echoes in the work of Roberts and Parks (2007), Dorling (2010) and Kasser (2011) and suggests potential to assist redressing other societal problems (See Wilkinson & Pickett 2010).

The above, we argue, collectively indicates how drawing on the value of fairness provides the praxis of DaC with a principal principle moral basis for engaging in discourse whose ‘aim’ is for FBC to address sustainability.

Building a theory: The SSP of DaC

Civics is a systemic praxis of citizens considered by Aristotle as, “a moral and intellectual virtue,” for delivering the ‘good life’ (Carr 2006 p.426). Civics concerns the development of the engaged citizens’ skills of phronēsis – the practical wisdom to make the right choice in conditions of uncertainty (Poulakos 2004 p.54).
Epicurus, an ancient Greek philosopher (AD 55 - 135), states; “You are a citizen… ‘And part of the world…’ The duty of a citizen is in nothing to consider his own interest distinct from that of others” (White 1921 p.15). Civics is the ongoing political process of advancing the standards of citizens’ lives through engaging and nurturing the “knowledge, skills, values and motivation to make that difference” (Ehrlich 2000 p.xxvi).

Isocrates’s goal was to teach logos politicos – reasoned discourse concerning the city (Rahe 1994 p.21) – such that a citizen’s art of rhetoric in presenting discursive arguments that explore, theorise and invite actions to enhance their city, gain patronage. The citizen’s performance – of understanding their city, its citizens, and the implications of their actions within – was to Isocrates an approach to living: a practical philosophy. It is the; “means of training for life, which transforms human relationships and arms us against adversity” (Hadot 2004 p.50), such as our unsustainability. Isocrates’s teaching is the means for developing the citizen's skill of phronēsis – their practical wisdom – integrating their doxa – belief, opinion, conjecture, judgement – to create prudent conjectures towards realising the society they desire when conditions are uncertain (Poulakos in Poulakos & Depew 2004, p.52-56). Figure 5 - part C describes the multi-layered structure of DaC from interpreting Isocrates’s depiction of civics (Poulakos & Depew 2004).

However, phronēsis, like design, is amoral. As Eikeland explains, “it presupposes knowledge of ethically and political ‘virtue’” (Eikeland in Reason & Bradbury 2001 p.148). It is our contention to ‘aim’ DaC towards the value of FBC through drawing upon the intrinsic motivation of practitioners for self-determining (Ryan & Deci 2000) the interpretation of a generative conceptual metaphor. One possessing a nurturant parent moral politics. But before we describe the metaphor and its use in Section 5.1 we introduce the knowledge base required for civics.
Figure 5: Overview of DaC – A value-rational praxis of citizens whose goal is to achieve the ‘good life.’
White argues that to practice civics requires studying three main elements of the city, the: “geographical, historical and the occupational or economic” (White 1921, p.35). Their meaning meditated and reflected upon through the city’s citizens’ practice of civics (Figure 5 - Section A). Such a strategy we see occurring in how the Tikopians of the southwestern Pacific Ocean maintain their society: by ensuring everyone knows their island resources on which their collective wellbeing rests (Diamond 2006 p.444). The town planner and sociologist Professor Geddes best captures the dynamics within civics, stating how; “A city is more than a place in space, it is a drama in time. ... To realise the geographic and historic factors of our city's life is the first step to comprehension of the present” (Geddes 1904 p.108). Thus, we contend, understanding of the present enables the designer’s ‘aim’ for FBC.

Figure 5 depicts the study of civics (A). To this description of civics, we integrate design to form the reflexive relationship DaC. Its practice being for citizens to apply their skill of phronēsis to ‘aim’ change towards the value of FBC and achieve their goal of the ‘good life’ (B). Figure 5 part C DaC’s inner layers formalise Isocrates’s thoughts graphically on teaching civics, with part D highlighting our use of Boyer’s engaged scholarship (Boyer 1996) approach to recording educational practice. Useful in the context of DaC to assist citizens’ in scrutinising conjectures and interventions as to if, and how well, they deliver the ‘good life.’

Controlling the ‘aim’ of DaC

Values, frames, metaphors and moral politics interactions are complicated. They shape our lives as SSP, and in our design decisions that affect the lives of others.

In forming the reflexive relationship DaC, as a praxis to develop a practitioner’s skill of phronēsis (Poulakos 2004 p.54), we report how phronēsis, like design is amoral. It too has no intrinsic principle value to ‘aim’ its practice. Although its rationale seeks to reveal the ‘good life.’

Thus, in positioning phronēsis centrally within DaC we integrate a conceptual generative metaphor explicitly to ‘aim’ DaC practitioners’ development of phronēsis for making wise decisions in uncertain conditions that resolve DaC’s principal principle value of FBC for achieving the ‘good life.’

Before discussing DaC’s use of metaphor, its useful to quickly observe metaphors in action shaping our conception of design practice. Schön reminds us that metaphors help us “come to see things in new ways” (Schön 1993 p.255) as illustrated in Suchman’s metaphor for design stating how design is “like steering a canoe” (Suchman 1987 p.52). While Glanville’s “design is a conversation” (Glanville 1999 p.80) provides new comprehension. Taking Glanville’s example, ‘conversation’ is the generative metaphor (the source) that maps onto ‘design’ (the target) as represented in Figure 6.
Earlier we expressed DaC as follows: *(design as civics) as (sustainability as fairness)*, and for ease of use, the expression ‘DaC as fairness,’ where fairness is FBC. Our goal of exerting metaphor is for practitioners of DaC to create their concrete representation of the reflexive, systemic radical political praxis of DaC by critically interpreting the source generative conceptual metaphor.

DaC’s source generative conceptual metaphor is ‘mother.’ And although this paper is a theoretical discussion, it’s helpful to reveal DaC briefly in praxis to appreciate the theory, while acknowledging, due to space limitations, we are unable to detail our methodological and epistemological position.

After undertaking photographic research and discussions to understand the city (See Figure 5B), Figure 7 depicts how a group of undergraduate students working together, assisted by the PhD researcher, started generating their interpretation of ‘mother’ in the designing of a public Makerspace – akin to MIT’s Fablab – (Fab Foundation 2017) for City Library Newcastle (CLN) UK.

Providing context for Makerspace’s purpose, Aude Charillon of CLN, states how librarians “*stand for the sharing of knowledge, information and culture and believe in enabling citizens to exercise their rights by providing opportunities for learning and support for realizing ideas*”
Additionally, recognising our, “need for an infrastructure within the municipality that is able to utilize the innovation power and knowledge within civil society” (Stigendal and Östergren’s in Emilson 2014 p.29), our goal was to use the infrastructures (See Le Dantec et al., 2013) supporting Makerspace, within CLN’s value-rationality ecosystem, to demonstrate DaC and its suitability for replicability within the world’s library networks.

Interrogating their DaC prototype conjectures (Figure 8) the students question, ‘does this feel like mother, is the design welcoming, warm?’ It transitions their generative interpretation of ‘mother’ from the realm of abstract words, to real world understanding, whereby they use their bodies (and brains) in praxis generatively and reflexively to ‘feel’ the meaning of words as subjective critical analysis of their experiences of themselves within the space. In other words, as the means to reason and theorise their aesthetic interpretation of the room’s layout in the praxis of DaC, where words are ‘felt’ and are emotional, their design thinking is embodied (Lakoff and Johnson 1999).

![Figure 8: Makerspace prototype made from corrugated cardboard converted to form modular parts. The students walking and situating themselves in the space, sense-making with their bodies to ‘feel’ their ‘feelings’ towards their design.](image)

Embodied thinking, according to Lakoff and Johnson, is how humans draw upon the body’s perceptual and motor systems to sense-make and reason their experiences (Lakoff and Johnson 1999). For example, the students walk the room looking to ‘feel’ how they feel, examining how their bodies flow and interact with their designs – ‘is it welcoming, warm?’ And in empathising with an imaginary novice user’s apprehensiveness on entering the Makerspace for the first time, sensing ‘experienced gazes fail upon theirs,’ these accounts, we posit, represent how the body and brain work synchronously to shape humankind’s conceptualisation of the world as embodied cognition (Lakoff and Johnson 1999 p.19).

![Figure 9: Designers using the source metaphor ‘mother’ to question their DaC conjectures aim for FBC](image)
To clarify, the students are drawing on the embodied cognition premise of how the body’s perceptual understanding of warmth corresponds with the conceptualisation of the conceptual metaphor, “Affection is Warmth” (Lakoff & Johnson 2003 p.255). Its conceptual metaphorical meaning conceptualising from how “our earliest experiences with affection correspond to the physical experience of the warmth of being held closely” (Lakoff & Johnson 2003 p.255). Importantly, recognising embodied cognition helps develop our appreciation of how we understand the nature of FBC.

Discussion

In creating our theory of DaC we introduced how humankind’s capacity of ‘shared intentionality’ formalises as mutuality, whereby the co-evolution of cooperation and morality arose for the undertaking of ‘joint goals’ reveals the normative human nature value of fairness (Tomasello 2009 p.187). Of how when we work together we share the rewards equally.

However, held within languages are metaphors that frame how humans conceptualise the world – many deriving from the body brain relationship termed embodied cognition (Lakoff and Johnson 1999) – and that often they direct one’s thinking and actions unconsciously (Schön 1993 pp.262-265). Lakoff (2002 p.213) reporting how the moral politics of the ‘free market’ ideology of capitalism frames the use of nature’s bounty as morally right. Such framing we argued is against the goal of the ‘good life’ as it promotes individualism, and possesses an instrumental rationality at the expense of FBC: it prevents a sustainable future (See Figure 4 and Schwartz 1994 p.24). We argue how the value-rationality practice of DaC as a practical philosophy (Figure 3) developing the citizens’ critical consciousness, rhetorical skill and phronêsis, controls instrumental rationality.

In our brief description of students engaging in DaC at NCL, we report how their praxis incorporated their bodies through using the generative conceptual metaphor ‘mother’ to critically analyse their design conjectures. We argue this represents – accepting the embodied cognition premise – that the drawing upon ‘mother’ and its generative metaphorical mapping to the target DaC, is helping activate the students’ conjectures. Their collective political agency towards making wise decisions in uncertain conditions that tend towards the normative morality response of fairness (Tomasello 2009 p.187) – as we hoped.

Significantly it suggests, that as a pedagogy, the SSP of DaC as a practical philosophy, offers a reflexive, systemic radical political praxis with strong potential to enable citizens to redress ‘wicked problems’ though their goal setting of achieving the ‘good life’ through their ‘aim’ for FBC. Importantly, that as Wilkinson and Pickett (2010) and others identify, how more equal societies signify the turn towards sustainability, such that in the praxis of DaC “we become just by doing just acts” (Aristotle AD350 NE Book II p.1).

Using practice-led industrial/product design research to explore opportunities to support manufacturing-related enterprise in Overseas Development Assistance (ODA) countries

Mark Evans, Loughborough University, Loughborough, United Kingdom, M.A.Evans@lboro.ac.uk
Timothy Whitehead, Aston University, Birmingham, United Kingdom, T.Whitehead@aston.ac.uk

Abstract

The profession of industrial/product design has the capacity to support wealth generation through a product-driven supply chain that extends across services that include manufacturing, distribution, sales and maintenance. Moving away from the more typical manufacturing approaches of developed countries, where the resources available to support designers employ advanced technologies and materials, this paper discusses an on-going UK Arts and Humanities Research Council-funded project to explore ways in which industrial/product design can provide opportunities for entrepreneurship and employment in countries on the Organisation for Economic Co-operation and Development (OECD) Development Assistance Committee (DAC) List and receive Overseas Development Assistance (ODA). Through practice-led research with participants from Uganda, Kenya, Indonesia and Turkey; industrial/product design educators/researchers/practitioners shared knowledge and expertise and engaged in creative activity to translate propositions into proposals with the potential for manufacture in each of the four countries. The findings, articulated product visualisations, indicate significant potential to support manufacturing in countries in a variety of levels of economic development by adding value to the packaging of traditional foods; integrating low-cost imported components to add value to indigenous crafts and materials; producing contemporary furniture designs using materials that can be considered as traditional materials; and employing unorthodox and unexpected materials.

Keywords: industrial design, product design, developing countries, practice-led, design practice

Product design-based approaches have the potential to facilitate physical change to quality of life and deliver tangible results (iDE, 2010; UNICEF Innovation, 2016; UNHRC Innovation, 2016; Proximity Design, 2013). Creative product/industrial design has the capacity to identify user-centred problems and commercial opportunities, addressing them through a process that adds value by transforming physical materials into useful artefacts (IDSA, 2015). The range of possible transformations are broad, ranging from the craft-based manipulation of a natural material, such as the bamboo bicycle project initiated by the United Nations (2014), to metal-working and more industrial processes such as wood machining and injection moulding as evidenced in Myanmar (Whitehead, 2015). Regardless of material and process, the intellectual processes of developing a level of understanding of the problem/issue/opportunity, engaging
with stakeholders (users/producers) and devising solutions using the most effective modelling processes (e.g. sketching, mock-ups, prototypes (Evans, 2014) has generic application in developed countries. Whatever and wherever the context, the opportunity for the designed outcomes to enter a scaled-up production process that is aligned with a supply chain network has the capacity to provide employment through material supply, material processing, assembly and distribution (Proximity Design, 2014). While some design-based enterprises may provide employment for a sole trader under a designer-maker model, the opportunities for scaling-up to provide employment for specific and specialist activities opens up the potential to make a significant impact on wealth generation (Polak, 2008).

Governments and Non-Government organisation (NGOs) continue to donate resources to developing countries, but evidence suggests that often these solutions are inadequate to meet the unique needs of local communities (Whitehead, 2015). The current approach typically involves designing and manufacturing products in developed countries which are then distributed locally. This can be described as a top down approach to development which, in some cases, can hinder economic progress in the recipient country and weaken local design activity (Donaldson, 2008). However, a bottom-up approach focuses on creating the capacity to facilitate self-sufficient ‘home-grown’ innovation to address local/regional need and potential for export, with the key outcome being opportunities for employment which can ultimately impact on the alleviation of poverty.

This paper reports on the intermediate findings from a research project to explore how industrial design can support manufacturing-related enterprise in Overseas Development Assistance (ODA) that are on the Organisation for Economic Co-operation and Development Assistance Committee (DAC) List for 2016. This involved the sharing of existing context specific case studies from Uganda, Kenya, Indonesia and Turkey with the generation of project-based case studies that adopted a co-design approach (Sanders, 2002) to identify strengths, weaknesses, opportunities and threats (van Boeijen et al, 2013).

Co-design and the application of User Centred Design (UCD) have been advocated by design consultancies such as IDEO (2011) and adopted as an approach to problem solving by the United Nations High Commissioner for Refugees (UNHRC, 2016). Initial evidence from existing case studies suggest that embedding a UCD design process into the design of products for marginalised people will enhance existing offerings (Hussain et al., 2012).

The aim of the research project, which goes beyond the intermediate findings reported in this paper, is to use resources created through the project to build on existing provision and provide guidance for future creative industrial/product design activity that will facilitate enterprise through the development of a creative economy and ensuing employment/wealth generation.

**Methodology**

The paper reports on research undertaken to address the following objectives relating to the four levels of ODA recipient country which were to:

- Facilitate designer familiarisation with the distinctive cultural contexts
• Identify opportunities for the manufacture of products
• Undertake the industrial/product design of one product opportunity per country
• Establish parameters with which to guide future product development

In parallel with focus group activity, the research employed case studies (Yin, 2013) action research (Birley and Moreland, 1998) to develop understanding in the challenges and opportunities associated with industrial/product design-driven manufacturing in DAC List countries. The four levels of DAC List country were Uganda (Least Developed Country); Kenya (Other Low Income Country); Indonesia (Lower Middle Income Countries and Territories); Turkey (Upper Middle Income Countries and Territories). To ensure breadth of expertise and contextual challenge, academics from leading design schools/departments in each of the four countries were recruited as participants in the data collection.

Countries on the DAC List have been identified as requiring external support for “the promotion of economic development and welfare” (OECD, 2017). Product design contributes to a creative economy. Making/manufacturing industry adds value through the transformation of materials which takes place on a range of scales - from the individual designer-maker to multi-employee high volume manufacturing. In addition to general opportunities for wealth generation through making/manufacturing, specific issues relevant to the development challenges of the four participant countries, and others on the DAC List with similar profiles, have been identified as a lack of support for the development of creative industries in Turkey (Okandan, 2014); an over-dependence on unchanged traditional cultural industries that are tied to tourism in Indonesia (Hampton and Clifton, 2017); and an attitude of “replication over innovation” in Kenya and Uganda (Ekekwe, 2012). By developing, collating and disseminating approaches to creative industrial/product design that resolve these issues and are targeted to the distinctive needs of DAC List countries, entrepreneurial activity can contribute to the generate employment in creative industries and the associated supply chain. The contribution of global academics to this process has been identified by the British Council: “Wherever there is a strong and sustainable hub of creative economic activity, there is likely to be a university that has helped to plant the seed and that continues to nurture local creative businesses and the specialised local labour markets on which they may depend” (Newbigin, 2010).

Method

A five-day collaborative workshop was held at Loughborough Design School in the UK supported by senior design academics from design departments/schools in Uganda, Kenya, Indonesia and Turkey. The activities of Day 1 were also supported by a presentation and feedback by a senior representative from a major UK-based charity that supports technological development in low income economies. Four capable final year undergraduate industrial design students provided additional design support, all of whom had completed one year internships in leading manufacturing and consulting organisations in the UK, Denmark and Holland.

The event and activities were facilitated by the co-authors who were the Principal and Co-investigators for the project that was funded by the UK Arts and Humanities Research Council. As part of the preparatory work for the workshop, the four international participants prepared a presentation to summarise the distinctive context of their country plus two case studies, each of
which demonstrated successful examples in the commercialisation of industrial/product design. They also prepared a design brief for presentation to the participants that would be addressed during the workshop.

The activities were conducted as follows:

- Day 1 Contextualisation – Focus group overview of product development in Uganda, Kenya, Indonesia, Turkey with two product design case studies per country
- Day 2 Practice-led projects – Kenya & Turkey
- Day 3 Practice-led projects – Indonesia & Uganda
- Day 4 Practice-led design development – All projects
- Day 5 Focus group – comparative evaluation of process/outcomes and SWOT analysis

The Co-investigator undertook the role of note-taker for the discussions, with these being used for later analysis. The Principal Investigator facilitated the contextualisation and SWOT analysis in a focus group format using a data projector to display the case studies/design outcomes and white board to collate consensus findings. For all country-based sub-briefs, sketch-driven brainstorming was employed to generate concepts using typical sketching resources that included fine-line pens, markers and a variety of types of paper for sketching.

Whilst the ‘Post-it’ represents a somewhat small format for sketching, its capacity to be used in relatively large numbers over a wall to present and capture design intent was exploited as all participants were industrial/product designers and had the ability to sketch 3D form. Whilst some participants commenced sketch activity on the more typical A3 and A2 marker pads, these were then transferred to Post-its for design review in which those with greatest potential for further development were identified and discussed in greater detail.

**Findings**

During the contextualisation and case study focus group, there was consensus that a significant opportunity existed to export goods to more developed economies where cultural heritage artefacts were valued and premium prices could be achieved. A need and opportunity to move away from an overly traditional aesthetic to one in which cultural heritage was blended with a contemporary stylistic approach was identified, with this becoming the aim of the practice-led design activity. To identify the capacity of this approach to support economic development and provide employment opportunities in ODA recipient countries, practice-led research was undertaken using a design brief to “identify export opportunities that utilise craft heritage and/or indigenous resources as an integral part of a contemporary industrial design aesthetic”.

This brief was addressed for each country using the industrial design expertise of all participants plus the specialist knowledge of the academic from the country for which the design activity was being undertaken. The student designers also supported this activity. A display of the Post-it-based concept generation for all countries can be seen in Figure 1.
Kenya

The strong craft tradition in Kenya was recognised and wide range of indigenous materials as resources for the industrial/product design proposals identified. A significant leather industry included materials that were not typically seen in developed countries, such as Nile perch, ostrich, camel and goat. Craft capability in the weaving of dried water hyacinth had the potential for 3D structures with Masai textiles having a distinctive cultural association a strong/contemporary aesthetic were regarded as a significant opportunity.

Based on the findings from the contextualisation and case studies, the sub-brief identified for Kenya was summarised as “Cultural heritage translated into desirable products for export”. As a result of brainstorming, the following operational bullet points were identified:

- Craft-based production processes
- Contemporary aesthetic
- Potential for raffia, water hyacinth, dried sea grass, baobab wood, jacaranda, fish leather, ostrich leather, Masai textiles, crocodile leather
- Distinctive branding device

As a way of maximising the availability of distinctive leathers and associated craft capabilities, including Masai textiles, the sub-brief selected for Kenya was to explore product design opportunities that integrated these materials in to watch straps. This approach would buy-in contemporary watch bodies for which the faces included a branding device that had an association with Kenya. It was felt that this was an effective way in which to maximise the added value of the leather and textile elements. A developed proposal for the Kenyan sub-brief can be seen in Figure 2.
Turkey

As a country in the Upper Middle Income Countries and Territories category of the DAC List, Turkey has the capacity to design and manufacture products that are comparable with major international brands. This status was clearly made in the two case studies, both of which were for consumer products. Industrial/product design education was recognised as having a broadly modernist tradition due to influences from the USA and Germany. In striving for modernity, it was felt that craft traditions were in decline but the distinctive nature of the nation’s food and drink remained.

Based on findings from the contextualisation and case studies, the sub-brief identified for Turkey was summarised as “Protect, present and serve baklava”. As a result of brainstorming, the following operational bullet points were identified:

- Eat baklava appropriately/effectively
- Packaging system to facilitate group or individual eating experience
- Provide support to prevent breakage
- Baklava to remain crispy
- Distinctive branding device
- Minimal hand contact with baklava
- Maintain structural integrity

Distinctive cultural traditions about the way in which baklava should be served and eaten came out of the contextualisation and provided useful opportunities for innovation. These included rotating the baklava slice by 90 degrees to make it easier to bite into and rotating by 180 degrees to reduce the risk of syrup dripping out. One of the three developed proposal for the Turkey sub-brief can be seen in Figure 3.
Indonesia

Indonesia has a strong craft tradition in the use of bamboo and other natural materials and an opportunity was identified to utilise these materials in the design of furniture. Based on findings from the contextualisation and case studies, the sub-brief identified for Indonesia was summarised as “Use indigenous plant materials in the design of furniture-based products”. As a result of brainstorming, the following operational bullet points were identified:

- Contemporary aesthetic
- Bamboo as primary material
- Rattan, water hyacinth, banana leaf, pandanus leaf as secondary materials
- Elevate status of material

Concept generation resulted in a range of proposals that included fold-out seating, a hammock chair and fold-out chair with rattan seat. One of the three developed proposal for the Turkey sub-brief can be seen in Figure 4.
Uganda

As a Least Developed Country from the DAC List, Uganda started to develop capability in craft and design from the 1960s. However, materials suitable for the manufacture of designed products were limited, with access to basic metal fabrication and a variety of natural resources that can be used for industrial/product design such as gourd strengthened with egg shells, bark cloth and Jacaranda wood (a softwood with the visual quality of a hardwood). As with the Kenya design brief, the potential to integrate available material resources with imported components was identified as a means by which value could be added and a low voltage/heat LED light source identified as a product opportunity. Based on the findings from the contextualisation and case studies, the sub-brief identified for Uganda was summarised as “Lighting design options from indigenous craft resources and metal fabrication”. As a result of brainstorming, the following operational bullet points were identified:

- Capability in local metal fabrication
- Use of bark cloth, gourd, Jacaranda, fabric or leather
- Imported LED light/fitting
- Contemporary aesthetic
- Potential for floor, ceiling, table light

Concept generation resulted in a range of proposals that included a ceiling lamp with matching floor lamp; a modular uplighter/down-lighter/task lamp system; and opportunities to use a gourd as a unique lampshade through a range of lighting options. One of the three developed proposal for the Uganda sub-brief can be seen in Figure 5.

Figure 5. Example of lighting options using a gourd for the Uganda sub-brief
SWOT analysis

Having undertaken a phase of development to translate propositions into more viable proposals, the full range of visualisations were presented and discussed in the focus group. The session was facilitated by the Principal Investigator, with design proposals for each country being introduced in turn followed by more holistic discussions that included comparative interpretation and summative remarks. When translated onto a SWOT matrix in real time during the focus group, to facilitate manufacturing opportunities in ODA countries with potential for export the key strength to be identified as the availability of local and sometimes unique/esoteric manufacturing processes that included the adaption of craft techniques. Key weaknesses were identified as difficulties in internal travel (remote areas); limited ‘conventional’ manufacturing capability; need to audit suppliers for quality control; and the lack of distinctive indigenous materials/crafts in some regions. Key opportunities were the potential to use new and unfamiliar materials; a strong and growing craft tradition in some regions; the potential to expose new and unfamiliar materials to designers; the use of craft materials and processes for packaging; reinforcing the links to the maker for products with a high craft component; and promotion of the value of design by government initiatives. The key threats were import duties on machinery and components; the uncertainty of being able to maintain manufacturing quality; communications in remote locations (telephone/internet); difficulties in communicating immersive understanding of culturally embedded activities (e.g. cooking with banana leaf); significant cultural differences within a single country (e.g. Indonesia with over 250 ethnic groups); political uncertainty; and a decline in some craft practices.

Discussion

Industrial/product designers have a distinctive creative capability to translate product propositions into desirable manufactured artefacts. The research demonstrated how exposure to cross-cultural collaboration could provide novel and unexpected opportunities for product propositions. When employed at a relatively high level, industrial/product design can create compelling and desirable product opportunities from a diverse range of materials and contexts that, in the context of this research project, can be summarised as:

- Adding value to the sale of a traditional food (Turkish baklava)
- Integration of low-cost imported components to add value to indigenous crafts and materials (Kenyan watches, Ugandan lighting)
- Producing contemporary furniture designs using materials that can be considered as traditional material (Indonesian bamboo/rattan)
- Employing unorthodox and unexpected materials (gourd, bark cloth, Nile Perch leather)

A wide range of research methods are available to academic researchers in the social sciences and humanities but, when exploring issues relating to the creative arts, a practice-led approach has the capacity to translate what might appear as abstract concepts into tangible outcomes that can then be used as a basis for research findings. The contribution of this approach to support entrepreneurship and wealth generation in ODA countries is not a trivial undertaking and, if executed as a complete product development cycle, from proposition to product launch, has the potential to provide employment opportunities and improve quality of life for some of the
poorest members of society. This project has demonstrated the first iteration in this process and further work is currently underway to further develop the design proposals and progress these towards manufacture.

Author Biography
Mark Evans

Dr Mark Evans is a Reader in Industrial Design with research interests in design practice that support the development of tools/resources and explore its use during data collection. He has a background as a practitioner for clients that include British Airways, Unilever and Honda. A diverse range of funding sources has generated over 100 academic publications with appointments that include membership of the AHRC Peer Review College; visiting professor at Rhode Island School of Design; editorial board member for two academic journals; and International Scholar at MIT. Recent outputs include the Design Practice Research Case Studies
website for PhDs in which the researcher employed practice to support data collection (9500 views/downloads); the iD Cards design communication tool in collaboration with the IDSA (5000 fold-out cards distributed to members/13000 app downloads); a three month exhibition at the National Centre for Craft and Design for an EPSRC project to explore the commercial opportunities for 3D concrete printing (10159 visitors, 98000 video views); and a design tool/video/website from an AHRC project in which industrial design was used to identify export product opportunities manufactured using indigenous materials/crafts in emerging economies. In 2016 he was the first international member to receive the IDSA Educator of the Year Award.

Timothy Whitehead

Dr Timothy Whitehead is a Lecturer in Product Design in the School of Engineering and Applied Science at Aston University. Timothy is a member of the Sustainable Environment Research Group and has an interest in developing tools and methods for New Product Development in Low Income Economies. Timothy has a bachelors qualification in Industrial Design and prior to joining the university was employed as an industrial designer in a leading engineering consultancy and worked for the Centre for Vision in the Developing World. Timothy is particularly interested in ways design can increase value and uptake of essential products, such as; solar lighting, cook stoves and water filtration. To date he has worked on various design/engineering projects which aim to develop new design tools and methods of practice for enhanced product development. Timothy is also interested in exploring the potential impact of a digital design process and ways in which additive manufacture can be utilised in these markets as a way to bridge the technological divide (www.bridgingthedivide.org).
Impact of Visual Topological Features on Priority Attention for Product Shapes

FEI Fei, Japan Advanced institute of Science and Technology, Nomi, Japan, ffjaiistbs@gmail.com. Dalian Polytechnic University, Dalian, China, ffqhbs@163.com

Yukari Nagai, Japan Advanced institute of Science and Technology, Nomi, Japan, ynagai@jaist.ac.jp

Abstract

This study hypothesized that humans give priority perception to product shapes that possess topological structures. Three experiments confirmed the proposition accordingly. The first experiment selected existing products that grab people’s attention within the prescribed time, with the experimental objects selected according to degree of topological properties and structure complexity. The results showed that visual topological properties in the products had strong visual appeal. The second experiment determined the visual prominence of freely designed and redesigned chairs according to the rating of non-expert users. The results demonstrated that products whose shape adopted topological structures were given priority attention. The third experiment intended to prove the practical value of visual topological features from a direction opposite to that of the second experiment; that is, from topological structures to deconstruction of topological structures. All three experiments showed as well that there are many cognitive limitations in the recognition of topological structures in product shapes. These unexpected problems, such as the contradiction between topological structure and habitual cognition, are discussed. The results of the study and the effects of topological properties on development are also discussed.

Keywords: product shape, visual perception, priority attention, topological structure, topological perception, design

In general, consumers have no access to the designers of the products they buy. Their interpretation of design is based predominantly on their interaction with the product (Norman, D A, 2013). Under normal circumstances, the relationship between a person and a product begins with the visual appearance of the product. Customers tend to identify the features of a product through its visual form, including aesthetic impression, semantic interpretation, and symbolic association (Nathan Crilly et al., 2004). People also match their expectations and level of novelty with a product’s usability (Jan P.L. Schoormans, 2012). By manipulating the appearance of products, a designer can elicit certain emotions from or introduce beliefs to users (Lars-Erik Janlert, 1997). In this sense, a product’s visual form plays an important role.

Literature Review

The composition of the product form consists of colors, materials, shapes and proportions
Shape is probably the first factor and the most significant property of a product that one can perceive from objects (Stephen E. Palmer 1999). After all, industrial designers generally start with sketches of shape, and not the identification of color, in developing new products.

As products in the same product category should be explicitly distinct from competing products, a product’s shape is often the first consideration in distinguishing it from other products in the market (Underhill, P, 2000). The original intention that selecting object comes from the personal preference for shape, just like an influence on people’s attitude toward the objects with sharp angled or curved, and more preference of curved visual objects (Moshe Bar 2006). Meanwhile, people use new form to draw on existing products and develop a new schema (Violina P. Rindova 2007). In the development of a new product, the emotional value of the product is likewise an important factor. A biomimetic shape in product design has been found to meet the emotional needs of people (Tyan-Yu Wu et al., 2015).

Although product shape perceived by the senses has been studied for decades, the focus has been on the aesthetic, semantic, and symbolic aspects of shape. This work focuses on priority attention on product shape, on the premise that customers make unconscious comparisons between competing products based on their visual forms either at the store, physically, or according to their memory of a product image. Another case is the comparison of the reality of the product and the imagined model of the same product. This comparison involves empirical perception. If the actual product is similar or more attractive than the imagined model, the consumer will recognize the designer’s vision quickly. Thus, how can a product gain instant attention?

Research has shed light on the priority of shape recognition. Experimental phenomena are not necessarily consistent with perceptual experience but with topology (Chen, L, 1982). Topological perception based on physical connectivity occurs prior to the perception of other geometrical properties. Topological properties have three manifolds in 2D: connectivity, number of holes, and inside–outside relationship (Chen, L, 2005).

This study aims to investigate the correlation between product morphology and visual topological features, and improve the visual attention on the product form from the aspect of visual topological features. This research adopts the product morphology theory, which provides a new theoretical basis for product form design.

Many experiments have proved the priority of topological perception. These results support the early cognition of 2D graphics, but not in 3D objects. Two-dimensional graphics can contain information on shape implicitly and locally, and in product design, the main shape features of the product can be shown with six visual images. Meanwhile, experiments have been conducted on the perception of shape constancy of 3D objects. Rock and DiVita provided evidence that the shape constancy of irregular objects is poor (cited in Stephen E. palmer
Nevertheless, people can easily recognize familiar objects in multiple perspectives. Based on the above analysis, this study hypothesizes that topological perception exists in product shape and plays an important role in the human cognition of familiar products. In other words, people pay visual attention to product shapes with obvious topological characteristics.

The shape of a product should thus contain topological structure characteristics, so that the consumers can see them immediately. After all, product appearance determines consumers’ first impression (Marie”lle E. H. Creusen et al., 2005). Once their attention is on a product, they can then proceed to understanding other aspects of the product. For designers, visual topological features have a practical guiding significance for the innovative design of product form.

To test the hypothesis, this study designed three experiments. The first one is on the search for visual topological properties in existing products. The second seeks to prove the existence of visual topological features in the form of products through a design project. Lastly, The third experiment intended to prove the practical value of visual topological features from a direction opposite to that of the second experiment; that is, from topological structures to deconstruction of topological structures. Subsequently, this work discusses the positive role and limitations of visual topological features in product form. This research discusses the guiding role of visual topological characteristics in product shape design.

**Research methods**

To confirm the existence of topological structures in product shapes and to seize the attention of consumers, three experimental processes were performed composed of different phases of analysis and validation methods.

**Purpose of the experiment**

Experiment 1 aimed to identify the level of the test using bicycles as test objects. In accordance with the typical characteristics of the topology of the hole, the two wheels of the bicycle tend to be seen primarily as rings. Their shape carries the typical topological property of “hole”. Many concept bicycles have been created, some with a novel transmission structure; a new style of wheels could appear as standard rings. In contrast, the traditional wheel with spokes can be seen as circles. From the perspective of visual topology, circles and rings are topologically different. People are expected to pay more visual attention to the bicycle with the ring wheel. In Experiment 2, typical topological visual features are integrated into the shape design of a chair. The design practice is used to prove the existence and function of topological visual features in product form. Meanwhile, Experiment 3 is based on the disassembly of the inherent topology of a product to prove that morphological innovation at the topology level has a high visual priority.
Experiment procedure

Experiment 1. To test the visual prior attention given to bicycles, three bikes were compared. Images of three bikes were laid out side by side in one A3 paper to enable easy comparison (Figure 1). The pictures of the three bicycles were designed using drawing software. The basic structure and style of the three bikes were consistent to reduce the effect of other factors on visual attention. Considering the influence of watching habits, two test objects in each image were arranged in a different order. To avoid the influence of color, all pictures were presented in gray scale on white background. Sixty-three people from various backgrounds participated in the experiment. They were chosen among college students and their relatives, their ages ranged from 9 to 65 years, with an average age of 24 years. Before viewing the pictures, each participant was told to score each object in accordance with the order of visual attention, with the maximum score of 5 points corresponding to “highest visual attention.” In other words, the object they first noticed should be given the highest score. Based on the results of a preliminary experiment, the experiment duration was limited to 10–15 seconds.

![Figure 1: Example of the evaluation tool used in Experiment 1](image)

Experiment 2. First, eight design students were asked to design one chair freely (Figure 2). Second, each participant was asked to improve a previous design according to specified requirements and elements (Figure 3). To ensure the objectivity of the experimental results, the design scheme was based on the pencil line and white background and should show a 45-degree angle of the chair. Lastly, the two groups of design were combined in a picture, and 20 design non-expert users, their ages ranged from 18 to 45 years, with an average age of 32 years, were asked to score each sketch based on a five-point scale (Figure 4). The experiment emphasized that the subjects focused on the degree of visual attention to the shape of the chair; the function of the chair, manufacturing processes, and other factors were not considered.
Experiment 3. The cup was taken as experimental object. The most common cup shape was used as prototype for shape innovation design. From a topological point of view, the cup and the doughnut have the same structure. To reduce the interference of excessive shape as factor, three new forms were made on the cup handle only (Figure 5). The first two options changed the shape of the cup handle, whereas the third scheme changed not only the shape of the handle but also the topology of the cup. These cups were presented in gray scale on white.
background to avoid the influence of color on attention. At total of 70 people from different backgrounds, ranging in age from 12 to 70 years (average age of 25 years), participated in the experiment. Before viewing the pictures, each participant was told to score each object in accordance with the novelty of the product form, with the most novel being scored 5 points. Based on a preliminary experiment, the experiment duration was limited to 10 seconds.

![Figure 5: Three new forms were made on the cup handle](image)

**Discussion**

In Experiment 1, 63 participants scored three bicycles using a five-point scale. The parameters of the experimental objects are provided in Table 1. Bicycle C was rated to have the highest degree of visual attention, followed by bicycle A. A multiple comparison test for parametric data showed significant differences between bicycles A and B (p<0.01) in terms of average reaction time when rating; similarly, differences were observed between bicycles B and C (p<0.01). The findings further indicated that bicycles A and C received obvious visual attention compared with bicycle B.

In Experiment 2, 20 participants scored 16 chairs using a five-point scale. The parameters of the experimental objects for Experiment 2 are given in Table 2. After calculating the scores in steps 1 and 2, we compared the objects by conducting a paired t-test. The results showed significant differences in average reaction time between the two groups of chairs (p<0.01). The improved scheme of adopting visual topological features in the design shape gained obvious visual attention. In particular, C and E were scored the highest. The shape of C and E had more obvious visual topological features: holes and connectivity.

In Experiment 3, 70 participants rated three cups using a five-point scale. The parameters of the experimental objects for this experiment are listed in Table 3. Cup C was deemed to have the highest degree of shape innovation, based on it gaining the highest score. Cup B ranked second. A multiple comparison test for parametric data revealed significant differences in the average reaction time between cups A and C (p<0.05) and between cups B and C (p<0.05). Cup C had obvious shape innovation compared with cups A and B. From the perspective of product innovation as a measure of the characteristics of visual topology, the shape of the cup itself is a typical visual topological feature, and thus, such a shape has become a common form in human cognition. The novel square and triangular cup handles retain the topology but change the shape, with reference to Euclidean geometry. Nevertheless, when change was made to the form of the glass structure, and although the new shape does not have visual topological features, the redesigned cup still grasps significant visual attention precisely because of the change in topology. This experiment proved that the topological structures have practical significance to product shape innovation.

Discussions

The results of three experiments confirm our hypothesis that visual topological properties exist in the shapes of products. In addition, people give visual attention to a product shape with obvious topological characteristics. After the product gains priority visual attention, the opportunity for
people to understand the attributes of its aspects will greatly increase. Morphological specialization thus attracts the attention of customers, thereby indicating its value in the product development process, compared with costly functional and technical innovation. Especially for newly established small companies, product shape design is a suitable way of development: products with eye-catching shape can grab the attention of consumers, stimulating sales. Indeed, for many famous brands of products in a mature market, which is teeming with similar products, designers focus on product form to capture the attention of consumers (Nathan Crilly et al., 2009). This is an important premise for product brand image promotion and sales. With the perception of visual topological properties as a primitive and general function of the visual system, product shape innovation based on topological structure offers a certain security.

Product shape design is not only for the sake of aesthetics, as the shape of products bears other aspects of information. For example, the use of the product is often encoded in the shape, but these codes can only be identified by product design professionals. Common consumers generally do not notice the coding of these shapes, and thus, they cannot decode accordingly. Visual topological features can be applied to the shape of the coding and seize people’s visual attention, thereby improving the user’s ability to decode product function. Many products work with software, so there are many people who operate new products and do not know how to operate. And because of the simplicity of the product styling, many of the operating keys have disappeared, completely converted into touch plane. In this way, many users who do not have relevant product knowledge accumulation, what is placed in front of them is the product without any clues and hints. In addition to visual topological features has the characteristics of visual priority attention and it also has the possibility of blending with form design at the same time. We can strengthen the visual priority attention of the key operation part by using visual topological features.

This study focused on the attention of people to the shape of products. The perception stage does not belong to subjective consciousness, as it relates to the absence of produced emotion. Distinguishing from simple physical elements in a stimulus can mediate high-level judgments of preference, such as on the sharp angles or curves of an object (Moshe Bar, Maital Neta, 2006); studies have proven the overall preference for objects with rounded rather than angular form, which should be considered in the design of consumer products (Steve J. Westerman et al., 2012). Moreover, the study does not involve the methods of product shape design. According to the key words that describe a product, designers create the shape parameter axis, in accordance with the design guidelines for shape design (Roberta Gorno and Sara Colombo, 2012).

Experiment 2 had discrepancies and revealed unexpected findings. The study created a lot of topology in the product shape. However, a considerable part of the non-topological shape is also a crucial feature of attention. This insight suggests that within the scope of the product
shape, the topology should not be rigidly applied; instead, the semantic, functional, and symbolic conditions of the product itself should be taken into account. Future research should pursue defining non-topological structures in the product form of the product and determining whether it can be considered as a topological structure.

Meanwhile, in Experiment 1, the pictures were adjusted to a degree of similarity in color and brightness, and the main structure of the three bicycles was made similar, to weaken the influence of these factors on visual attention. However, the actual comparison between products is a highly complex process. Apart from the non-topological characteristics of the structure, the material, color, and other elements play critical roles in human visual attention, thereby affecting consumer choice. In addition, knowledge of the product affects priority attention. The experiment clarified that some people know relatively more about bicycles, so the bicycle without hubs quickly caught their attention, and they gave much higher scores to it compared with the other two. Meanwhile, some of the participants selected the bicycle without hubs from a solely visual level, and the gap between scores given is not significantly large.

In Experiment 2, the results verify the superiority of topology in securing priority attention. The design students used topological characteristics in the creation of product concept sketches with a deliberately stressed topology. The other attributes to product form rarely consider, such as aesthetic, semantics, and symbolism in the form of performance, so the second stage of the chair looks stiff and rigid. This issue merits future research.

In experiment 3, some participants recalled the selection process, and they were similar to B and C in visual recognition, but tended to C at the moment of scoring. They also pay special attention to the triangular corners of the handle of the cup B. For this reason, we tried to remove the participants in this situation, and then we conducted second experiments with the remaining 52 participants, and found that there was no significant difference between B and C (p>0.05).

However, there are still significant differences between B and A (p<0.05), C and A (p<0.01). The curvature of handles of B and C are different. The triangular handle of B has higher curvature than the arc handle of C. Because of the principal normal to point into the figure, it point into the handle corner. A concave cusp is a point of negative curvature with the greatest absolute value of curvature. According to the partition rule, a plane curve is divided into parts at negative minima of curvature (Hoffman, D. D., & Richards, W. A. 1984). This explains that the priority attentions are so close of B and C. This gives us some insights into the activities of visual priority attention. There are other morphological structures that can also cause visual priority attention, and then we will study these kinds of features and compare them with visual topological ones.

The experiments anchored sample product selection and comparison on 2D features in the case of the bike and the cup, whereas the chair design was limited to the draft level. Future experiments will adopt 3D presentation, and consequently, research on visual topological
features of structure in product form can yield comprehensive and in-depth findings. Further, the present research involved products with relatively simple structures, whereas future research may focus on complex structure products. We found that the topological invariants and variants of product form relate to the logical relation among the parts of functions of product in this study.

The variants of topological structure occur in each part of the product and its corresponding functions, not only the form of the product changes with the topological variant, but also generates new product cognition and experience to people. If this can be translated into visual node planes, showing a topological invariant or variant model of product design thinking. This model of thinking can inspire the designer to break the link between the inherent things and create new things to recognize. This topology-based cognition is the innate cognitive power that comes naturally, and people react most strongly when the topology changes. Great deals of experiments are needed to prove the existence of the process that visual cognition transforms into thinking. We will study the connection between the two kinds human activities from the experimental cases and compare the topology creative model with other creative methods, and find the advantages and disadvantages of this method.

**Conclusion**

This study on the topology of product shape aimed to define two pairs of relationships: the link between topological structure and product form, and that between priority attention and successful product design. In the case of the first relationship, the application of topological structure should be constrained under the law of product shape. Graphical representations of topological structure tend to be simple. Experiment 2 shows that methods or models for topological structures in product design can be formed. As for the second relationship, the advantage of adopting topological structures is priority attention, although this does not mean that a product shape adopting a topological structure is a successful design. However, with reference to the principle of beauty, form structure and topological structure may achieve seamless integration, and the connectivity, continuity, and compact visual expression exude formal beauty. Indeed, product design often uses a language of keywords, but turning keywords into visual image is a complex process (Y. Nagai et al., 2003 ). The keywords transformed into visual images by visual topological structures may be able to meet design requirements and gain priority visual attention. This involves the combination of vocabulary and organizational rules in the product form design. The form vocabulary still is the lines presenting for the keywords and the lines combine into topological structure. The use of topological structures in representing aesthetic impression, semantic interpretation, and symbolic association should also be examined toward the goal of making topology more natural and harmonious in product forms.

Abstract

The “Safety Grand Challenge” is a collaborative research project between the Royal College of Art (RCA) School of Design, and the Lloyd's Register Foundation (LRF). The maritime industry is dominated by “grandfathering” leading to a slow-pace of adopting innovations that can reduce risk and save lives at sea. We describe how impact was achieved through collaboration and design innovations that bridged the risk gap between technologies and human behaviours. Starting from the project brief we designed a collaborative platform that supported a constructive dialogue between academia and partner organisations that aimed to foster innovative design approaches to risk and safety. The project generated an engaged community with diverse expertise that influenced the outcomes which included seven prototypes designed by a group of thirty students from across the RCA. Throughout the course of the project the network extended to other partners beyond the initial ones that included the RCA, LRF and Royal National Lifeboat Institution. The “Safety Grand Challenge” demonstrates how research can be an explorative platform that offers opportunities to analyse and design solutions to real life safety problems in mature industries through the prototypes that reflect the sophistication of the project’s collaborations. Our conclusions support how design research helped identify the value of design for safety in tackling complex issues that intertwine human, environmental and commercial views and can shape new forms of collaborative research between academia and industrial partners.

Keywords: Design for safety, Action Research, Collaboration, Participation, Co-Design, Behaviour Change

Introduction

The “Safety Grand Challenge” is the first collaboration between the Royal College of Art School of Design, and the Lloyd's Register Foundation. It ran from August 2016 to February 2017. From the common intent to foster a new attitude and culture to reduce risk the two institutions agreed to explore how design can generate impact in the complex safety environment on water. Design is increasingly being incorporated in business models to encourage a creative approach to problems (Kimbell, 2009), understand the human factors and encourage risk (Kolko, 2015). However the influence design can draw from disciplines based on strategy, procedures and policies, like the prevention and intervention of risk, is still an emerging area yet be to be fully explored.

In the light of climatic fluctuations humanity needs to develop new strategies that both prevent and cope with events that endanger human life. The understanding of danger through the lense of design becomes an opportunity to grow resilient and creative human centred infrastructures that collectively understand risks through proactive methods. The “Safety Grand Challenge” research follows this overarching aim throughout. The project has been structured along two sub-projects: 1. Safe Ship Boarding- the exploration of a specific design safety issue that seeks solutions that improve safety for the ladders that
ship’s pilots and crew use to transfer from ship to ship; 2. Thames Safest River 2030 - a broader analysis of the river Thames in London aiming at the development of future strategies that make this the safest river by 2030.

**Literature Review**

Tackling safety on water in a combined design, research and teaching project resulted in two different requirements from existing literature and case studies; to inform the design research team of existing and emerging issues for strategic design for safety and a repository of research sources that could provide creative inspiration for the design research teams.

We looked at a framing model used by the engineering firm Arup (Arup & Rockefeller Foundation, 2015) to analyse and collect the data on global cities. Arup used four parameters to structure information and illustrate the content. These parameters function as guidelines for any further study on the topic (Arup & Rockefeller Foundation, 2015). Using this model as an inspiration we structured two bodies of literature for both sub-projects’ groups by dividing sources into five main topics and further sub-topics that could be navigated via two explanatory diagrams. We considered these diagrams as the transition point between research and teaching, as students explored the literature review through these structures. The diagrams were a quick and simple communication method that guided the students in the selection of the design directions to follow. As shown in the figure below (Figure 1) they list the ten themes which are divided in five per project; the first project’s topics are: Object and Products; Training and Education; Embedded Knowledge; Procedures and Regulations; Methods and Solutions. The second project’s topics are: Community; River Safety and Communication; Regulation and Innovation; Facts and Figures; Behavior and Experience.
Design for safety moves beyond the simple regulation of human behaviour around technology and we found several examples that highlighted collaborations tackling risk. An emergent approach to complex problems can be seen in the task force that led the post Hurricane Sandy interventions in New York (US Department of Housing and Urban Development, 2013) and the community of UN Habitat, which in the new Urban Agenda includes risk reduction as a factor to be considered in any global politics of urbanisation (UN HABITAT, 2016). These emergent risk-collaboration examples seek solutions that work across design, intervention and prevention achieved through the collaboration of different parties and disciplines. For instance “Rebuild by Design” (2014), the global collaborative platform lead by Henk Ovink, Senior Advisor to the former US Presidential Hurricane Sandy Rebuilding Task Force, under president Obama, tackles climate change issues from a different perspective (Ovink, 2016). According to Ovink looking at intervention only through built infrastructure is not enough in preventing natural disasters. On the other hand the expertise of diverse communities has power, strength and resilience to create a sustainable ecosystem which connects infrastructure through the exchange of knowledge. For Ovink people, and their knowledge, are the most sustainable response for facing the risk from climate related challenges. By launching design competitions Ovink designed a mixed community of experts and the general public through which he began a cultural change; government and communities changed their attitude towards climate related problems and, by doing so, they demonstrated first hand that it is possible to generate a new inclusive culture of safety that works through the relationship people establish with the environment enabled through technology.

Another project that tackles safety at an ecosystem level is the London Thames Tideway project (Tideway, 2017) which re-engineers safe working practices through new ways of
engaging experts, workers and the general public. Tideway is an ongoing engineering project that will channel the London sewage infrastructure below the level of the Thames river bed. The value of the project extends beyond the infrastructural ambition and by reclaiming the water, Tideway aims to bring Londoners back to the Thames, by transforming the river into a place to live, rather than a barrier between two banks. The method used to pursue such vision is the sense of community, ownership and membership, which is currently built upon a method that departs from conventional current health and safety culture. Tideway designs health and safety through the individual’s sense of membership and ownership, which equally applies to workers, engineers and primary school children. Members of Tideway staff participate and run workshops on health and safety, which are practiced as a core project activity rather than an add-on set of requirements. Health and safety is a core company policy designed-in specifically from the start with the intention to create an engaged community that any member owns and is part of by means of interactive participation. Health and safety workshops create a new culture of collaboration, which change behaviour through the sense of belonging.

A number of other sources provided insights in terms of behaviour and culture in relation to risk. Niedderer (2013) describes the ambition of shifting a culture of procedures to proactive behavior that supports responsibility via participation. Under this approach the perception of health and safety from a human’s perspective shifts: from procedures and policies to everyday’s lifestyle. Oltedal links the perception of risk to the cultural environment that people grow. Religion, society and beliefs play an important influence on the degree to which people perceive risks (Oltedal, et al, 2004).

In terms of human behaviour another important cultural aspect is described by ship’s Pilot Cpt. Chris Hoyle who during one of the project discussions underlined the high number of global ship’s crew who came from countries at the top end of the Hofstede (2011) power distance index. The power distance index describes the perceived distance between less powerful members and unequal authority in more powerful members. A high power distance index crew member may therefore be much less inclined to question a senior authority figure even when they feel there is a safety issue taking place. This can lead to a greater risk of accident and injury. Gladwell (2008) discusses how this feature led to a number of passenger aircraft crashes for one national airline and how the solution was a simple as changing the cockpit language to English due to its structure having a reduced number of deferential terms. Human factors including disciplinary language can become an issue. Syed (2015) contrasts the huge disparity between the aerospace and medical industries and cites the 1 in 2,400,000 deaths per flight worldwide in comparison to the 120,000 patients that die through medical errors in the USA per year in a recent Harvard University study. He traces this difference to the encouragement for pilots in a positive failure reporting culture so that others may learn, to the medical profession’s language rebranding, or cognitive dissonance (Festinger, 1957) of mistakes as ‘complications’ or ‘unforeseen outcomes’ and the lack of any automatic investigation when these issues arise. Whereas pilots can happily report errors in an encouraging environment, medical staff and Doctors often lose reputation and respect when failures occur. The differences between industrial and disciplinary attitudes to cultures of risk and failures can be profound and at the core of this is the collaborative ecosystem of technology and people. From these insights we developed a central position of recognising that design for safety has to go beyond the prescriptive legislating of human behaviour for technology use (and integrity) and the physical design of products and has to consider and embrace the wider ecosystem of culture, behaviours and expectations of people and technology.
Emerging Collaborative Methods

The open ended process we engaged with during the literature review phase helped gain valuable information and identify potential design strategies. As previously mentioned the contribution of the partners’ expertise in the project enriched the body of knowledge of design for safety and the role design can play in this specific area. As the literature review suggested the project should not be limited to built objects or infrastructure, we evolved methods based on participation and collaboration as the project progressed to support human infrastructure aimed at generating a resilient response intended as the capacity to “bounce back smarter, through collaboration, innovation and the best of science” (Ovink, 2016).

Our methodological approach was a combination of action research (AR) and participatory design research (PDR) with action research being the primary activity of the research team in navigating and developing the network of relationships and participatory design research explored by the teams who drew collaborators deep into their creative process and concept validation activities. AR acted as a guideline, PDR as exploration lens. Participation was used at different levels: the multidisciplinary academic research staff worked as a team to identify the literature review’s topics and content, focussed on design practice inputs with a state of the art review, field trips and reflective sessions based on project progress and insights; the student groups used a participatory design research-practice mode where they combined industrial strategic expertise from the Lloyd's Register with applied industrial experience from the RNLI (Royal National Lifeboat Institution), MPA (Marine Pilots Association), IMPA (International Marine Pilots Association) PLA (Port of London Authority) and CHIRP (Confidential Hazards Incident Reporting Programme). The stakeholders and experts participated in the project reviews regularly scheduled across the duration of the project and individuals partnered with specific teams. This methodology develop a hybrid approach (Foth & Axup, 2006) that suited both the research design practice elements of the project and allowed them to act together in unison as shown in Figure 2.

---

![Figure 2. Hybridised action research and participatory design research methods](image-url)
Designing for Safety

The design project phase began with AcrossRCA which is an intense week of activities and workshops where students from across the college work together in teams. Thirty students from different countries around the world and with expertises that span from engineering, fashion, sculpture, architecture, business, management worked in groups of three and four together on the grand challenge. Once the intensive AcrossRCA phase was completed the teams worked ‘long and thin’ up to the final exhibition and symposium at the Lloyd's Register Foundation Fenchurch Street building in London. During the reviews scheduled at different stages of the project stakeholders were invited to concept selection, concept development and design development stages. The exhibition displayed seven prototypes for saving lives at sea and the design researchers presented findings alongside presentations from the design teams to industry experts, safety bodies and project collaborators. These findings and industrial feedback were disseminated in the Safety Grand Challenge report (Hall, Ferrarello & Kann, 2017).

The perceived ownership of the project was crucial for the dynamics of the collaboration and to support the external partners’ confidence in contributing from their lenses of individual expertise. The perceived risk is that ‘naive designers’ who think they have the answers will alienate collaborators. From a participatory aspect the dynamics of the collaboration influenced the research methodology, hence the course and direction of the project through the feedbacks we gathered from the students’ project reviews and field trips’ meeting. We visited the PLA in Gravesend, boarded a Thames pilot boat to see at first hand river risks, the Lloyd’s Register Technology Center in Southampton, the RNLI Headquarters in Poole and Tower Lifeboat Station in central London. As evolved the design research process shaped our role as researchers, which consisted on the creation of a
common ground for innovation, i.e. the space where everyone, academia and industry, would dialogue and exchange information to identify possible solutions. Through the literature review and research methods we understood that risk is something based on the individual perception; for such a reason it was important for us to identify factors beyond technology. An important element we took into consideration was human factors and in particular the behaviour highlighted in maritime culture through the impact of ‘grandfathering’ (OED Online, 2017). In a ‘grandfathering’ culture information is passed on from one generation to another, thus shaping an environment that resists innovation and new practices; in such an environment external influences are something that is often perceived as “alien”. By participating in The Safety Grand Challenge experts, partners and stakeholders gained trust as well as excitement for new innovative solutions that could tackle cultural resistance. The excitement was particularly visible towards the end of the project, when the students received out of schedule invitations to exhibit the prototypes at an international conference organised by the IMPA at HQS Wellington in London, at the Lloyd's Register Technological Centre in Southampton and at the UKMPA Conference in Middleborough alongside planned exhibitions at RNLI HQ in Poole and commercial interests in developing and manufacturing one of the designs.

The industrial value of the safe ship boarding project was made by clear by Captain John Rose (CHIRP Founder) “You should be very proud of the achievements made with this project and with the students quality in their research, it has been an inspiration to me and to several others involved.” and also from Susan Cianchetta (Thames Strategic Review co-author) who noted the new innovation methods “It's been a pleasure to work with you and the teams on such a new and interesting approach to problem solving.” The Lloyd's Register distributed the prototype images to its global marine network. We received comments from around the world, which include a pilot from Houston USA who wrote: “These are all good ideas, each is unique and has identified a specific improvement to the current system in use”. He also added “I am pleased to see our organization engaged in these type of initiatives”.

**Reflecting on Collaborative Risks**

The “Safety Grand Challenge” overarching themes focussed on risk, design and safety on water. Nonetheless the challenges extended beyond this list as we had to develop methods to interface the complex environment created through the themes. For this reason the early research tended to narrow down the number of elements to take into consideration even though we were open to creative detours and encouraged different areas to the ones suggested in the literature review themes. The two aspects students had to be aware of were communicating clearly the design aims and considering the potential impacts in a complex design field with many interacting elements.
The role of the design researchers was in developing the infrastructure that would link and manage the dialogues among the parties. The hybrid combined methodology of AR and PDR created the common ground for innovations that supported the exchange and transferability of knowledge through the engagement of the different stakeholders. Through exposure to the challenge shaped by first hand experience students framed the issues from different perspectives which in their turn informed the design process. However because of the combined aspect of teaching and researching in collaboration with external partners we encountered communication challenges which didn't intrinsically concern designing but could create confusion and lack of clarity in the group. One of these was language. We had ships pilots, captains, chemists, designers, historians, architects, mechanical, aeronautic, electronic engineers, products designers and service designers. To keep every party engaged at an equal level we had to carefully consider the different interpretations of the design scenario from a language point of view whilst making sure that skills and expertise would be free to contribute to the project. For this reason we adopted methods that would work in an interdisciplinary context; through a brainstorming workshops students produced up to 100+ ideas per group in a two hour session. This was achieved by using design innovation techniques including character and context cards and design exorcisms alongside more conventional rules such as not discussing ideas, speed not quality, copy and improve and no judging etc.
The brainstorm workshop was the first step in the design process which led to the final seven prototypes which “visualised” the value design for safety can deliver. By tackling aspects that span from communication to equipment and technology, the seven prototypes make design a strategic medium that operates through tangible objects. Objects are “interfaces” that address problems through practice-based solutions. As students directed their thinking into the themes and topics, their design approach kept the large and small scale concerns in parallel. Students understood the complexity and multiplicity of the context and produced prototypes that spanned strategic and detail scales.

For instance one of the ladder prototypes Dynaweb (by designers Chia Cheng Kung, Chih-Hsing Huang, Irene Chiu and Nick Hooton) focused on innovating the manufacturing aspect of the ladder to improve weight, storage, maintenance and transportability by introducing rapid prototyping technologies that reinvent the joinery and flexibility of the traditional pilot ladder. If the final design upgraded the current ladder design that has changed little in 300 years (Hignett, 2012) to a supercharged contemporary design using state of the art materials and manufacturing processes. Through observation, collaboration and external partners’ mentorship the group understood that innovation could be introduced in the behavior of the ladder under stressed provoked by the harsh environmental conditions it is normally exposed to ranging from +50 to -40c. Dynaweb rethinks joinery through a generatively designed composite flexible-rigid behavior that allows the ladder to flex and be stored easily. In addition the flexible-rigid ladder is much lighter that the current design. As the group understood the importance of the pilot’s perception of solidity, they also designed the ladder visual interpretation through shape and colouration. This was achieved through a collaborative design process including expert ship’s pilots, the RNLI and Lloyds Register.

Calm Object Remain Calm for Help (CORCH) developed the architecture of a videogame
as a training class for young adults that the RNLI could use in multiple locations. However, the use of a videogame for safety issue could increase risk as participants become better at the game. This could result in overconfidence and lower their perception of risk. To avoid this condition the group of designers (Linh Pham, Simon Cundall and Jennifer Haugan) introduced random variables in the code, which affect the environmental conditions of the VR game so that each experience is unique. At the end of the game each player gets a score and RNLI approved certificates. Score achievements make the player an ambassador of different grades and in charge of sharing and developing knowledge to virtual and physical communities.

Project Sea Pilot’s Assistant (SPA), (Jingyi Wu, Marcus Comaschi, Yu Li and Jen Hsien Chiu) brings social network thinking and new technologies into the maritime sector by producing a pilot version of TripAdvisor. Each pilot using a ladder can report accidents, damage and crew behavior in the app. The availability of real time information in digital format makes pilots boarding the ship at the next port aware of any problems. At a strategic level the app is linked to a modular ladder system to tackle two existing problems: (1) the ship’s crew already buys the ladder in parts, (2) there is a lack of knowledge of repairing the crafted old ladder which can’t be safely repaired without a level of training. To incentivise the use of the ladder worldwide the group trademarked the modular ladder with the a certified logo. From a strategic design perspective the combination of the app and the modular ladder allows the group to develop an R&D platform based on direct live feedback as a result of collaborative design embedded in the risk environment and using regular industrial expertise and feedback. SPA is a project that understands people’s behaviour and the environment they are in by using technology as a shareable and collaborative interface.
Throughout the Safety Grand Challenge we had the opportunity to test a different collaborative research approach for tackling design for safety on water. This emerged from the evolution of the project. We transformed the constraints of the physical output to motivations and opportunities to find solutions that would work in a real world scenario. Although faced with very tangible real life design safety issues the design teams were not limited to current problems and engaged with the deep knowledge we provided to understand how projects could positively impact stakeholders from different perspectives. Each group looked at future developments in different industries, from business models to multisensorial digital environments, communication and new materials and manufacturing processes. By mixing seminars, workshops, field trips and the literature review we allowed the designers to appreciate the complex nature of the scenarios, which helped to give a good picture of the composition and dynamics of the existing situations. Design is particularly open to failure in the creative phase (Hall et al 2016) and this can be an advantage when aiming to bring new thinking to complex design safety challenges. However encouraging failure when tackling design for safety can be seen by some as increasing project risk.

A strong motivation for students was the deep immersion in field trips to the RNLI headquarters where they went out on a lifeboat to get a ‘pilot’s eye view’ of ship boarding,
a visit to the PLA Vessel Traffic Service (VTS) centre in Gravesend Reach and a trip on the River Thames with expert crew who pointed out waterborne safety risks. Everyone learnt by doing, and students achieved confidence and a clear knowledge of the topic. We believe that the practice-based research model developed for the project, has shown to be capable of fuelling a variety of inputs to the diverse groups of people that participated in the research. The strength of the project became the collaboration, which has shown to be effective in allowing diverse multi-disciplinary design teams to engage meaningfully in a complex design challenge and deliver outputs worthy of serious consideration by industry experts (Hall, Ferrarello, Kann, 2017).

Conclusions

In summary we conclude how the collaborative “social platform” we built around the project through design research offered a wide range of parties from academic researchers, student design groups, NGO’s industry bodies, maritime agencies and individual experts a space to work together and engage. From the complexity of the existing context made up of a resilient culture of “grandfathering” and cultural challenges of power relationships along with a group of industry experts unfamiliar with design and academic processes, we tackled the problem and made complexity a strength by offering new insights through the collaborative relationship between design and safety. By establishing a common ground between academia and industry, we made design a social platform that enables people of different backgrounds to participate in risk reduction by combining knowledge gained from practice and theory. To enable this model we had to engage as participant researchers and directly collaborate with the organisation, field trips, teaching and building relationships with the partners. We believe that such an approach achieved the engagement aspect of the project the Lloyd's Register Foundation hoped to initiate in exploring the value that design led innovation could bring to safety through a grand challenge format.

From the first meeting, where one industry expert showed hostility to the idea of an ‘art college’ working on something they believed to work adequately, we managed to blur boundaries and build porosity across different fields (Sennett, 2013) to bring a wide range of views onboard to work with us and the team of students. This was a necessary step to enhance the value that design can bring to risk reduction and safety. Our ambition was to move beyond the existent engineering practice of safety, where strategic planning and risk assessments are structured on the base of scenarios; where risk is viewed as a mechanism made of events; where a group of experts define the risk scenario procedures, and where the user's role is to follow those procedures with a limited form of engagement and understanding. With this project we understood that risk is a very complex and dynamic environment; factors that increase risk are defined by entropic scenarios whose complexities and dynamics shift in real time. We define entropy here taking the second law of thermodynamics that systems tend to complexity and chaos and in the same way that design has a proven success in tackling wicked problems (Rittel & Webber, 1972); we suggest that it can also tackle the entropic scenarios of safety on water. As any entropic phenomena, where all variables present in the same environment have equal probability of configurations by chaotic relationships, risk related variables behave similarly. There is not a hierarchy that runs configuration of risk; all factors involved in risk play the same importance and it’s the combination that makes the difference.

By working with partners and students, we understood that safety is achieved by strategically planning prevention over later intervention. We highlight that the combined
collaboration of human factors including both physical and psychological plays a pivotal role, as human behavior can tackle risks. Behaviour can indeed adapt to environmental conditions and creativity reacts to that potential; hence design plays an important role. Through the students prototypes we demonstrated that by the observation of existing conditions, behaviours, trust, education, awareness and attitudes it is possible to frame risk into a combined physical-psychological design solution. By engaging other design related disciplines - like manufacturing, communication and user experience - the prototypes display design interventions that reduce risks; the final outcomes are not products but demonstration and visualisations of risk that offer solution that think ahead.

In our research design and safety shaped a creative territory that assessed risk under co-responsibility and collaboration. Design is the interface of communication between the parties which enables mutual understanding through creative thinking. It is a dynamic risk mediation process which makes any involved party responsible of action and intervention in the case of danger. Given the unpredictability of risk, which often happen in small time frames through the methodology of this project we understood that being creative and taking responsibility might be the method where design and safety find a common territory. Design for Safety doesn't aim to create another set of rules to observe, it can offer a holistic infrastructure of possibilities or a taxonomy of problems (Dorst, 2017) that maps the issues it aims to solve, thus influencing the direction of an event and preventing future risks. Design for Safety is an approach that mediates entropic situations. It engages the complexity of event rather than simplifying them to a set of reduced factors, specifications or criteria which might not take into account the micro-elements that contribute to increasing the level of risk. There is no single procedure that can comprehensively tackle future risks, however a deeper creative understanding of specific situations might reverse the emergence of new risks and contribute to safer experiences and livelihoods for those enjoying leisure activities and working on seas and rivers around the world.

Abstract

Over the last two decades, constructive design research (CDR) — also known as Research through Design — has become an accepted mode of scholarly inquiry within the design research community. CDR is a broad term encompassing almost any kind of research that uses design action as a mode of inquiry. It has been described as having three distinct genres: lab, field, and showroom. The lab and field genres typically take a pragmatic stance, making things as a way of investigating what preferred futures might be. In contrast, research done following the showroom approach (more commonly known as critical design (CD), speculative design, or design fictions) offers a polemic and sometimes also a critique of the current state embodied in an artifact. Recently, we have observed a growing conflict within the design research community between pragmatic and critical researchers. To help reduce this conflict, we call for a divorce between CD and pragmatic CDR. We clarify how CDR and CD exist along a continuum. We conclude with suggestions for the design research community, about how each unique research approach can be used singly or in combination, and how they can push the boundaries of academic design research in new collaboration with different disciplines.

Keywords: constructive design research, pragmatic constructive design research, research through design, critical design, speculative design

Over the last two decades, constructive design research (CDR) — also known as Research through Design — has become an accepted and popular mode of scholarly inquiry within the design research community and in human-computer interaction (HCI) [Koskinen et al., 2011; Zimmerman and Forlizzi, 2014]. CDR is a broad term encompassing almost any kind of scholarly research that uses design action as a mode of inquiry; researchers make things as a way of producing valuable new knowledge. CDR values both thinking and making. We believe CDR has become popular because 1) it addresses challenges that cannot easily be approached with scientific or engineering inquiry, and 2) researchers trained in design find CDR to be a ‘natural’ way to conduct research. Koskinen et al., [2011] note three distinct genres: lab, field, and showroom.
The lab and field genres typically take a pragmatic stance, making things as a way of investigating preferred futures. Research done following the lab approach often involves a behavioral theory or design philosophy meant to improve design (e.g., using ethics to drive aesthetic choices for interaction [Ross and Wensveen, 2010]). Researchers make things operationalizing the selected theory or philosophy, then conduct studies to see if the artifact produces the outcome they intend. Research done following the field approach usually begins with fieldwork investigating a target audience, problematic situation, or context. Researchers make things designed to bring about a specific change, and they place these objects back in the field to assess if they have the desired impact (e.g., studying people’s TV watching behavior and suggesting interventions to make it a more social experience [Hassenzahl et al., 2013]). Research done following the showroom approach typically functions as a critique of the current state of the world. Known more commonly as critical design (CD) [Dunne, 2008], and more recently as speculative design and design fictions, this type of research works to generate a debate about values and hidden issues that researchers feel are both critical and missing [Dunne and Raby, 2013; Bardzell and Bardzell, 2013].

We claim that CDR is being damaged due to increasing and unnecessary conflict based on a misunderstanding of its aims. Interestingly, this conflict does not come from design studies researchers, nor has it come from engineers and behavioral scientists working in HCI. The source of the conflict is internal, taking place within the groups of researchers engaged in CDR. The conflict exists between a pragmatic push for relevance and a critical push back for more freedom in what design research can and should be. Those reviewing CDR papers all too frequently adopt the wrong lens. Reviewers look for pragmatic relevance from work that should be judged based on the quality of polemic it produces, and critical reviewers dismiss work for being too applied and not taking intellectual risks. Discussions of research approaches have also been contested. Pragmatic CDR researchers have pushed for more rigor in the hope of increasing the impact of pragmatic contributions and CD researchers have pushed back, noting that a forced scientific evaluation would significantly limit the kinds of research designers can do [Zimmerman et al., 2010; Gaver, 2012].

The conflict is familiar to those in design schools, where a product designer’s pragmatic, problem-solving lens can conflict with the artistic lens of fashion and furniture designers. This conflict feels similar to the conflict in the sixties between radical designers and contemporary, apolitical designers, who were content to advance designs without connecting advances to utopic political foundations [Branzi, 2010]. These previous conflicts have generated a culture in which both arguments co-exist and create fruitful competition rather than polarize discourse and discontent. To help transform this conflict into a productive situation, we call for a divorce between CD and pragmatic CDR. Explicitly differentiating these two types of CDR will reduce the internal conflict among design researchers. We also propose that we place these two types of design research on different ends of a continuum, showing how design research efforts can encompass varying combinations of these two approaches. We feel that this placement will allow each research approach to be strong and unique and to have its own criteria for evaluation.
To facilitate this goal, we provide a brief history of each approach, focusing on aspects of key projects. We articulate the knowledge outcomes from each approach, and what we see to be the strengths and weaknesses of each. We show how a design research effort can encompass varying combinations of these two approaches. We conclude with suggestions for the design research community about how to grow CD and CDR as unique research approaches and to continue to push the boundaries of academic design research in collaboration with new disciplines.

**Constructive Design Research: The pragmatic side**

CDR uses *design action* as a mode of inquiry. Researchers following this approach employ processes from design practice. When working on the pragmatic side of CDR, researchers make artifacts in order to codify understanding of the current state and to suggest how a design solution will yield a preferred future state. This approach has been described as distinct from scientific inquiry and engineering inquiry, because 1) it addresses a subjective question of what is ‘preferred,’ and 2) it allows designers to create new knowledge while they undertake processes inherent to design [Zimmerman, Forlizzi, and Evenson, 2007]. The pragmatic side of CDR operationalizes theory or philosophy that discusses design as focused on achieving a preferred state [Simon, 1969]. It takes into account the idea that many societal problems cannot be approached from the reductive methods of science and engineering and would best be approached with *design thinking* [Rittel and Webber, 1973]. It describes design as a reflective process utilizing abductive reasoning to reframe problematic situations as a way of making an advance [Schön, 1984; Kolko, 2010; Dorst, 2011].

Over the last two decades, this research approach has gained increasing acceptance in the design research community, making a new type of knowledge contribution that does not fit within the traditional definition of design studies [Koskinen et al., 2011]. It has also gained acceptance in the human-computer interaction research community, which brings together engineers, behavioral scientists, and design researchers.

**Lab**

Researchers following CDR’s lab genre typically hold design workshops to investigate a behavioral theory or a philosophical idea. Design activities in the workshops reveal underlying patterns in how a theory, philosophy, or design quality might best be embodied in an interactive product. Researchers then produce several versions of the same artifact and typically run controlled studies to assess their insights about the artifact.

The lab genre emerged in design schools in the Netherlands because these schools integrated experimental psychologists and designers into faculty and student bodies. This genre blends the controlled experimental approach to research found in psychology with design action and insight. One example of the lab genre can be seen in the research of Stephan Wensveen, who built an alarm clock that was meant to understand emotion expressed through action and interaction with the clock (Figure 1) [Wensveen, Overbeeke, and Djajadiningrat, 2002].
Figure 1. Lab research in the form of an alarm clock that recognizes the emotions of its user from rich interaction. [Wensveen, Overbeeke, and Djajadiningrat, 2002].

CDR lab research advances the discipline by providing new ways for designers to embody important qualities in new designs. The resulting artifacts work as both exemplars and as evidence. The empirical evaluations of the artifacts provide evidence of how people react to the new qualities and reveal complications in moving from theory to thing. In many cases, researchers create frameworks that detail how the theory under investigation can most easily be operationalized in a design. The resulting knowledge aids other design researchers and design practitioners by providing details on how they might draw these new qualities into their work. When reviewing lab-based work, reviewers should assess the impact and advancement to the field of design research. The designs are not intended to be early versions of commercial products. The work should not be assessed based on perceptions of how well the designs might perform in the market.

Field

When following the field genre, researchers typically select a target audience or context and then conduct fieldwork with the aim of discovering opportunities for new products or services to improve people’s lives. Through a synthesis of the data, researchers reframe the problematic situation and draw out insights, opportunities, and concerns. They make new artifacts meant to achieve a preferred future and place them back into the environments of the field study in order to assess their impact. The field genre emerged from participatory design and from action research. It mixes design action with sociology, anthropology, psychology, and engineering.

The project on Families, Control, and the Smart Home provides an example of the field genre. Researchers conducted extensive fieldwork investigating the challenges faced by
dual-income parents. The researchers reframed several aspects of smart homes [Davidoff et al., 2006]. First, they focused on home as less of a place and more a set of responsibilities and social roles. Second, they recast the goal of the smart home technology as “making families feel in control of their lives,” in contrast to typical smart home research that focused on control. The team addressed the anxiety many dual-income parents felt about forgetting to collect their children at the end of the workday, a problem made more acute when parents took over each others’ routines. The team developed a system that learned a family’s pick-up and drop-off routines. It used these inferences to issue alerts when there was a child that likely needed a pickup and no parent appeared to be heading in the correct direction (Figure 2) [Davidoff et al., 2011].

CDR field research views the reframing of a problem or design opportunity as the main research contribution. This focus on reframing subtly changes how researchers engage in the fieldwork that informs their designs. Instead of working like an ethnographer to develop a detailed understanding of the present, CDR field researchers work to develop a “good enough” understanding of the present that drive imagination of a preferred future [Odom et al., 2012]. CDR field research always has some kind of investigation of the present to support an articulation of the future, and occasionally the research stops at this point, with no resulting artifact. In most cases, however, the artifact made following the fieldwork functions as an exemplar of the problem/solution framing. Artifacts get evaluated in terms of how well they address or advance the reframing. Like CDR lab research, researchers following a field approach often produce frameworks to help researchers and practitioners work with the new problem framing. Artifacts made following a field process are almost never intended to be commercially viable; however, they are meant to inform the design of viable products that embody the reframing.

Figure 2. Field research on families and smart homes. The Person-Place-Time-View interface shows a prediction of where and when every family member will be and which parent is responsible for different child pickups and drop-offs.
Lab and Field: Shared pragmatics

Lab and field share a pragmatic perspective. These approaches attempt to make a specific and explicit change in the world by producing knowledge researchers and practitioners can apply in future work. They draw on disciplines including psychology, sociology, anthropology, and engineering, but they also make a designerly contribution. They use theories of human behavior, but the research typically does not advance these theories by refining or refuting them. Assessment mainly revolves around relevance, but includes novelty, rigor, and validity. Relevance connects with the intended impact the work is attempting to have on the world. Novelty requires that the work offers new insights or even a complete reframing. Rigor connects with execution of research methods as well as design craft. Validity relates to both the overall design of the research study, including the selection of the methods, and in providing a description of the design process that others could reproduce.

Critical Design: Definition, history, and examples

CD — by which we mean design research known as critical design, speculative design, or design fictions — is a type of design research that involves making artifacts that are intended to reveal hidden values and generate debate. It draws on traditions from art and the humanities, and it often uses strategies such as hyperbole or irony to communicate a point that is disconnected from the artifact that has been designed.

CD has several origins, but the name “critical design” comes from the book Design Noir [Dunne and Raby, 2001]. One specific purpose of CD has been to separate design from its tight connection to commercial practice. While design discourse has also discussed a need for this separation, CD represents a research-based attempt to revise the meaning and purpose of design from within.

Design Noir provides a nice example of CD research, telling the story of Placebo project, which explored how people relate to electromagnetic radiation (EMR) around them [Dunne and Raby, 2002]. Researchers designed a series of simple, non-functional prototypes people might use detect EMR and thus protect themselves from its invisible force. (Figure 3a). These functioned as placebos — the prototypes did not protect people, but they did create debate around EMR and cultural attitudes towards it.

Figure 3. Examples of CD: a) EMR Probes [Dunne and Raby, 2002]; b) Slogan Bench [Gaver, 2002]; c) Datacatchers [Gaver et al, 2016].

In our analysis of examples, we view the Presence Project as a turning point for CD. The
Interaction Research Studio at the Royal College of Art’s work on Presence shows a transition towards design research. The group’s designs featured technological components, both in early projects like the Slogan Bench (Figure 3b) [Gaver et al, 2001] and continuing to recent work like Datacatchers (Figure 3c) [Gaver et al, 2016]. The Presence Project showed how design research can reject a scientific approach and still be systematic. This is consistent with later publications that described the aims and premises of CD as aesthetic accountability rather than as scientific [Dunne and Raby, 2001; 2013; Blythe, 2014].

Dunne’s research explorations often took the form of concepts provoking thought about where scientific advances might lead society. This work developed a powerful advocate in Paola Antonelli, the design curator of New York’s Museum of Modern Art. The exhibition Design and the Elastic Mind at MoMa brought CD to the attention of the art world. At this time, the methodology behind critical design also shifted. Instead of critique, it turned to the exploring various types of possible futures. Design became speculation, and its criticism was now implied rather than direct. In recent publications, Dunne and Raby have likened design to literature, aligning their CD work with the notion of design fiction [Dunne and Raby, 2013].

The Interaction Research Studio continued its work when it moved to Goldsmiths College, designing artifacts to provoke thought and debate about new futures for technology. The approach for this work followed from the Placebo project in Design Noir. CD promotes design as a powerful force for change in the world, one that is distinctly separate from market-driven change. CD makes these arguments through design artifacts rather than philosophical discourse. It has a theoretical foundation, as Dunne’s PhD thesis clearly shows [Dunne, 1999].

Bardzell and Bardzell [2013] recently noted a problem with CD in the relationship between designing and discourse. They argue that the criticality of CD lies more in the discourse than in the design artifacts produced. Without the artifacts, critical design would not exist; however, a reliance on writing keeps the approach going and growing. Unlike art, whose artifacts function as vehicles for thinking, CD has become well known for its attitude, published papers, and presentations within academic and scholarly settings.

CD brought practices from art and the humanities into design, and produced a discourse centered around design artifacts. This approach stands in opposition to commercial design practice. CD and CDR treat the integration of social science and engineering differently in their approaches to work (see [Bernabi and Power, 2016] for one exposition of CD). CD artifacts are often built with an avant-gardist aesthetic to set them apart from commercial products, which gives this form of research an implicit, political critique. References are used in CD to build up designs, rather than to evaluate them critically or to contextualize the designs systematically.

We believe that CD research would benefit from further documentation and from more discussion of its unspoken assumptions and their implications to design research, and by extension, design education. We believe that the main differences between pragmatic CDR
and CD lie in these assumptions. CDR appears more open and flexible in its assumptions than CD, which rejects science and prioritizes artistic expression. In doing so, it reduces the many alternatives for seeing design as a source of knowledge. For example, it devalues interpretive social science in design, while we see it in the lab and field genres. Finally, CD prioritizes the avant-garde aesthetic at the cost of more contemporary alternatives. Most of these limitations are not logical necessities, but instead seem to be more historical traditions of CD.

**Strengths and weaknesses of CD**

The brand and cachet of CD is alluring, especially to those who are new to design research. CD connects to roots in art and in design thinking. CD’s demand for high aesthetic quality of artifacts also works as a strength; this makes outputs of CD easy to differentiate from design practice, something that cannot be said for CDR.

CD suffers by not clearly articulating the kind of knowledge it produces, and how this knowledge matters to anyone other than other CD researchers. Often, the outcomes of CD offer few connections to the larger design research and practice communities. This is partly because there is no consistent means of documenting these types of projects (although [Gaver and Bowers, 2012] offers a starting point), and partly because CD works more like art in its tendency to keep its references hidden. CD produces knowledge through sensitizing concepts and innovative methods; however, it is not always clear how other designers can take up and advance this knowledge. Finally, CD is at odds with any type of design that works towards social innovation, because it focuses on the designed artifact as an expression of the designer, rather than attempting to address the needs of other stakeholders.

**Time to Divorce?**

We feel the time has come to ask for a divorce between pragmatic CDR and CD. Conflict is counterproductive for any research community. Developing two sets of objectives, goals, and knowledge outcomes for each approach should reduce the number of inappropriately rejected papers, resulting in both more research output and in better quality research. A separation between these two different ways of making things to produce different design knowledge will allow each to grow and develop their own knowledge outcomes, standards for evaluation, and outstanding research contributions.

However, we do not see these approaches as being exclusive. Instead, we propose to place them on a continuum, to illustrate that any singular research effort can include aspects of both approaches (Figure 4). Most research falls near the ends of either poll, but some projects fall more squarely in the middle, working to critique the current state of the world and offer a pragmatic vision of preferred futures.
Figure 4. CDR and CD are two distinct research approaches, but can be placed on a continuum to indicate that any single design research effort can incorporate aspects of both approaches.

### Similarities and Points of Conflict Between pragmatic CDR and CD

While CD and pragmatic CDR draw from different traditions, work with different intentions, and produce different kinds of artifacts, they share an overlap in much of the kinds of knowledge they produce and in the underlying structures that lead to better quality research. It is the ideology and purpose that differentiates the two approaches, and therefore, how design and research processes unfold within each. One research approach may follow the other, or they may be undertaken concurrently. For example, the work from TU/e mentioned in the CDR section [Wensveen, Overbeeke, and D)ajadininggrat, 2002] started with probes, then ended with lab studies. The Datacatchers project started as a critical design effort, but ended with a systematic evaluation [Gaver et al, 2016]. We see Odom’s work on the PhotoBox, investigating slow technology and interaction with people’s growing collections of virtual possessions, as an example of work that unites these two distinct perspectives [Odom et al, 2014].

Pragmatic CDR and CD both produce knowledge in the form of the resulting artifact [Cross, 2001]. Knowledge in this form can be particularly valuable in transferring ideas to practice as design practitioners most often share knowledge with each other and teach through a discussion of exemplars. Early HCI research noted that the thing must proceed the theory of the thing, such as the mouse arriving before the usability research showing that it functioned as a great pointing device [Carroll and Kellogg, 1989]. Recent CDR research has discussed many different ways of formalizing this artifact knowledge. Researchers have discussed analyzing artifacts within a program using frameworks [Zimmerman and Forlizzi, 2014], design patterns [Zimmerman, 2009] and strong concepts [Höök and Löwgren, 2012] that rise above the details of patterns and function more as intermediary themes. More recent work by Dalsgaard and Dindler [2014] introduce the idea of bridging concepts that build on observations of new interaction techniques that emerge across several designs both within and outside of a research team’s portfolio. These are different from design patterns in that they are linked by an underlying behavioral theory, which brings different interactions together.

Additionally, work by Brandt and Binder [2007] discusses the importance of a research program. This is a larger project that encompasses individual design cases and design experiments. A program works well when it links findings and insights from cases and experiments. A program forms a larger argument and connects the research being done to larger questions or concern within a research community.

In its part, CD has seen debate as a key mechanism for extracting knowledge out of
projects. This notion came originally from Dunne and Raby [2001], who encouraged designers to point out alternative ways of seeing things and found its clearest formulation in the Material Beliefs project [Beaver et al., 2009]. Some recent work leverages long-term field studies and brings CD closer to fieldwork in CDR [Odom et al. 2014]. Other work has created a bridge by discussing how design researchers might document a research program in the form of an annotated portfolio [Gaver and Bowers, 2012]. The structure that a program provides benefits both pragmatic CDR and CD research by creating environments where tacit knowledge learned in a specific design case has the opportunity to become more explicit in future cases.

Points of Conflict

Design researchers working in pragmatic CDR and CD increasingly seem to find themselves caught up in non-productive issues in advancing their work. These issues include impact and peer review of new research, efforts to formalize research approaches and establish research priorities, and efforts to obtain funding.

Some pragmatic CDR researchers complain their work lacks the impact they desire. They note that the engineering and behavioral science researchers in the HCI community almost never build on the knowledge CDR researchers produce. Impact can also be hindered through the peer review of design research publications [Zimmerman et al, 2010; Gaver, 2017]. Too much of the discussion on what it is that makes a good CDR or CD contribution takes place in private, and this make the review process feel random and arbitrary. Advances in the field that take place in the actions of individual reviewers or in the private discussions of program committees where academic papers are accepted or rejected are generally not shared with the larger design research community. A recent article bemoaning the lack of “real design papers” at CHI, an HCI conference that has given rise to much CDR activity, points to a potentially unintended outcome of this conflict [Gaver and Hööök, 2017]. Pragmatic CDR has created a set of quality criteria to guide the design research community in formalizing what constitutes a good CDR project [Zimmerman, Stolterman, and Forlizzi, 2010]. The goal is to create high-quality contributions that are on par with the best contributions from other research traditions, thus legitimizing design research beyond the discipline of design. Other work has set forth criteria that describe a high-quality pragmatic CDR contribution, including process, invention, relevance, and extensibility [Zimmerman, Forlizzi and Evenson, 2007].

These criteria can be used by others in planning and executing their own CDR efforts to guide them in creating quality contributions. However, these are not meant to be applied to CD cases, which puts premium on novel perspectives rather than findings. It is clear that the criteria developed to describe a good pragmatic CDR contribution do not fit CD. While process and relevance may be viable criteria for both pragmatic CDR and CD, concepts and artifacts developed in CD are rarely meant to be generalizable. Rather, they are like pieces of conceptual art – meant to expose unconsidered assumptions and ideological commitments in existing practices.

Finally, when applying for grants from government agencies or from industry, design research is often met with some suspicion in terms of the methodology, with concerns that
the insights gained will not generalize or scale to larger populations. In trying to address these challenges to make the work more impactful and fundable, some pragmatic CDR researchers have pushed for increased rigor, increased relevance, and the development of theory as an outcome of CDR [Zimmerman, Forlizzi and Evenson, 2007; Zimmerman, Stolterman, and Forlizzi, 2010]. Not surprisingly, some CD researchers have pushed back. They note that applying a scientific lens to CDR research will diminish the breadth of design research. They resist the creation of any “official” standards for evaluating CDR research, even though they note the lack of evaluation standards may be the cause of substandard research, and naïve design, being published.

Discussion

We have described the origins, practices, goals, and knowledge outcomes of two types of constructive design research that are currently locked in a non-productive conflict. We believe that now is the time for the broader design research community to divorce the practices and knowledge outcomes of pragmatic CDR and CD. We see three main activities in this effort: 1) developing “individual brands” for CD and pragmatic CDR; 2) increasing the quality of these efforts without narrowing the space of investigation; and 3) developing approaches to teach about DR in both professional and academic settings.

With minor efforts, the design community can develop a distinct brand for individual forms of constructive design research. For example, CD could be branded in a way that anchors it in design and makes it distinct from art, maybe by building on Dunne and Raby’s repeated efforts to draw this line [see Dunne, 2007]. Pragmatic CDR could be branded in a way that makes it distinct from design practice. The design research community should always strive to increase the quality of its efforts without narrowing the space of investigation. Much could be accomplished with some simple efforts such as documenting investigations in detail, better articulating aspects of the process that in hindsight were found to be critical to the progression of the research, and being aware of and using others’ design theories and frameworks when available. These activities are also important when designing things that do not yet exist, when there is little understanding of how future products, services, systems, and environments will situate in the world, and for larger societal problems, which may have many alternate solutions.

A final effort is for the design research community to develop approaches for teaching novice researchers about CD and pragmatic CDR, the strengths and weaknesses of each approach, and when and how to apply each in a research setting. In both CD and CDR, the goal is to grow the research approach and to extend the boundaries of academic design research to new efforts and contexts. The field needs the diversity of many approaches, and this divorce will help our community grow and become more impactful.

Conclusion

Through history, influence, and approach, pragmatic CDR and CD have grown into separate, unique constructive design research approaches. Our goal in this paper, through examining the history, practice, goals, knowledge outcomes, and strengths and weaknesses
of each approach, is to increase awareness and influence of all design research contributions. We call for a divorce of pragmatic CDR and CD. We hope that in the future, CD and CDR will be as commonly known and as viable as other historic movements in our discipline.

**Jodi Forlizzi**

Jodi Forlizzi is a Professor of Human-Computer Interaction in the School of Computer Science at Carnegie Mellon University and a Co-founder of Pratter.us, a healthcare startup. She designs and researches systems ranging from peripheral displays to social and assistive robots. Her current research interests include designing educational games that are engaging and effective, designing services that adapt to people’s needs, and designing for healthcare.

**Ilpo Koskinen**

Ilpo Koskinen has been working as a professor in industrial design since 1999 mostly in Helsinki, but also in Denmark, Australia, and Hong Kong. His main research interests have been mobile multimedia, design in cities, and the methodology of design research. His recent work expands his earlier work on constructive design research into social design. His mission is to expand design by making research that communicates to designers.

**Paul Hekkert**

Paul Hekkert is full Professor of Form Theory at Delft University of Technology. Paul conducts research on the ways products impact human experience and behavior, and leads the international project UMA (Unified Model of Aesthetics). He is co-editor of *Product experience* (2008) and published *Vision in Design: A guidebook for innovators* (2011), a book that describes an approach to design and innovation. Paul is co-founder and chairman of the Design and Emotion society and captain of science of the Dutch Top Sector for the Creative Industries.

**John Zimmerman**

John Zimmerman is a Professor of Human-Computer Interaction in the School of Computer Science at Carnegie Mellon University. He teaches courses on interaction design, service design, HCI, and innovation. His research investigates four areas: (i) interaction with intelligent systems, (ii) service innovation, (iii) crossing the digital-physical divide, and (iv) research through design as a scholarly approach to inquiry.
Design for Social Innovation – Digital Technologies and Local Communities

Teresa Franqueira, Universidade de Aveiro, Aveiro, Portugal, teresa.franqueira@ua.pt
Gonçalo Gomes, Universidade de Aveiro, Aveiro, Portugal, goncalo@ua.pt

Abstract

The use and democratisation of new digital technologies have given visibility to groups of people and grassroots organizations that can be considered agents of change in the transition to a more sustainable world. Design plays an important role in the definition of strategies and in the development of innovative solutions to tackle some of the contemporary problems society faces. This paper aims to show several projects developed over the last 5 years in the subject Design for Social Innovation at the Master in Design and the Master in Engineering and Product Design at the University of Aveiro, and its relation to the new social media and technologies. By using Service Design tools to improve Social Innovations and the integration of new digital technologies, we design new and improved solutions to foster sustainable development. The creation of a DESIS Lab has also allowed to develop innovative design solutions within local communities. The methodology used is based on Learning-by-Doing with an important and relevant initial phase using ethno-graphic methods. The results are showed as academic projects that can be applied and replicated in different contexts.

Keywords: Design. Social Innovation. Service Design. Social Internet of Things. DESIS Network. ID+ DESIS Lab.

The transition from the industrial age to the age of knowledge brought about diverse changes in the way we live, and the progressive meltdown of the welfare state and globalization have created new problems and, thus, new needs (Beck, 1999; Giddens, 1999; McLaughlin and Davidson, 1985).

The initiatives promoted by groups of citizens and grassroots organizations are a response to everyday problems (like childcare, support of the elderly, healthy food, socialization, amongst others) and to the needs arisen by this new reality, working in a radically different system to the traditional one.

The Web 2.0 phenomenon makes it possible for millions of people to belong to a community, collaborate and share the contents produced in its midst. In virtual communities size is not a problem, in turn it’s an opportunity for ever increasing the wealth of contents and broaden its scope of influence and reach. In fact, one of the decisive factors for P2P networks to work is its size: the bigger they are, the bigger the contents produced and shared, and the bigger their attractiveness to a wider audience. This “mass-innovation”, as Leadbeater (2008) puts it, is the characteristic of the XXI Century: more ideas being shared by more people than ever before, with the help of technology.
When we focus on groups of people that have to collaborate face-to-face, the smaller the better. As they work based in physical peer-to-peer interaction and local collaborative relationships, the bigger they are, the more unmanageable they become as the number of links between people rises much faster than the number of people themselves.

This problem can never be solved, only managed and in modern life the solution has been gathering people together into organizations (Shirky, 2008). But the typical organization is hierarchical with members answering to a manager that, in turn, must answer to a higher manager and so on. This simplifies communication, by avoiding each member having to communicate with everyone else. And to do this, traditional management needs coordination and needs to simplify it; otherwise the costs of directing the members can be higher than the potential gain from directing them. This is why Shirky (2008) refers that certain activities may have some value but not enough to make them worth pursuing in any organized way.

However, the emergence of new social tools is lowering the costs of coordinating group action. In his book, “Here comes everybody” (Shirky, 2008), he argued that we were living in a world where groups of people are coming together to share, work together and take some kind of public action, and that for the first time in history we have the tools that allow it; and that will change society.

Eight years later we can see that Internet of Things are shaping society and helping tackling some social and technical problems all around the world.

**What is Social Innovation?**

Although the Social Innovation topic has been around for 10 years, it has just now reached the political limelight in Europe, be it via EU’s financing policies or via the adoption of social innovation strategies by many governments, especially in countries where the welfare state places a heavy burden on the system.

It is precisely due to a failing welfare state, particularly in Europe, that many citizens have organised themselves to collectively and collaboratively address problems that the Government is unable to tackle (due to an ageing population and declining birth rates, the lack of financial re-sources made more acute by the 2008 crisis, among other factors).

According to Mulgan (2007) innovation becomes an imperative when problems are getting worse, when systems are not working or when institutions reflect past rather than present problems.

As Saint-Simon phrased it, history consists of a succession of social orders and the movement from one order to the next is triggered by the rise of a new class. Different ideas fit different periods of history. The first of the leading peculiarities of the present age is that it is an age of accelerated transition. Mankind has outgrown old institutions and old doctrines, and has not acquired new ones yet. What we are seeing is that society is trying to acquire new ones, and

---

this is possible through the rise of new ways of doing things.

Among several definitions to explain Social Innovation, we can use the one from Mulgan (2007): new ideas that work to meet pressing unmet needs and improve peoples’ lives or the one from DESIS Network²: social innovation can be seen as a process of change emerging from the creative re-combination of existing assets (social capital, historical heritage traditional craftsmanship, accessible advanced technology) and aiming at achieving socially recognized goals in new ways. A kind of innovation driven by social demands rather than by the market and/or autonomous techno-scientific research, and generated more by the actors involved than by specialists. These new ideas have been given birth to new forms of social organization, more innovative and in line with sustainable development and more active civic participation.

Observing contemporary society, cases of social innovation are continuously emerging in the form of new behaviours, new forms of organisation, new ways of living that indicate different and promising developments.

Social entrepreneurs and creative entrepreneurial communities are operating at a micro-level and have the potential to impact on society and profoundly change its character. What they have in common is that they are ordinary people that invent new ways of overcoming everyday problems and of participating in public and social life in an active way. This activity, not so common in a society mostly characterized by passivity, arises from the will to promote change and not to seat back and wait for traditional institutions to solve all everyday problems (Franqueira, 2009).

Social innovations are very important because they advance behavioural changes, without which it is not possible to tackle the problems society as a whole faces. It is possible to find technological alternatives to minimise our carbon-foot print, for instances, but if peoples’ behaviours are not changed, technology will eventually run out of options.

It can be acknowledged that the best way to manage change is not just through implementing new policies on whole populations but through testing and experiment on a small scale, often involving civil society and social entrepreneurs (Mulgan, 2007).

This can be a major opportunity for the intervention of the Design community that is interested in developing innovative sustainable solutions for everyday problems and that wishes to promote, diffuse and eventually replicate those innovative ideas.

**Service Design and Design for Social Innovation**

The difficulty to conciliate social wellbeing, as it is understood today, and sustainability concerns converges more and more towards a consensus on the absolute need to implement new policies and strategies based on sustainable development premises, and design cannot be a bystander in the process.

The approach to environmental subjects has been widely developed in the field of eco-design,

² [http://www.desisnetwork.org/about/](http://www.desisnetwork.org/about/)
aiming to minimise the environmental impact by merely redesigning existing products or designing new ones with recycled or eco-materials. However, trying to solve existing problems based on old methods can hardly lead to the implementation of an alternative successful strategy that can assure a truly new beginning. Instead it leads to the reinstatement of an old strategy, only complemented by a new constraint. What are needed are alternative strategies that imply new ways of knowledge and design thinking models, which are able to promote sustainable solutions for a new scenario building. However, the process to reach this aim is far from being simple and obvious, for it implies changes in the socio-economical models built up along the technical history of the post-modern man.

Considering that design has played an instrumental role in the creation of the current system of consumption, shouldn’t it be promoting its re-invention, departing from more sustainable principles? That re-invention could be done namely through the empowerment of social innovations and the services created at grassroots level, or by the redesign of top-down initiatives that in its original form have failed to deliver the results needed (Franqueira, 2009).

In 1995, Morello (1995) has raised the question of designer’s lack of capability to design services, suggesting that the role of the professional designer should be renewed to embrace the new reality and arguing that that renewal would entail a deep revisitation of design’s conceptions.

Today, social innovation is generating a constellation of small initiatives. Nevertheless, if favourable conditions are created, these small, local social inventions and their working prototypes can spread. They can be scaled-up, consolidated, replicated and integrated with larger programs to generate large-scale sustainable changes. To do that, new strategies able to introduce new ways of thinking in Design are needed, in order to promote sustainable solutions in the formula- tion of possible scenarios. This is one of the statements underlying the Design debate nowadays, and the role of design must be updated to achieve that goal.

Indeed, social innovation processes require visions, strategies and co-design tools to move from ideas to mature solutions and viable programs. That is, they ask for new design capabilities that, as a whole, can be defined as design for social innovation.

The Design for Social Innovation course has the goal of developing new solutions (or improving existing ones) through Service Design and the incorporation of social innovation bases in the collaboration and participation of all the stakeholders. Even though there is a focus in the explo- ration of the analogic component that forms social relationships, it's unavoidable to include the new digital platforms and social media as a tool to activate people.

For those working in this field, there has been a debate about the excessive use of Apps and social media platforms by the students as part of the solution to tackle social problems. The power of social networks, Apps, websites, blogs, etc. can’t be ignored in defining behaviours, in particular in the new generations and in the organization of bottom-up social initiatives. The intensive use of technologies and technological devices however seems to push them away of the main objective of the problems: the absence of face-to-face relations and how to improve people’s lives regarding human relationships.
Social Innovation and the Internet of Things

The link between Service Design and Design for Social Innovation is inextricable of new technologies and of what its integration allows. The democratisation of access to information through digital platforms allows a growing number of people to use different technologies and media to organise activities and perform tasks.

Groups of people and grassroots organizations find in the social networks and digital technologies the means to reach more people to collaborate, not only in the digital space, but, and more important, in the physical space.

People and objects are part of these solutions where the main and common goal is to create social, economical, environmental and cultural benefits. These relations between people and things, where people interact with each other and with things, and things interact with people and between it selves, creates a new meaningful “space” - physical and virtual where it seems everything flows to reach a positive impact in our daily lives.

There are many examples on how new technologies are supporting and helping communities, in western countries or in developing regions. In fact, there are some clusters that benefits from these connections between people, devices, objects and digital and virtual platforms: the health sector, agriculture or education are some of those clusters.

Many elements of the IoT model, such as cheap sensors and wireless technologies, are well suited to conditions in developing countries. Organizations of all kinds are creating and using IoT networks to deliver new solutions that can increase living standards, and they are doing so without the need for large financial investments or the heavy involvement of state bureaucracy (Purdy & Davarzani, 2015).

IoT offers us opportunity to be more efficient in how we do things, saving us time, money and often emissions in the process. It allows companies and governments to re-think how they deliver better services to their citizens.

The European Commission and EU member states are committed to developing strategies to support experiments and the deployment of IoT technologies and services. One of the key strategic goals of Europe regarding the IoT is to promote a human-centred IoT where European values empower citizens rather than machines and corporations.

Involving citizens in the definition of a better, smarter and collaborative city, is key to have a more participatory and more responsible civil society, where each and every one can and should contribute, where grassroots organizations can flourish and where governments and corporations have a responsible and ethical approach to welfare and environmental sustainability.

**ID+ DesisLab and the course of Design for Social Innovation**

Assuming design as an activity of creation - through its interventions, and with social and cultural responsibility, having a strategic role in reducing superfluous consumption in the contemporary society, the course (Design for Social Innovation) now assumes a clear focus on the design of services that promote economic growth through an ethical and responsible approach and an active citizenship through collaboration and co-design practices.

This special focus on the creation of product-service systems allows the bridge between scientific education and the practical extent and points to the need for students to adopt a sensitive approach to the dialogue between design and society, environment and economy. This method aims to provide and develop specific design skills, delivering students essential knowledge about the holistic process of design and the critical analysis of reality, structural to the acquisition of essential knowledge for an innovative design praxis.

This is an approach we develop under the influence of our activity as a DESIS Lab, the only in Portugal and hosted by the Research Institute for Design, Media and Culture [ID+], a multidisciplinary research structure anchored in two institutions: The University of Aveiro (Department of Communication and Art) and the University of Porto (School of Fine Arts). Named ID+ DESIS Lab and a member of the DESIS Network since 2011, this research lab aims to stimulate design-led sustainable social change initiatives, to map creative communities by gathering case studies of social innovation in Portugal and to promote social innovations and sustainability among the Portuguese design community. It was within this context, and perceiving that by 2009 courses of “Design for social innovation” in Design Schools, at undergraduate and graduate levels, were almost inexistent in Portugal — and all over the world — that our teaching in this domain began, in this initial phase under the name “Social Ergonomics of Design”, an optional course of the Master’s Program of Design.

Assuming a role of transition from the well-recognized and established practices, such as product and graphic design, to the emergent reality of service design, the “Social Ergonomics of Design” course allowed us to progressively include the Design for Social Innovation topic on the daily vocabulary of students, colleagues and various stakeholders with whom we established strong collaborations since the beginning of our activity. This condition also promoted an internal de-bate about the relevance of this new fields of the Design activity and their connection with traditional methods of Design teaching.

The progressive formation of the DESIS Network, with examples of DESIS Labs being created in other universities around the world and projects being developed by other former PhD students, provided positive support in order to overcome local difficulties by indicating that the “Design for Social Innovation” was being constituted as an affirmed field in Design theory and practices. It also worked as an example to be showcased at the University of Aveiro.

DESIS Labs are based in Design Schools and design-oriented universities and can be extensions of already existing entities or new ones. This statement was considered in the constitution of the DESIS Lab in the ID+ Institute. The institute was already established as a
research unit in 2011 and included not only social innovation, but also other areas of design theory and practice in its activities. The ID+ DESIS Lab was founded in 2011 as a research group, to operate as part of the +ID Institute. The ID+ DESIS Lab is organized around the following main themes (among others) that are related to social innovation: service design and strategic design for sustainability; education for creativity and innovation; design for the empowerment of local economies and local knowledge.

**Academic Projects**

The last five years showed us that most of the principles previously mentioned were on the foundation of the Design for Social Innovation course, and allowed us to implement new praxis methodologies where students can use, reinterpret and expand most of their traditional design skills acquired during the undergraduate program in Design. The opportunity to work in real contexts and social issues, with people they can interact with, with stakeholders eager to collaborate and seeing results having impact in people’s life, revealed us that this is a highly rewarded process for students, teachers, stakeholders and the community where the projects are developed and implemented.

The following projects are just some examples of how students tackled selected briefs, in what way they settled strategies to enhance communication between communities and how new technologies are essential in the establishment of these practices.

**Title: Conta” (Tell”)**

Students: André Silva, Dirce Russo, Jorge Madeira, Luca Gorgoglione, Sara Rizza

Description: A collaboration project with Museu Marítimo de Ílhavo (Maritime Museum of Ílhavo) regarding the preservation of the collective memories of cod fishermen. Students developed a service where the local community could participate in co-design workshops, based on the storytelling of old fishermen experiences and supported by a network of local institutions, such as schools of Art and Design, schools of Tourism and Hospitality and schools of Performative Arts. The outcomes of the workshops, might result in gastronomic experiences, exhibitions or performances, among others, could then be enjoyed by the museum's visitors.

---

Figure 1 – Conta”: Service description, workshop cards, merchandising
Figure 2 - Conta": facebook page and website (homepage, project description, workshop description, calendar)
Title: Pé na Ria

Students: Andrea Taverna, Hélder Azevedo, Marta Gonçalves

Description: A tourism service where the heritage, cultural and natural resources of the “Ria” de Aveiro lagoon were enhanced through the connection of memories, knowledge and traditions from the local community, particularly the fishing activity, and the fishermen themselves. Its main objective was to provide a bigger link between the visitor and the city by proposing a new touristic experience with the guidance of retired professional of several activities associated with the “Ria” de Aveiro lagoon.

Managed through a web platform that allowed the customization of the service, tourists could engage in fishing activities, salt harvesting and gastronomical practices supported by a network of stakeholders that ensured the success of the service.

Figure 3 - Pé na Ria: Service description, support equipment.
Title: Avós e Nós (Grandparents and us/knots)

Students: Joana Silva, Joana Carvalho, Mónica Carvalho, Tiago Gomes
Description: With the constant average life expectancy increase searching for better practices and solutions that promote wellbeing for elderly people became one of the main issues in modern societies. Raising awareness to ageing among younger generations was at the core of this service where the challenge stood in achieving intergenerational relations on a “win-win” perspective, simultaneously improving the actual living conditions of elderly and allowing youngers to out-look their own future. The final solution proposed consisted of a web platform — where register members could offer or request specific services — and a “loyalty card” where members might save the total or part of the income from the services provided. This “plafond” could later be used on amenities from nursing homes or health care institutions.
Figure 5 - Avós e Nós: Service description

Grandfather John is looking for a service / offers a service

The online platform brings them together and the service happens

The money from the service is stored on the loyalty card and can be used in the partner companies that later return part to the nursing homes in the form of goods.

Everyone is happy!
Title: Cãovida

Course edition: 2013/2014
Students: João Merendeiro, João Jacinto, Carlos Eduardo Pereira, Joana Pires, Cristina Fer- nandes, José Nogueira
Description: Consisting in the redesign of a pre-existing service, the “Cãovida” project was initially developed with the objective of promoting good health habits in kids by walking a dog.
Aimed at younger generations with obesity problems the original service consisted in a kit with a manual, a pedometer, a leash and a scarf.
Identifying several problems, such as the obligation of having a dog, the lack of tracking of the proposed activities and motivational issues, students proposed a “game based” solution where
all the tracking activity were registered through an app with diverse community challenges, where members could compete among themselves. Besides that, dog kennels were included as stakeholders where members could borrow a dog if they don’t have their own.

Figure 7 - Câovida: Service description, advertising, kit box.
Conclusions

Latest advances in technology, that brought us less expensive ways of mass communication, low-cost hardware, crowdsourcing and internet of things, also provided new ways of (re)envisioning services and public services with the potential to have a strong social impact in such different fields as healthcare, environmental sustainability, education, transport, political representation, housing among others. To empower citizens in new ways that, until now, were only accessible to a small minority, with this tools, stimulates dipper level of involvement on their communities and allows them to engage in innovative practices of civic action.

The academic projects presented showed us a diversity of circumstances where distinctive technologies were used to support social actions, either as a back-office infrastructure — when they provide a structure for the service to develop — or as tangible interactive tool that encourages
new habits and practices — as showed on the “Cãovida” where the gamification project was the actual response to one specific social need.

Nowadays it is almost impossible to design a service without using social technologies as an important add-on. All the cases we showed take advantage of some of the most usual tools available for everyone. Digital social networks platforms are currently an important and immediate way of reaching people, as we could see on the “Conta” and “Pé na Ria” examples; dynamic websites are fundamental systems of assuring the flow and speed of communication between providers and users of a service, as presented in the “Avós e Nós” case; and mobile devices — with all the new capabilities that today thousands of individuals have at their disposal in their pocket — also offer new functions like geo tracking, step monitoring and real-time exchange of information, among others, like in the “Cãovida” example.

This is a “brave new world” where technologies learn from humans but also humans have a lot to learn from technologies. Teaching someone to be a twenty first century designer is a task that cannot ignore this reality. In this way, training a designer to develop meaningful social services requires a border interpretation of the notion of social realm, not limited to the social relations between individuals but also between individuals and…things.

Teresa is a designer and holds a PhD in Design (Politecnico di Milano). She has been lecturing at the University of Aveiro since 2001 and is a senior researcher at the ID+ Research Centre, coordinator of the ID+ DESIS Lab, a member DESIS Network – Design for Social Innovation and Sustainability. Teresa is also Member of the DESIS International Coordination Committee and coordinator of the Design Factory Aveiro. She is an invited lecture at Politecnico di Milano for he Social Innovation and at the College of Design and Innovation, Tongji University for the Design for social Innovation & Sustainability.

She is the local coordinator of three European projects: Strategy for Change Erasmus + Strategic Partnerships. Her research interests focus on themes related to service design and social innovations, and alternative scenarios towards more sustainable economic and social models and she has been invited as a keynote speaker and to take part in several workshops, particularly in relation to scenario building for social innovation services and the identification of possible solutions to be used for specific projects in creative places. Teresa is the responsible for the Design for Social Innovation subject in the Design Master Degree.

**Gonçalo Gomes**  
Gonçalo is an assistant professor at Universidade de Aveiro, since 2007, where he is responsible for the Projecto em Design Básico (Basic Design Project) and Projecto em Design I (Design Project I) subjects. He is also, since is foundation, researcher for the Research Institute for Design, Media and Culture [ID+] where he develops studies in the field of Participatory Design for the Future Cultural Heritage and, since 2012, he is also Operations Manager of the ID+ DESIS Lab, a member of the international DESIS Network – Design for Social Innovation and Sustainability. He also teaches the Design for Social Innovation subject at the Design Master Degree
New Challenges when Teaching UX Students to Sketch and Prototype

Joep Frens, Eindhoven University of Technology, ID, DQI group, j.w.frens@tue.nl

Jodi Forlizzi, Carnegie Mellon University, HCII, forlizzi@cs.cmu.edu

John Zimmerman, Carnegie Mellon University, HCII, johnz@cs.cmu.edu

Abstract

In this paper we report on new challenges when teaching UX students how to sketch and prototype their designs. We argue that UX students sketch and prototype differently than other design students, and we discuss how changes in the field necessitate a response in education. We describe sketching and prototyping as a continuum that students successfully traverse when they follow a process of ‘double loop learning’. We highlight three new challenges: (1) New computational design materials, (2) new maker tools, and (3) changes within the tech industry. We explore these three challenges through examples from our students, and we outline strategies for sketching and prototyping in this new reality. We conclude that this is a starting point for further work on keeping education up to speed with practice.

Keywords: sketching, prototyping, UX design, double loop learning

Introduction

Teaching interaction design/user experience design (UX) students how to sketch and prototype their ideas has always been a challenge. UX is different than most other design practices because designers give form to behavior: the behavior of the products, services and systems. UX designers might create a conversational UI, a mobile app, or an Internet of Things device. While they can use traditional sketching and prototyping methods to address the physical form or the visual elements, envisioning and refining behavior remains challenging. Students learning architecture, communication design, or industrial design typically spend time in their studios sketching with pencil on paper and prototyping with physical materials to better understand what the form of a thing might be. UX students work differently. They spend time making and arranging sticky notes, sketching with narrative to explore possible scenarios of use, and drawing and scripting storyboards that often function as early prototypes.

Over the last several years, advances in the tools professional UX designers use, advances in the technical materials, and changes to the IT industry have all made teaching UX students how to sketch and prototype even more challenging. Advances offered by new maker tools move design students farther from the tacit knowledge gained from working materials by
Technical advances in the areas of big data, machine learning, and crowd-power present UX designers with an ever-growing array of possibility, but also with a huge gap in understanding the capabilities of these emerging design materials. The shift within the tech industry away from products and towards services challenges students to envision financial models as a part of their sketching and prototyping. It changes the challenge from making things users want to searching for co-production of value between users, customers, stakeholders, and service providers. Finally, the growing practice of A/B testing means many tech companies now focus on deploying minimally viable systems that get tweaked towards optimal design following deployment, and not during a design process that precedes release.

In wrestling with this growing set of challenges, we have developed several insights that can aid others in teaching their UX students how to sketch and prototype their ideas. These insights frame the continuum between sketching and prototyping as a process of double loop learning. We hope the insights will help UX instructors to better critique student work and that they will result in expert UX students who easily transition into industry practice. Our insights include developing tacit knowledge of new maker tools, collaborating on teams with technology experts, creating conceptual models as prototypes, and teaching students to prototype toward their greatest risk (i.e., that what is most likely to fail) instead of prototyping based on fidelity.

**Background on Sketching and Prototyping**

Today, many design instructors hold a traditional and possibly even romantic view of how to teach sketching and prototyping. They often teach students to sketch by roughly drawing many possible forms by hand as a way of exploring the solution space. Students next produce higher fidelity renderings on their way to producing high-fidelity 3D models of their idea, such as a clay model for a new car. Throughout this process, students engage in both individual and social classroom critiques where their ideas are challenged and sometimes celebrated. The design actions and the discussion collectively carry students from sketching to prototyping to arriving at their final design.

Many design researchers have discussed sketching and prototyping. We do not attempt to provide a detailed review, as this would exceed the bounds of a conference paper. Instead, we touch on a few key insights and advances on sketching and prototyping as they relate to and distinguish UX design.

Much of the design research discussing sketching and prototyping focuses on architecture and industrial design. Most of it draws on Schön’s discussion of design as a reflective practice involving reflection *in action* and *on action* (Schön, 1984). When involved in the act of sketching, designers *reflect in action*. They react to each mark they make, revealing what their idea is to themselves as they proceed. Once they have produced a sketch or several sketches, designers *reflect on action*; they assess what the idea is and decide to build on it or to explore in a new direction. Schön later described this as the designer having a conversation with material, where the way the material talks back to the designer plays an important role in how the conversation unfolds (Schön and Bennett, 1996). UX researchers have noted that sketching with software is challenging as it is an immaterial material, and it
makes this conversation difficult (Ozenc et al., 2010).

Design research has helped advance understanding of sketching and prototyping by more closely focusing on the final product or outcome (Buchanan, 1992). Buchanan’s work categorized design as producing four types of output: symbolic and visual communication, material objects, activities and organized services, and complex systems or environments. He describes these as areas of invention, not as design practices. Design practices work across these areas. For example, a UX design that helps shoppers check themselves out of a store would involve communicative artifacts to orient the user to their choices, material form of the device(s) used, and the activity of shopping. The design would both situate the activity within the current context of a store while also attempting to transform this environment by removing cash registers and checkout stations. Buchanan’s work illustrates that sketching and prototyping go well beyond the physical form of an artifact.

Since the development and rapid adoption of digital design tools, such as CAD systems, design researchers have more openly questioned the need for sketching in the form of freehand drawing on paper. These types of sketches are performed to help designers develop and reflect on their ideas. One study showed that expert architects could produce high quality designs regardless of whether or not they engaged in an explicit sketching process (Bilda et al., 2006). Instead of sketching, participants developed designs thinking out loud, while blindfolded. However, the architects were not happy with this process. Research looking across several design practices showed that the conversations designers engaged in seemed to have more impact on advancing design ideas than freehanded visualizations (Jonson, 2005). What remains less clear his how sketching leads to artifacts that support these critical conversations. While there is more nuance to these studies than we have space to explain, they point to the possibility that the primacy of sketching as drawing needs to be re-evaluated. Interestingly, design education has remained deeply committed to drawing alone as core to how we teach students to sketch.

Buxton’s work has been seminal in helping to advance the understanding of sketching and prototyping done in UX (Buxton, 2010). Prior to this work, both design practitioners and instructors often used these terms somewhat interchangeably. For example, they would describe things like a scenario, storyboard, or a wireframe as a sketch or as a prototype. Buxton described sketching and prototyping more as a continuum. Designers were sketching when they worked on getting the “right design” and they were prototyping when they worked to make the “design right.” As designs became prototypes, the act of sketching worked on ever more granular elements. For example, designers sketch to discover they should be making a food-sharing app. Then, when wireframing the app, designers sketch to develop ideas of how to navigate through the app. Buxton noted that in UX, designers had many tools that supported digital prototyping, but they had almost no tools for sketching.

Participatory design emerged as a practice to develop IT systems for the workplace. In order to address the disruptive change of placing computers in work environments, researchers in Scandinavia created teams with workers who had domain expertise in the work and with developers who had expertise on what computers could do (Muller and Kuhn, 1993). Collectively, the team prototyped future ways for people to work together in order to reveal where computing could add value (Ehn and Kyng, 1991). They prototyped the social to discover the thing.
As computing became less about work and more about other aspects of people’s lives, designers created new sketching methods like bodystorming that draw on the designer’s understanding of their own body as a way to engage with embodiment, perceptual motor skills, and the social performance of interacting with things (Buchenau and Suri, 2000). As part of this effort, designers also created experience prototyping and prototyping for social action, with a focus on investigating the felt-life experience of a potential product or service before it gets developed (Buchenau and Suri, 2000; Kurvinen et al, 2008).

Other approaches explored abstraction in the form of models to advance sketching and prototyping. For example, the analysis-synthesis bridge pushed sketching and prototyping in a different direction — away from felt life experience and towards abstraction (Dubberly et al., 2008). This model divides the UX design process into four quadrants: what “is”, the model of what “is”, the model of what “could be”, and what “could be” (Figure 1). UX designers transition from researching to making by sketching and assessing models of the future they want to bring into being. Once they have agreed upon the future they want, designers ideate and iteratively refine new product or service offerings. The reflection they engage in is on both the thing and the future it intends to bring into the world.

Collectively, this research shows that UX designers sketch to discover the future they want and to discover products or services that can help them achieve this desired future. This might be done in isolation, following a user-centered design process, or it might be done as co-design/participatory design; in collaboration with users and other stakeholders.
Designers investigate communication, product forms, activities and behaviors, and the larger systems these things reside within. As the work proceeds from sketching to prototyping, the focus shifts to more assessment of whether the design achieves the desired future as opposed to the search for a desired future. Conceptual models can also be used to represent the future, scenarios of use, system behaviors, environments, and stakeholders affected by the design process. As the work proceeds to prototyping, UX designers develop storyboards, wireframes, interaction flows, more detailed conceptual models, high fidelity visuals, and semi-functioning systems. These things remain difficult to sketch and prototype because of a lack of tools particularly for sketching UX and because software, one of the main materials used in interaction design, remains difficult for designers to have a conversation with.

One of the defining characteristics of sketching is how its process reveals both potential solutions and potential pitfalls. Sketching is a non-linear process where the solution space is explored along with the assumptions and convictions embedded in the design brief and in the designer (Dorst and Cross, 2001). This process of framing and reframing, driven by the ambiguity (or indeterminacy) of the sketch (Fish and Scrivener, 1990), is characterized well in the concept of ‘double loop learning’ (Argyris, 1976). With double loop learning, both the underlying rules as well as the consequences of a decision matter (Argyris and Schon, 1974). As designers sketch and then prototype, the advances they make change their underlying values and assumptions as these relate to both the thing and the impact the designer intends the thing to make on the world (Figure 2). We see this notion of double loop learning as much more at the center of design than the idea of sketches as drawings made by hand.

**New Challenges for UX Sketching and Prototyping**

When teaching how to sketch and prototype across the UX design space, instructors
typically ask design students to brainstorm, bodystorm, and create many scenarios of use that investigate different users, situations, contexts, and user needs. Much ideation happens using narrative, as this is a design material that lends itself to giving form to the behavior of systems in dialogue with the potential actions users might take. Students are often inspired by conducting some type of research prior to sketching, working from a design brief, or working from a set of personas. Increasingly, UX design programs also have students investigate the possibilities of digital technologies using platforms like the Arduino microcontroller or visually-focused software like Processing. Students “play” with these digital materials in the same way traditional design students play with cardboard in the studio to gain a tacit understanding for the capabilities of digital materials. Currently, these materials lend themselves much more to prototyping, making the thing a designer has in mind, than to sketching, trying to discover the thing to make.

Students transition from sketching to prototyping their ideas by working with a variety of tools. Many generate storyboards by hand before creating wireframes and interaction flows. Students also often make videos showing simulations of what a system might be like, especially when it is meant to communicate ideas design students cannot easily create themselves, such as systems embedded in environments, Internet of Things designs, interactions with robots, or conversational interfaces. In some cases, design students create more fully realized prototypes using web development tools, sensors and microcontrollers, or even mobile development tools. Sketching and prototyping works best when UX students develop a deep, tacit understanding of the capabilities of the technologies they hope to employ in their designs.

Over the last several years, advances in tools, design materials, and in the IT industry have only increased the challenge of teaching UX students to sketch and prototype. Through a process of discussion with alumni working in industry, discussions amongst ourselves, collaborative writing, and reflection on our own teaching, we identified several changes and advances to UX that complicate teaching students to sketch and prototype:

1. New computational design materials: big data, machine learning, and crowds
2. New maker tools: laser cutters, 3D printers, CNC machines
3. Changes to the tech industry: transition from products to services, lean startups, and the rise of A/B testing

Computational Design Materials

New computational design materials, specifically big data, machine learning, and the many technologies that leverage crowds as a resource complicate UX sketching and prototyping. When trying to innovate existing services, UX designers often find themselves confronting huge datasets of user behavior, and they are increasingly expected to help discover creative new ways to construct value with the data while protecting privacy and working in an ethical way. Banks have mountains of transactional data; healthcare systems have stores of patient and care data; government and social agencies have increasing access to historic sensor data such as weather and user data.
Visualization and data mining are typical ways engineers learn to investigate datasets. However, design students typically do no work with these tools and these tools have not been developed to support the ways designers search for possibilities.

One increasing way technologists have been constructing value from data is through the use of machine learning, which can detect frequent patterns, find more optimal paths and strategies, or discover insights and relationships. This material can be challenging for UX designers because it employs statistical intelligence, which is far from human intelligence and generally lacks common sense. Machine learning systems often require ongoing collection of labels so they can continue to learn, creating new interaction requirements. These systems also make inference errors that can be difficult to predict before completely building a system and testing its performance.

The recent emergence of crowd computing offers UX designers a very different kind of intelligence they can apply to their designs. The development of large-scale social computing systems has created both free and paid labor forces that do things previously unavailable through computation. For example, Youtube users collectively discover and extract key content from video and social mechanisms. Counting views allows crowds to collectively curate the quality of digital video clips. Services like Amazon’s Mechanical Turk allow developers to rapidly engage people in completing micro tasks. One of our favorite examples is the VizWiz system, which allows blind users to take a picture and get near real-time textual descriptions. VizWiz users have asked the crowd to read thermostats, to read cooking instructions from food packages, and even to describe attractiveness of the people they are with (Brady et al., 2013).

When sketching, UX design students often fail to consider the capabilities of these new materials. As they transition from user research to sketching, students search for opportunities for technology to add value, but this search is always limited by their understanding of what can be done. On the occasions that students do begin to consider big data, machine learning, and crowds, they often think of these materials as if they are magic that can do anything. Their lack of a tacit knowledge of these materials makes it difficult for them to envision new futures. As they move their ideas forward, and transition from sketching to prototyping, they almost always lack the technical expertise or access to resources such as a paid crowd or a large dataset that they might leverage to investigate more fully what might and might not be possible and what might and might not be a preferred future.

Maker Tools

The emergence of tangible interaction (Hornecker and Buur, 2006) — the use of material artifacts to control and interact with digital systems — as well as the increasing technology focus on the Internet of Things (Hounshell, 2017) has helped to promote the importance of designing material artifacts as a core part of UX design. While UX design educators have grown more interested in teaching students to investigate the material forms of products along with their behaviors and their sensing services, the 3D form giving aspect has become complicated due the emergence of maker tools, e.g., 3D printers, laser cutters, and CNC machines. These new tools typically take input from a digital file and then add or remove material in the process of making a physical thing.
Industrial design students often learn to work with materials by hand before moving to digital tools. They typically carry out several design projects where they cut cardboard or other materials by hand in order to learn its capabilities as they repeatedly cut, fold, bend, and glue. Students then move to more dangerous tools like table saws and band saws. They learn the capabilities of wood and plastic by cutting and feeling the resistance, by sanding and fitting pieces together, and by finishing with paint and stains.

Maker tools place a computer as a mediator between the designer and the target material. They remove the ability to gain a felt understanding and tacit knowledge as the tool does all the adding or removal (Frens and Hengeveld, 2013). This is particularly problematic when looking at this practice from the perspective of double loop learning. The ambiguity that fuels the conversation with the material is simply not present. Maker tools produce ‘perfect’ results that hamper the process of reflection on the assumptions and beliefs embedded in the design brief and brought to the table by the designer. In this process of creation, all sensory feedback is removed, creating a gulf between the design student and the material, and preventing an effective conversation with the material from starting. They create a separation between planning (making the digital file) and acting. The process of making that affords unforeseen routes to unimagined solutions is not accessible.

Changes in Tech Industry

Over the last decade the tech industry has almost entirely transitioned to a financial model oriented around multi-stakeholder services rather than one product designed for one person. In the past, UX designers made things people wanted to purchase. Now, increasingly, UX designers find themselves working on projects where the users and customers are two different groups (for example, Google search users and advertisers) or where systems bring disparate groups of people together (for example, ride sharing drivers and riders). In both cases, the purpose of the design activity is to envision an ecology where value flows across several interrelated stakeholders. While UX designers know how to prototype interaction flows and screen designs, it is less clear how to teach students to sketch and prototype an effective ecology of exchange. When working in these spaces, teams often spend as much time prototyping financial models as they do interaction designs.

Another change in the industry has been a move by many startups to a “lean” model of development — the idea of making a minimally viable product as a first item to deploy. This mindset can conflict with the focus on UX on discovering and expanding upon what users want and desire. When working in this climate, UX designers must work to discover the minimal that can be delivered in order to drive an initial round of product/service adoption.

When systems get deployed, tech companies increasingly use A/B testing as a way of modifying and redesigning their systems. When doing this, companies make several versions of the same thing and assess which one produces the user behavior they most desire. This is different than a traditional model of design, where the designer is in charge of creating and evaluating renditions of a product. In fact, one designer famously quit their job at Google due to the dominant culture of testing every design decision (Walker, 2009).

A/B testing challenges the social critique model that has been long held in design, turning it from a discussion into a search for empirical evidence that one idea is “better” than another.
A/B testing, similarly to lean UX, breaks a design down into many small pieces that can be individually tested and measured, and it often misses changes things holistically, as there is little opportunity to do so. A/B testing changes the power dynamic in the decisions around what to make and when a designer’s judgment should be trusted. Traditional studio courses, with their dependency on the critique do not prepare students for this new reality they will increasingly face.

Insights on Teaching the Future UX Designer

To address these challenges, we spoke to our many alum working in industry about their practices. In addition, we reflected on our work with constructive design research (Zimmerman and Forlizzi, 2014) where we design new artifacts as part of academic research. Our research includes tangible computing, Internet of Things, digital service design, human-robot interaction designs, interaction with intelligent systems, smart environments, and interaction with social/mobile systems. We subsequently distilled a small set of insights that begin to address the challenges we outlined above. These insights serve as a first offering in space that requires considerable more design research.

New Technical Design Materials

We have two recommendations that help sensitize UX design students to working with unfamiliar technical materials. Both help students understand the capabilities of the material so they can better recognize the opportunities to play with it in a way that increases the likelihood of envisioning things that can be built. First, we recommend that students conduct a competitive analysis of current systems. For example, if students are to better understand the possibilities presented by conversational user interfaces, ask them to perform a competitive analysis of current systems. As part of this work, students should generate design patterns to reveal the different ways other UX designers have integrated this technology into their designs. Patterns should reveal matches between the user’s intention, the context, and the abilities of the technology. Based on the resulting set of design patterns, students should abstract a set of technical capabilities. This may require them to examine some of the research literature on the underlying technology, as the capabilities should address both the abilities and the current limitations of the design material.

Second, we recommend placing students on interdisciplinary teams. When working on big data or machine learning, try to add someone with expertise in data science. When working on crowd-powered systems, try to add an expert in social computing. Ideally, the interdisciplinary team will work together in both the early, middle, and late stages of the design process. Adding an expert helps to place a person as a proxy for the new material. As student teams work to identify opportunities, ideate possibilities, and refine their ideas, the more design-focused students can engage team members with technology domain expertise into a Schön-like conversation with the technical material (Schön and Bennett, 1996).

These two activities singly or in combination will not result in a UX design student who is an expert on the new design material. However, it will result in a student who is sensitized
to the challenges of working with this material and who is better able to discover opportunities to apply it.

New Maker Tools

In addressing this challenge, we have had to work on our old-timer designer bias that doing early design work by hand is better than doing this work on the computer. The best evidence we found that challenges this bias is in our own students who have somehow gained a strong felt-understanding for maker tools, and can produce highly inventive designs even though they start in the digital space.

One example that was particularly insightful comes from a first year master’s student who is skilled and experienced with new maker tools and blended this skill and experience fashion aesthetics. The student worked on a service design for an exclusive car brand, positioning his work in the near future where ownership of cars might be more exclusive than it is now. He speculated that his target users would want to show off their ownership of an expensive car by showing the key fob, such as casually laying them on the bar while drinking espresso. He envisioned a parametrically customized and fitted bracelet that would act as key fob and bragging apparel. Here we focus on his design process rather than on the service itself.

The student tried to answer the question of how a computer algorithm for generating forms could be tuned to embody the form language of an exclusive car brand. After a few, very literal tries with 3D printing exact representations of brand elements, his exploration moved to Processing, where he used elements of the car to seed a generative algorithm. Tuning and tweaking algorithms, he found that the abstraction of Processing did not give him enough ‘control’ over the expression of the brand language. Next he took off the shelf, scriptable animation software (cinema 4D) and ‘misused’ it to run generative scripts that would give him algorithmically driven progression of form expression over time. This gave him the iterative tool that he needed to tune his algorithms and he engaged in a process of 3D printing families of bracelets that matched the brand language (Figure 3).
The student created his own tools in order to explore his design challenge in a way that it opened the conversation with the digital material (Stienstra et al, 2015). He could do this because of his extensive experience and deep understanding of both algorithmic form generation and 3D printing.

Students who can design effectively using maker tools spend a tremendous amount of time working with one or two individual machines. In the same way many of us learned about materials by playing with them in the studio, these students have gained a tacit understanding of what the tool can do by spending lots of time working with different materials. We notice they often have a systematic approach of trying many small changes in both settings and in the details of their digital files. They employ a rapid process of iterative exploration, tweaking things until they discover a combination that works. Gaining a tacit knowledge of the tool helps these students to both sketch with the tool and to iteratively refine their designs.

New Technology Development Practices

To help students better understand how to sketch and prototype for services, instructors should first provide grounding on the differences between products and services and background on key service concepts such as co-production of value (Prahalad and Ramaswamy, 2004), customer competence (Prahalad and Ramaswamy, 2000), and service concepts (Goldstein, 2002). When ideating, students should focus on discovering opportunities for value co-production — situations where all of the stakeholders will benefit. Students should also take advantage of customer competence by asking not just what the service provider can do for users, but also what users can do that benefits the service provider. Often the best exchanges of value are not about money. For example, designs that use gamification operationalize this idea, often trading the entertainment of a game to get users to do work for free. Finally, students need to understand that the outcome of a service design project is a strategy that describes how both customers and the service provider get what they want. Once a service concept has been developed, then many independent design projects can happen somewhat independently, as they all follow the same underlying strategy.

When prototyping services, students should learn to explore and investigate ideas by sketching conceptual models of possible future states. They need to reveal the underlying system of value flow between stakeholders before they attempt to design other artifacts within a service system. As designs advance, we recommend prototyping by simulating the service encounters (Frens et al., 2012). These can be quickly created and assessed using UX design methods like experience prototyping (Buchenau and Suri, 2000).

To prepare students for working in a world of lean startups and minimally viable products, we recommend changing the focus of prototyping. Instead of focusing on advancing through levels of ever-higher fidelity, students should focus on risk. They should examine their design idea and determine the most likely reason it might fail. They should then focus their
prototype on assessing if this specific challenge can be overcome. If not, then they should pivot to a new idea, again evoking double loop learning. This focus on risk prevents teams from working on an idea that will never work. In one example from our teaching, we had a UX team that wanted to make an automated translation app for people that travel. The first risk they encountered was the cost of data services when traveling internationally. This killed the idea, but helped the team to pivot and focus on renting Mi-Fi’s at airports so international travelers could have cheap access to data services.

To prepare students for a tech industry that may seem hostile to design judgment that is not backed up by empirical evidence, we recommend bringing some of the culture of A/B testing into studio sketching and prototyping activities. Instead of relying solely on the critique as an evaluation of ideas, instructors can encourage students to leverage the crowd as a design resource. For example, when students generate a set of possible ideas, they could post these as a set of choices to relevant communities using services like Reddit. For a more rigorous approach, students can quickly create online survey services and conduct a pairwise comparison of ideas. Asking participants to share their rationale provides some insights on why their designs are being rated in a certain way.

We do not intend or want to replace the studio critique with crowd opinions. Instead, we have found that collecting this information before a critique can bring a new and valuable dimension to the conversation. We also feel that practicing how to discuss design judgment in conjunction with empirical data helps prepare students to describe their intentions in a way that leverage the data instead of trying to deny it.

Conclusion

The pace of change with respect to UX tools, technology, and work practices have only increased the challenge of preparing UX students to enter industry. Over the last several years, we have observed that the standard methods for UX sketching and prototyping no longer fit with many of these advances and changes. In this paper, we share a set of insights gathered from discussions with our alum working in industry, informed by our own constructive design research projects, and based on changes we have made to our own UX studio classes. We view these insights as a starting place in a much-needed conversation with both UX practitioners and UX instructors. There is a huge need in our community to try new sketching and prototyping approaches in both education and practice, and to reflect and share what does and does not work. Through the collective actions of researchers, educators, and practitioners, we can continue to prepare students to enter UX practice ready to help and advance the state of UX design.

Author Biography

Joep Frens

Joep Frens was born on September 11th, 1974 in Amersfoort, the Netherlands. After obtaining his master degree in Industrial Design Engineering from Delft University of Technology he went to Switzerland to pursue a career in research at the Swiss Federal Institute of Technology in Zürich. He returned to the Netherlands as a PhD student. In 2006 he received his doctoral diploma from the Eindhoven University of Technology and started as assistant professor at the same university. He held the prestigious, invited position of 2014-2015 Nierenberg Chair of Design at the Carnegie Mellon University School of Design. He teaches courses on all academic levels and advises a number of PhD students. He regularly gives workshops on cardboard modeling and runs a website around the technique.

Jodi Forlizzi

Jodi Forlizzi is a Professor of Human-Computer Interaction in the School of Computer Science at Carnegie Mellon University and a Co-founder of Pratter.us, a healthcare startup. She designs and researches systems ranging from peripheral displays to social and assistive robots. Her current research interests include designing educational games that are engaging and effective, designing services that adapt to people’s needs, and designing for healthcare. Jodi is a member of the ACM CHI Academy and has been honored by the Walter Reed Army Medical Center for excellence in HRI design research. Jodi has consulted with Disney and General Motors to create innovative product-service systems.

John Zimmerman

John Zimmerman is a Professor of Human-Computer Interaction in the School of Computer Science at Carnegie Mellon University. He teaches courses on interaction design, service design, HCI, and innovation. His research investigates four areas: (i) interaction with intelligent systems, (ii) service innovation, (iii) crossing the digital-physical divide, and (iv) research through design as a scholarly approach to inquiry.
The Research on Design Framework for Citizen Science

Zhiyong Fu¹, Tsinghua University, Beijing, China, fuzhiyong@tsinghua.edu.cn

Lu Wang³, Beijing Normal University, Beijing, China, lu.wang@mail.bnu.edu.cn

Abstract

Citizen science is a process in which ordinary citizens contribute to scientific research. How to create citizen science design framework to achieve better awareness, initiative and action is our research focus. This paper will explore citizen science design in the context of smart city, on the basis of activity theory and by means of digital social innovation. “Smart City” concept provides new elements including social communication, collaborative design and innovative community to citizen science. With the rapid development of science and information & communication technologies (ICTs) and with the arrival of Web 2.0, social innovation is endowed with digital factors so as to be evolved to digital social innovation (DSI) which gives various design perspectives on citizen science and also plays an important part in establishing citizen science evaluation model. In this paper, a citizen science design framework consisting of citizen science content model, design model and evaluation model is proposed by discussing related theories, models and citizen science cases. It acts as not only design lead to inspire two citizen science case practices, but also an evaluation term in the view of citizen science. The framework and models developed in this research will hopefully be leveraged and refined to support citizen science design in the future.

Keywords: citizen science; smart city; activity theory; digital social innovation

Introduction

Smart City Background

Smart city is envisioned as a kind of wired and ICT-driven cities that provide better urban life [1], innovative services [2], new business opportunities [3], efficient governance and sustainable environment development [4]. More and more cities are beginning to consider civic participation, and regard the smart citizen as a new direction of smart city. A smart sustainable city is an innovative city that uses information and communication technologies (ICTs) and other means to improve quality of life, efficiency of urban operation and services, and competitiveness, while ensuring that it meets the needs of present and future generations with respect to economic, social and environmental aspects” [5]. It is called technology-intensive city in which sensors spread and technology plays an indispensable part and it is one of the directions of smart city. While the other direction of smart city focuses on smart citizens. The common characteristic is embarking from the reality of the community needs, using the new techniques of digital tools, through participatory design so that the public participate in the maintenance of the new community building activities [6]. So smart city is characterized by comprehensive perception, ubiquitous connectivity, pervasive intelligence, and people-centered sustainable innovation which are featured by
user innovation, mass innovation, open innovation, and collaborative innovation [7]. Smart citizens, comprehensive perception, ubiquitous connectivity, pervasive intelligence, people-centered sustainable innovation are in some degree related to developmental features of citizen science. Consequently, smart city is regarded as the context where citizen science is formed, developed, advocated and popularized.

Tech Background

In the era of information, modern information and communication technology (ICT) plays a significant part in citizen science emergence and development. According to O’Reilly [8], “Web 2.0 is the business revolution in the computer industry caused by the move to the Internet as platform, and an attempt to understand the rules for success on that new platform. Chief among those rules is this: build applications that harness network effects to get more people to use them”. In the background of Web2.0, new technologies such as the Internet, big data, cloud computing, wearable devices, intelligent home, artificial intelligence and SNS (Social Networking Services) have been applied to citizen science design.

Citizen Science Background

Citizen science is derived from open science which is the first scientific movement fueled by social network revolution. Over the last 5-10 years, citizen science has become increasingly popular. New digital tools make crowdsourcing more popular and a range of digital devices and sensors enable volunteers to collect, submit, and verify data. Following [9], the definition of citizen science is the form of collaboration involving active engagement of members of the public in scientific projects which address real world problems. There are different types of citizen science involving different levels of skill and commitment. Citizen scientists may participate in all aspects of the scientific method, from problem formation, to data collection, to analysis, and dissemination of the research results [10]. Leveraging well designed, accessible social media, crowdsourcing, cloud computing, remote sensing, visualization and gamification technologies hold great promise for citizen science.

Related Research

Related Theories

Among theories, the most important theory referred in this paper is activity theory. Activity theory (AT) is more of a descriptive meta-theory or framework than a predictive theory. It considers an entire work/activity system (including teams, organizations, etc.) beyond just one actor or user. It accounts for environment, history of the person, culture, role of the artifact, motivations, and complexity of real life activity. One of the strengths of AT is that it bridges the gap between the individual subject and the social reality—it studies both through the mediating activity. The unit of analysis in AT is the concept of object-oriented, collective and culturally mediated human activity, or activity system. This system includes the object (or objective), subject, mediating artifacts (signs and tools), rules, community and division of labor [11]. A particular activity is a goal-directed or purposeful interaction of a subject with an object through the use of tools, which indicates that citizen science can be thought as a purposeful interaction of a citizen subject with an science object through the
use of technology tools. AT recognizes the internalization and externalization of cognitive processes involved in the use of tools, as well as the transformation or development that results from the interaction [12]. So does citizen science.

Social Innovation and Digital Social Innovation

Social innovation has gained acceptance and popularity in both economic and social areas now. The current Stanford definition of social innovation describes that, “a social innovation can be a product, production process, or technology (much like innovation in general), but it can also be a principle, an idea, a piece of legislation, a social movement, an intervention, or some combination of them” [13]. Robin Murray, Julie Caulier-Grice and Geoff Mulgan from the Young Foundation defined six stages of social innovation and they are prompts, inspirations and diagnoses, proposals and ideas, prototyping and pilots, sustaining, scaling and diffusion, and systemic change [14].

Originated from social innovation, digital social innovation is one kind of social innovation whose objective is to help raise different solutions to the same problems in digital ways. Six areas are presented in NESTA’s report and they are open democracy, open access, collaborative economy, awareness network, new ways of making and funding acceleration and incubation [15].

Design and Development of Citizen Science

Citizen science has a research history and a great many application areas. Along with the historical process, amateurs are involved in scientific research process with different participation degrees. In 1874, a project was launched to measure the transit of the planet Venus and its personnel gathered and collected data from multiple positions on the globe simultaneously [16] and this project was the first successful citizen science example. The typical application is organism monitoring ranging from living organism monitoring to environmental monitoring. For living organism monitoring, the most popular part is related to ornithology whose notable projects are online citizen science projects Neighborhood Nestwatch [17] and Breeding Bird Survey [18] in 1966. Besides, the diversity of bees is monitored in the Great Sunflower Project [19]. The quantity of invasive crab species in the coast of USA is calculated in Invasive Tracers program [20] by citizens and coral reef biodiversity is monitored through space and time by citizen science program [21]. Some projects, such as the Citizen Weather Observer Program [22], focus on environmental monitoring rather than observing living organisms and the timing of cherry blossom has been recorded in Kyoto for 1200 years in citizen science programs.

The citizen science application needs support of citizen science models which witness three stages of development. The first is called science shop model or scientific consulting research model which argues that the problem formulated by amateurs are consulted, verified and modified by a certain science institution [23]. The second model “participatory action research model” suggests that amateurs join in every phase of scientific process together with professionals [24]. The third model is iterative and it created a loop in which amateur citizen and professional citizen verify science research progress and attains better citizen science, which is known as adaptive citizen science research model [25]. Following model theory, the typology of citizen science also takes shape and differentiates citizen science projects based on the criterion of public participation and three classes are contributory, collaborative and co-created [26].
Citizen Science Design Framework

Citizen Science Content Model on Activity Theory
Proposed by Vygotsky, Leont’ev and Luria, activity theory examines collective mediated behavior directly towards an outcome by taking activities as analyzing units [27], and regards expertise as a collective phenomenon and provides an understandable context where activities with tech features take place during the process of design and evaluation [28]. Subject, object, tools, community, rules, and division of labor and the key content elements which form four subsystems including production, exchange, consumption and distribution. [29]

Smart city is a context in which interaction occurs between people and people, people and environment, people and connected technology, as well as connected technology and environment. Main three elements, people, technology and environment discussed here form a collective and collaborative mutual triangle relationship just corresponding to activity theory basic model by seeing subject as people, object as environment and tool as technology. The triangle relationship and three elements as triangle’ three vertexes together make citizen science content model take shape, which is shown in Figure 1. The center, in other words, core of this content model is citizen science design, a kind of activity derived from human activities in activity theory and most importantly, “outcome” in activity theory is interpreted as “new citizen science experience” here that specifically includes better awareness, initiatives, actions, solutions and so on. Therefore, the whole content model can be explained in this way that design aspects including people, technology and environment are synthetically taken into consideration to discover new citizen science experience with the purpose of creating better objects, subjects and tools for citizen science.

![Figure 1: Citizen Science Content Model Informed by Activity Theory](image)

Inspired by our previous research on activity theory principles for urban experience inclusive of Object-oriented, Mediation & artifact, Hierarchical structure, internalization & externalization and Development [30], activity theory principles for citizen science is put forward and embodied.

**Object-oriented**: Citizen Science is citizen-oriented science whose design needs to consider social, technological and cultural factors apart from physical features.

**Mediation & artifact**: Mobile device and social media become new mediation between citizen and smart city.

**Hierarchical structure of activity**: Activity is motive-oriented and composed of actions; user’s needs lead to the motive. Action is the goal-oriented and motive defines the goal of
actions. Action consists of a series of operation [30]. Science design activities can also be decomposed into different design actions which can be decomposed into various design operations and for each action or operation there shall be a variety of interaction design points.

**Internalization and externalization:** Internal mental representations will affect the external interaction, and meanwhile, the external interaction process or pattern can also change people's mental representation [30]. Good citizen science design is not only capable of matching people’s internal minds but also capable of letting people get access to smarter external scientific research ways and broader science scope.

**Development:** Time elapse and environment swift should be concerns for they can change people's behavior and activity and have influence on citizen science design. Besides activity theory principles, the activity checklist is intended to clarify the most important contextual factors of interaction. There are two versions of the checklist, the evaluation version and the design version [31]. The design checklists of research model informed by activity theory model are made up by four aspects: Means and ends, Environment, Learning and cognition and Development. Similarly, the four aspects can be also applied to citizen science design and interaction, which are demonstrated as follows.

**Means and ends:** To identify the main participants of citizen science, and which technology facilitates and constrains the attainment of participants’ goals, what the conflicts between different goals in creating new citizen science experience are.

**Environment:** To integrate physical scientific field, Internet of things and social technology with requirements, tools, resources, and social rules of the environment from the virtual and physical aspects.

**Learning and cognition:** To conclude and analyze people’s cognitive responses to citizen science interface, citizen science service systems and mutual transformations with target technology.

**Development:** To take the developmental transformation of the citizen science as an issue, and explore the more effective citizen science product or platform in a dynamic structure from macro and micro viewpoint.

**Citizen Science Design Model on DSI**

Digital social innovation advocates a type of social and collaborative innovation in which innovators, users and communities collaborate using digital technologies to co-create knowledge and solutions for a wide range of social needs and at a scale that was unimaginable before the rise of the Internet [32]. In the context of digital social innovation which has social, collaborative and connective features, citizen science content model can be further interpreted through adding social properties to “people” element to turn “people” to “social network” and in the meanwhile through endowing holistic concept “technology” with collaborative properties to turn “technology” to “connected things”. Additionally, the concept “community” popular in smart city and DSI gives us suggestions on how to embody “environment”. Considering that citizen science actions and operations are executed in a dynamic geographical spread that has local community, regional community and global community. These communities all play a part as “knowledge or science
containers”. To be specific, we call it scientific field where science is stored, discovered, spread and popularized.

Conclusively, the three triangle vertexes in citizen science content model are respectively changed to social network, connected things and scientific field while the core is still citizen science design and objective is to achieve new citizen science experience as well. All these elements form the citizen science design model is shown in Figure 2.

![Citizen Science Design Model on DSI](image)

The reason why we call it citizen science design model is that during the process of design embodiment of citizen science content model informed by activity theory, there emerge many design chances and challenges when analyzing better design and realization of three model elements in the context of digital social innovation.

Specifically, for social network, the features Online/Offline and Collective/Individual can be applied in view of the fact that there are online and offline social network in which science can be collected collectively or individually. For connected things, the features Platform/Product, Result / Process and Light/Heavy can be applied by considering that connected things can be understood as Internet of Things whose pattern can be platform or product and their deliverables can be result-oriented, a full product or process-oriented, a middleware or collected data. As for Light/Heavy, connected things system can be complex or simplified and operated in a light way which requires less resources or a heavy way which requires more intelligent social computing. For scientific field, the features Original/Reformed can be applied with an opinion that science has original forms such as natural science and reformed forms such as community collective science. The feature Open/Customized can also be an approach in consideration of open science, open data, professional knowledge and customized science. What discussed above is shown in Figure 3.

![Design Features and Design Chances of Model Elements](image)
Citizen Science Evaluation Model

Design activity needs evaluation. Therefore, we propose a citizen science evaluation model based on the elements in citizen science design model and seven pairs of design features. Firstly, pair features Online/Offline and Collective/Individual can be used to evaluate engagement and interactivity among participants in citizen science. Secondly, for design features of connected things, Platform/Product, Result/Process can be used in interactivity evaluation in view of Internet of Things while Light/Heavy plays a part in feasibility evaluation in regard to technology. Finally, as for Open/Customized and Original/Reformed features of scientific field, due to which science accessibility evaluation and science feasibility evaluation is concluded. What analyzed above is shown in Figure 4.

![Figure 4: Citizen Science Evaluation Model](image)

Case Studies

Case1: “ZooseeFun” program and citizen science for zoological knowledge
“ZooseeFun” is a program with the aim to make people/citizen have more convenient and direct access to animal introduction and knowledge on a visit in a zoo, in the wild and in normal life. The overview of “ZooseeFun” program is shown in Figure 5.

![Figure 5: Overview of “ZooseeFun” Program](image)
Citizen science content model of “ZooseeFun” program.

In “ZooseeFun” program, we specify three elements of citizen science content model, “Environment” as “Zoo”, “Zoo” here is a broad concept including physical zoo in city and natural zoo in wild and normal life, “People” as “Animal observers” and “Tech” as “Connection and Recognition”. Four aspects of design checklist of activity theory are used to identify how “ZooseeFun” achieves new citizen science experience.

Means and ends: The first using context is physical zoo and users are positioned as zoo visitors. Due to defects of current science popularization which is confined to boring text descriptions and a few images, more direct, interesting and abundant means for zoological science are come up with thanks to recognition technology and interaction design. The recognition technology enables visitors to attain basic introduction of a certain kind of animal by just taking a photo anytime and anywhere. The interaction design makes science spread in the form of sound, small videos. Visitors obtain zoological science by interacting with application with a positive method rather than a passive way that visitors just read the introduction board and know something limited to do with some animal. The users range is then broadened and extended to animal observers who are amateurs or professionals. They are all allowed to upload information of some kind of animal with a short passage or paragraph of own introduction from an experience view or a professional view.

Environment: Zoological science environment has physical aspect and abstract aspect. For physical aspect, zoo is the place where citizen science is popularized through introduction boards, posters on infrastructures and QR code. For abstract aspect, zoo includes natural zoo, the wild and even normal life. Zoo here is considered as the occasions on which animals can be met or observed.

Integrating communication technology with environment is the key to fulfill new citizen science experience in zoological areas. Take physical zoo as an example, each infrastructure can be a scanning target capable of telling people some part of zoological science after they are scanned by smart phones and additionally each infrastructure is able to be connected with each other to create a scientific knowledge circle which facilitates understanding of multi-part and complicated zoological science.

Learning and cognition: There are many endangered species around the world but people still lack awareness of what they are, where they live and how endangered they are. This program takes advantage of interesting interaction of citizen science interface to get people to better known current station of endangered animals. Consequently, more attention will be paid to protection of endangered animals.

Development: Since animal knowledge is able to be handled so is plant knowledge. The extra functions such as plant science popularization, historical places of interest knowledge exploration can be developed to create a comprehensive citizen science program.

Citizen science design model of “ZooseeFun” program

For three elements of citizen science design model, social network, connected things and scientific field whose meanings in “ZooseeFun” program has been described in content model, the emphasis here is on the design opportunities, seven pairs of design features.
Table 1: Design Opportunities of “ZooseeFun” Program in Design Model

Citizen science evaluation model of “ZooseeFun” program

According to evaluation indexes discussed above, we come up with some detailed evaluation aspects for each evaluation index. For “engagement” evaluation index, the two evaluation aspects are knowledge and experience sharing and offline observation participation. For “interactivity” evaluation index, the two evaluation aspects are human communication with humans or objects and scientific knowledge link among connected things. For “feasibility” evaluation index, the two evaluation aspects are open framework/hardware and big data processing. For “accessibility” evaluation index, the two evaluation aspects are knowledge acquisition ways and knowledge openness. We used the 5-point scale to evaluate the design (1=totally disagree, 5=totally agree). For each aspects, we had two items to evaluate. 16 items were included in the scale (as shown in Table2). When doing the evaluation, we showed the order of these 16 items in random.
Based on these detailed evaluation aspects, we did an evaluation survey among 30 users of “ZooseeFun” program where users give rating for each evaluation aspect. The overall evaluation result is shown in Figure 6 below. A one-sample test was conducted. All the indexes are significant higher than 3 (all \( p < 0.000 \)). So all the indexes are important for design. Interactivity index got the highest score, which indicates that human communication with humans or objects and scientific knowledge link among connected things are very important to people when they visiting the zoo.

![Figure 6: Evaluation Result of “ZooseeFun” Program](image)
Case2: THU Bird – Bird Observation in Tsinghua University and citizen science for natural observation

This research focused on the crowdsourcing application and service design for nature observation by taking the birding activities in Tsinghua University as an example for design research. The aim of this research is to improve nature observation experience, change the time-consuming and indirect learning process into a flexible and instant observing and learning activity, and provide a data source which is crowdsourced, continuously updated and close to users’ daily life. The final solution also improved the recording process for observation to make it more convenient and fast. The overview of this program is shown in Figure 7.

Figure 7: Overview of “THUBird” Program

Citizen science content model of THU Bird

In this program, we specify three elements of citizen science content model, “Environment” as “Campus”, “People” as “Bird observers” and “Tech” as “crowdsourcing”. Four aspects of design checklist of activity theory are used to identify how “THU Bird” achieves new citizen science experience.

Means and ends: This program divides bird observers into four groups, Entry level, beginner level, intermediate level and advanced level. According to observing characteristics of each level, for example, the interest in observing birds on campus, the frequency of observing birds and the familiarity with observing tools, finally users of beginner level and intermediate level are chosen as main users. The young students who are interested in nature history and biodiversity were considered as target users for detailed research on user needs, especially the ones who are active in related student communities. To change the time-consuming and indirect learning process into a flexible and instant observing and learning activity, and provide a data source which is crowdsourced, continuously updated and close to users’ daily life, web application and phone application for bird observing activity are developed and their main functions include recommendation and navigation based on crowdsourcing data map, bird data filtering by
time and location, species identification, bird data browsing and bird data recording and publishing. LBS, database and other ICTs technology make all this functions feasible and create a co-observing behavior and environment on Tsinghua Campus.

**Environment:** It is more appropriate to choose Tsinghua campus as the environment of data collection and experiment. According to the analysis of the distribution characteristics of the wild animals in our country, it is found that there are similar environmental conditions in the campus of Tsinghua University, which is one of the areas where the wild birds live. From the beginning of 2007 to the end of 2013, Tsinghua campus has recorded a record of the activities of 100 different birds, and with the continuing observation of school staff activities, this data is expected to continue to rise.

**Learning and cognition:** There are many bird species on campus but students don’t know what they exactly are and where to observe them. This program makes best use of crowdsourcing data map to show bird data and offer advice for possible observation cites and provide recording tools assisted by species identification to create better citizen science interface to get students to better know current station of birds on campus. Consequently, more students will be attracted to take an active part in observing activity organized by Tsinghua Animal Protection Association thus to further improve awareness of protecting animals.

**Development:** Social platform integration is not a major feature of the design point in bird observation program, but it shows that the use of the current mainstream social media resources in the process of data sharing and resource calls. Users can share data which they are interested in. In the future, the application can also be targeted to grab bird data from social media to be displayed on the map, or through social media to launch a wider range of bird data collection activities and bird data platform promotion activities.

**Citizen science design model of “THU Bird” program**
Seven pairs of design features of “THU Bird” program, the design opportunities are discussed as follow.
Table 3: Design Opportunities of “THU Bird” Program in Design Model

<table>
<thead>
<tr>
<th>Element</th>
<th>Pair features</th>
<th>Design opportunities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Social network</td>
<td>Online/Offline</td>
<td>For online feature, database and data storage makes it easy for students to browse bird data and record bird observation activity, which inspires us to design an online information map on which people get access to bird knowledge in different time, space and technologies. For offline feature, online community helps us to form bird observation offline activity, which inspires us to design message push systems to inform users of offline bird observation activities.</td>
</tr>
<tr>
<td></td>
<td>Collective/Individual</td>
<td>Collective feature and individual feature enlighten us to do users group partition including beginner level, intermediate level and expert level. Enough individual participants record individual observing and publish bird data to achieve new citizen science experience by crowdsourcing.</td>
</tr>
<tr>
<td>Connected things</td>
<td>Platform/Product</td>
<td>Platform feature tells us to create an open and collaborative platform for bird science on campus. Product feature inspires us to notice that smart hardware product for bird science on campus can be a great design choice in the context of Internet of Things.</td>
</tr>
<tr>
<td></td>
<td>Result/Process</td>
<td>Result and process features inspire us focus on not only people’s acquiring bird knowledge, but also the process of bird science acquisition such as where to find observation site, what to do when birds don’t show up.</td>
</tr>
<tr>
<td></td>
<td>Light/Heavy</td>
<td>Light feature means simple and interesting ways to get bird science on campus are needed such as data map and bird data filtering. Heavy feature in this program is abandoned in accordance with light application expectation.</td>
</tr>
<tr>
<td>Scientific field</td>
<td>Open/Customized</td>
<td>Open feature inspires us to create a open but appropriate environment for students to do bird observation. Customized feature inspires us to design application which is able to meet customized bird observation needs such as contextual navigation and message push of bird migration.</td>
</tr>
<tr>
<td></td>
<td>Original/Reformed</td>
<td>Original and reform features remind us to design an iterative bird science systems where bird science is updated from the original state.</td>
</tr>
</tbody>
</table>

Citizen science evaluation model of “THU Bird” program

According to eight detailed evaluation aspects for each evaluation index, 50 Tsinghua university students are chosen to join in evaluation survey. We also used the 5-point scale to evaluate the design (1=totally disagree, 5=totally agree).

The total evaluation score for each evaluation aspect is also set 5 and the overall evaluation result of “THU Bird” program is shown in Figure 8 below. Engagement index got the highest score, which reveals that sharing birds’ knowledge including where and when to observe birds and what birds are in Tsinghua University plays an important role in conducting bird-observing activity.

Figure 8: Evaluation Result of “THU Bird” Program
Discussion and Future Works

We propose a citizen science design framework including a citizen science content model based on activity theory, based on which a citizen design model is taken into shape. We dig out some design points and opportunities. However, there exists variability of participants’ competency because amateurs take part in citizen science projects maybe motivated only by interest which hardly compensates lack of relevant professional skill requirements and it leads to the reality that volunteers vary significantly in their training, accuracy, understanding of project’s aims and ramifications, which has unexpected influence of process of citizen science projects. At the same time, in a stricter view, sampling bias problems are also our concerns because verifying the strict adherence to data collection protocols rarely happens under the circumstances that amateurs aren’t informed of rigid citizen science protocols which they regard as friendly.

In future works, not only should we explore new innovative design opportunities, but also more interesting interactive ways with citizen science projects and surprising feedback such as reward organism are expected to be created to stimulate participants' interest in expressing their thoughts and taking a more active part in scientific process rather than merely browsing and not responding at all, which is a considerable design approach to tackle inequality of contribution. When evaluating whether to fulfill citizen science, four evaluation aspects discussed above are regarded as persuasive factors but what will affect accuracy of these evaluation factors are also vital for building a new citizen science experience evaluation systems. As a result, current citizen science evaluation model is supposed to be enriched by adding extra evaluation variables such as participants' competency and participation continuity.

She has experiences on psychology research including experiments conducting, interview conducting, scale developing and data analysis. She has done poster presentation in the 31th International Congress of Psychology. She has been to Swinburne University of Technology to participate in building a game for assessing old drivers’ ability, and Michigan of University to do culture communication. Besides, she is participating in developing the assessments for students’ abilities, which is a branch of a project of Department of Psychology in Beijing Normal University. She has six-month internship as user experience researcher in Baidu.com Times Technology (Beijing) Co.,Ltd. and now she is an intern in Lenovo. She interests in Big Data and artificial intelligence research.
Interaction Design and Use innovation for Interactive products

Geehyuck Jeong, UNIST(Ulsan National Institute of Science and Technology), Ulsan, Korea, ghjeong@unist.ac.kr
James Self, UNIST, Ulsan, Korea, jaself@unist.ac.kr

Abstract

Product use innovation is a means to facilitate the design-driven innovation approach. We explore how the mode-of-use concept may apply to state-of-the-art product interactions to enhance user experience and provide opportunities for design-driven innovation within the interactive product space. To achieve this we apply taxonomy of interactions to classify interaction styles as along the two dimensions explanatory or exploratory and discrete or composite. Adopting the research-through-design approach two interactive mood lamps were developed and expressed as high-fidelity prototypes. These were then used as stimuli to evaluate the influence of interaction style on product experience. Results indicated the touch-free magic interaction style, an interaction providing explorative and composite modes of interaction, was initially considered more innovative in terms of use. However, participants also expressed negative emotions related to dissatisfaction and embarrassment towards the touch-free magic interaction due to an inability to intuitively understand the use functions. Implications for the application of use innovation within the interactive product context are finally discussed.

Keywords: Use Innovation; Interactive Products; Design-driven innovation

Design-driven innovation is described as a means to add value to new and existing products and their related experiences (Verganti, 2008). This is in contrast with other types of innovation such as market and/or technology-driven innovation. At its core, design-driven innovation aims to radically change the emotional and symbolic content of product experiences, whereby creating new product meanings (ibid). The meaning of a product, within the context of design-driven innovation, is further described as how the user understands and values the product and the experiences provided through its use. By way of an example, one way to achieve a radical change in meaning is through new and novel use and interaction opportunities (Figure 1).
The example of Nintendo Wii (Figure 1) helps to illustrate how new approaches to interaction changed the game playing paradigm; what it means to engage in the console gaming experience. Released in November 2006, the Nintendo Wii offered a physical experience through its use of motion-sensitive controller technology, thus changing the meaning of game play from a virtual experience accessible only by niche markets to an active, participatory experience in the real world for the whole family. The ability to engage in this type of game play is provided by the Wii’s motion-sensing MEMS controller. However, the technology itself was not new at the time of the Wii’s release, having been used extensively in the automotive industry. What made Nintendo Wii an example of innovative use and interaction opportunities as part of a design-driven approach, was the fact that Wii created a radically different meaning to the experience of game playing through the ways in which the system was to be used (Verganti, 2013).

Likewise, Rampino (2011) defines three types of innovation levers; form, technology, and mode of use. According to Rampino (ibid), during the creative process, designers may use these three levers as means to drive design-driven innovation. For example, Rampino’s Form lever indicates an attempt to provide aesthetic value through consideration of semantic product attributes and characteristics (i.e. form, materials, colours and finish). In contrast the designer’s use of the Technology lever provides opportunity for the application of established and/or emergent technologies to drive more innovative products and their associated experiences. In contrast, Rampino’s (op cit) Mode-of-Use level describes an approach whereby new use and function is sort as means to drive innovative product experiences.

Rampino (2011) further suggests the three levers have the potential to facilitate four interrelated types of innovation; aesthetic innovation, innovation in use, meaning innovation and typological innovation. Aesthetic innovation, as defined by Rampino (ibid), is concerned with the product’s external appearance and related personality, seen prior to product interaction. In contrast, innovation in use involves the improvement or modification of the product’s use functionality. Meaning innovation indicates a changing of the emotional and symbolic aspects of a product; what the product means to the user, which is also dependent upon both aesthetic and mode-of-use innovation.
Finally, typological innovation involves the deviation of a product from its formal archetype through radical changes in meaning through aesthetic and/or mode of use innovation.

Comparing the Rampino (op cit) model to the Verganti (2008, 2009) perspective on design-driven innovation, aesthetic innovation and innovation of use are classified as incremental, while meaning innovation and typological innovation is seen as radical. Although the Rampino model is effective in starting to unpack design-driven innovation, the model may be improved through an understanding of how the four types of innovation interact to provide opportunities for what Verganti describes as radically new meaning change (Verganti 2008). For example, how might the design of a smart-product or IoT (internet of things) device implicate a notion of mode-of-use innovation? What possible consequences does this have for endeavors towards design-driven meaning innovation for emergent smart products? With the current study’s aim of understanding how meaning innovation may be applied within the interactive product space, mode-of-use appears to have most significance for the design of new interactions.

A conventional example of mode-of-use innovation is the collapsible kitchen funnel by Copenhagen (Figure 2). The funnel is able to collapse to be stowed away more easily when not in use, thus saving draw space or space in a bag.

![Collapsible funnel by Normann Copenhagen](image)

Figure 2: Collapsible funnel by Normann Copenhagen

However, this then limits the discussion to the application of the mode-of-use lever in conventional product design. Along with emerging technologies, state-of-the-art interactive products consider the product’s mode-of-use as a key driver of their innovative potential. A further example include Canesta’s projection keyboard (Figure 3). Instead of employing conventional inputs such as mechanical switches, the projection keyboard uses a sensor module and projection system to generate projected images of keys. In this way the projection keyboard is an example of Canesta’s application of the mode-of-use lever as driver for innovation in developing a new interactive product.
Although there appears to be clear parallels between mode-of-use innovation and interactive product design, existing studies have not examined the potential of the relationship to provide innovation opportunities within the interactive product space. An analysis of mode-of-use as applied to interactive products could provide the foundations for understanding how mode-of-use innovation strategies can be leveraged during the design and development of radically innovative interactive products. To address this gap, the current study examines mode-of-use innovation within the context of interactive products. We start with a definition of terms and introducing the concept of interaction styles (Buur & Stienstra, 2007) as theoretical framework for our study of mode-of-use innovation with in the interactive product space. We then adopt a research-through-design approach to examine how interaction styles may implicate the user experience, after which results are discussed in terms of the extent to which different interactions may stimulate feelings of mode-of-use innovation as described by Verganti (2008) and Rampino (2011). We finally reflect on results in terms of how mode-of-use relates to interactive product design and the implications of its application as driver for innovation in the interactive product space.

**Interactive Product Design**

Interaction and interface are widely used in the fields of HCI (human-computer interaction) and ID (industrial design). In a study of interactive products, Frens (2006) defines the terms *interaction* as: The relation, in use, between product and its user mediated by its interface. Likewise he describes a user interface as: Combination of the controls and feedback elements of an interactive product. In the design of interactive products of the kind described by Frens (op cit), the means and ways through which interaction takes place have profound implications for the product experience. For the purposes of our exploration of mode-of-use innovation in the interactive product context, we provide a definition of interactive products as products consisted of combinations of controls and feedback elements, thus highlighting important relationship between the product and its use.

**Product Experience**

Desmet and Hekkert (2007) define product experience as a combination of affective and physiological
arousal responses derived from human-product interactions. They indicate the ways in which emotions arise when users encounter products that are expected to be related to their concerns, such as his or her goals or aspirations (Frijda, 1986; Lazarus, 1991). Thus changes in product meaning can elicit changes in the emotional experience of a product. In turn, design-driven innovation can also be seen through the lens of a radical change in the emotional experience of a product. Schifferstein et al. (2012) highlight a relationship between product experience and design-driven innovation, stating that product purchase are becoming more dependent on if the product is able to elicit distinctive product experiences. Again, however, little is said of the relationship between how a product is actually interacted with and used; including implications for product appraisal and resulting assessment of product innovativeness.

The relationship between product innovative and emotional response has relevance for the current study. However, measuring attitudes towards innovativeness through self-report based upon holistic assessment of existing products (Kim and Self, 2013) has its limitations insofar as the product characteristics of particular concern (i.e. mode-of-use) cannot be clearly isolated for focused assessment and analysis. Hence, in the current study, adopting a research-through-design approach, we observe the product experience from the perspective of mode-of-use innovation through carefully designing-in differing interactive opportunities in two otherwise identical products. We then discuss implications for understanding mode-of-use innovation within the interactive product space.

The importance of innovation-of-use strategies has already attracted interest within the human-computer interaction (HCI) field. For example, studies have shown that the interactive quality of a product influences the emotional experience of users. For example, results from a study performed by Lim et al. (2007) illustrated that functional and interactive qualities are significant components in effecting the users’ emotional experience within a given interactive product encounter. The Apple iPod, for example, created idiosyncratic emotional experiences through its unique interaction qualities, allowing users to browse music through a (then) new wheel interface.

Thus, with particular focus upon how the concept of mode-of-use innovation may drive product experience in the interactive product category, our study attempts to address the following research question. How can mode-of-use innovation be best applied to interactive product design as driver for innovation?

**Types of Interactive-product interaction**

In the field of human-computer interaction, Lim et al. (2007) proposed a comprehensive framework to describe interactivity by providing a set of interaction attributes. Although the framework has seen application in the design of interactive artifacts (Lim, 2011), its scope is too broad for the current study as it covers various designs from GUI-based to physical-based products. Since the concept of design-driven innovation itself has its roots in industrial design, we further examined existing work in the area of interactive product design and identified the concept of interaction style, defined as a mode of interaction between human and machine based on a particular technology (Buur & Stienstra, 2007).
To this end, Buur & Stienstra (ibid) define pairs of dichotomous interaction styles along the two dimensions of explanatory vs. exploratory and discrete vs. composite. Explanatory interactions provide directions for goal achievement. In contrast, exploratory designs focus on playful interaction rather than the goal itself. The volume control button on a TV’s remote controller can be seen as explanatory interaction design, while gestural control in the Nintendo Wii is exploratory, providing opportunities for more playful interactions. In contrast, discrete interactions provide links between one control and one function, whereas composite interactions have general controls to access various functions. Traditional radio controls, with their various knobs are used to adjust volume and sliders to select radio channels can be seen as discrete interactions. A smartphones home button, with its various functions can be seen as composite. With these criteria, four generic interaction styles of interactive product-user experiences can be described (Table 1).

Table 1 Generic interaction styles of user-product interactions.

<table>
<thead>
<tr>
<th>Interaction Style</th>
<th>Descriptor</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Tangible Control (discrete/explanatory)</td>
<td>The interface consists of several, discrete controls. The spatial arrangement of these support product understanding.</td>
</tr>
<tr>
<td>2. Elastic Play (discrete/exploratory)</td>
<td>Specific controls for specific functions. The interface consists of a wide variety of general control types. Interaction supports physical input and feedback. Learning to interact with the product requires both cognitive and embodied understanding.</td>
</tr>
<tr>
<td>3. Rhythmic Logics (composite/explanatory)</td>
<td>Interaction requires a cognitive understanding of the product. Input is a rhythmic sequence of simple actions, button tapping for example. Interaction focuses on efficiency and feedback; is digitally mediated.</td>
</tr>
<tr>
<td>4. Touch-free Magic (composite/exploratory)</td>
<td>The product reacts in surprising ways. The controls themselves may not have one clear identity. The product supports an exploratory mode of interaction, may move and respond physically, but with no tactile feedback.</td>
</tr>
</tbody>
</table>

As extremes along the explanatory/exploratory and discrete/composite dimensions, the current study compares the two interaction styles: Tangible Control (TC) and Touch-free Magic (TfM). An example of TC can be seen in the Elecom Shining Bluetooth Speaker by Elecom (Figure 4).
The Elecom speaker utilises a visual effect, with buttons mapping onto each of the product’s functions. This then provides opportunities for direct information related to the product’s use. A comparative example of a Touch-free Magic interaction (TfM) style is seen in The Cloud, designed by Richard Clarkson Studio (Figure 5).

In contrast to the Elecom Shining Bluetooth Speaker, The Cloud utilizes a music-activated visualizing speaker with a motion-triggered lightning & thunder performance, employing embedded motion sensors.

**Research Methods**

An empirical study was designed to assess the participants’ emotional response to the two interaction styles TC and TfM. Adopting a research-through-design approach, an interactive product (mood-
lamp) was developed and prototyped. In order to examine the influence of the interaction styles a version of the lamp was designed according to a TC interaction, with a second identical lamp developed and prototyped with an interaction based upon TfM control. The interactive mood lamp was chosen as stimuli to examine implications of interactive control for use experience. Through interaction participants were able to control color (red to blue) and brightness (high/low). Each of the two product stimuli were designed according to the two interaction styles. The Tangible Control (Figure 6, right) interaction style was designed with the purpose of giving information for successfully carrying out certain functions. Two knobs to control brightness and color were applied to the interactive mood lamp.

![Figure 6: TfM stimuli (left) & TC (right)](image)

Touch-free Magic (Figure 6, left) was designed with a minimal user interface, providing interaction with unpredictable feedback.

**Measurement of responses**

A questionnaire consisting of 14 bipolar semantic differential scales (based upon the PrEmo tool for capturing emotional product response, Figure 7), was used to gather response data. To achieve this, responses were recorded through 5-item Likert scales (i.e. 0: “I do not feel this”, 1: “I feel this a little”, 2: “I feel this somewhat”, 3: “I do feel this”, and 4: “I do feel this strongly”). In order to examine the effect of each interaction style on the product experience, participants were subsequently asked a set of open-ended questions to generate qualitative data to explore rationales behind Likert-scale responses.
Research Process

20 subjects participated in the study ($n=20$). Undergraduate student participants were recruited from the authors’ institution, varying in their majors to limit the influence of educational background. The average age of participants was 24, with a range of between 20 and 28. The sample group consisted of 9 males and 11 females. Figure 8 illustrates the experimental procedure.

![Figure 8: Procedure of study.](image)

Participants were initially provided the two design prototype stimuli, randomized to limit order effect. For each stimulus subjects were given two minutes product interaction time. Participants were then told to complete the 14 semantic response scales. Upon completion of the first session,
participants were provided a short break and the process repeated for the second stimuli. After the participants completed the interaction with both designs, they engaged in an interview session to discuss their response to the Likert-scale questionnaire. These final sessions typically lasted five to ten minutes (Figure 11). The overall process was completed in approximately 30 minutes.

Results

Comparison of positive responses

The participants’ responses when engaging each of the two design stimuli (TC & TfM) were examined to calculate the sample sum (Σ), mean (M) and standard deviation (SD), derived from recorded Likert-scale responses. Table 2 compares results for the seven positive emotion scales included in the study (items P01.-P07.) between the two stimuli (TC & TfM).

Table 2 Comparison of results across positive emotion scales.

</tbody>
</table>

Mean (M) differences across the seven positive response items (Table 2) are further illustrated in Figure 9. The vertical axis illustrates mean scores, derived from the sum Likert-scale response across the sample. The horizontal axis shows the seven positive response indicators.
As can be seen from Figure 9, the TC (tangible control) product interaction type received a higher mean score for response items: P01. Desire (M = 2.35), P02. Satisfaction (M = 2.85) and P04. Hope (M = 1.8). In contrast, the TfM (touch free magic) attracted higher mean responses for items: P03. Pride (M = 2.5), P06. Attractiveness (M = 2.95) and P07. Admire (M = 2.25). Of the TC interaction’s higher Mean response scores, P02. Satisfaction received the greatest difference in response (TC, M = 2.85, TfM, M = 1.8), followed by P04. Hope (TC, M = 1.8, TfM, M = 1.25). This would indicate the TC interaction type provided a more satisfying mode-of-use compared to TfM interaction. Moreover, the TC interactive type also appeared to provide greater opportunities for feelings of ‘hope’ in interaction compared to the TfM interactions. For the higher Mean response scores of TfM interaction, P03. Pride (TC, M = 2.0, TfM, M = 2.5) and P07. Admire (TC, M = 1.75, TfM, M = 2.25) received the greatest difference, followed by P06. Attractive (TC, M = 2.55, TfM, M = 2.95). This may indicate that the TfM stimuli was able to stimulate satisfaction due to its ease of use, but unable to surprise. In contrast, while the TfM interaction stimulated feelings of admiration, what was not seen as so satisfying in its mode-of-use.

Comparison of negative responses

As above (Table 2) Table 3 shows results from the participants’ responses to the seven negative
response indicators (N01.-N07.) when engaging each of the two design stimuli (TC & TfM). The table illustrates results as sum (Σ), mean (M) and standard deviation (SD), derived from recorded Likert-scale responses.

Table 3 Comparison of results across negative emotion scales.

<td>3</td>
<td>0.48</td>
</tr>
<tr>
<td>N07.Contempt</td>
<td>1</td>
<td>0.05</td>
</tr>
</tbody>
</table>

As with the positive response indicators (Figure 9), the seven negative responses received differing mean scores between the two stimuli. Figure 10 further illustrates these differences. Again, the vertical axis records mean participant responses across the seven negative response scales, while the horizontal axis indicated the seven response indicators (N01.-N07.).
As indicated in Figure 10, the TC product interaction received a higher mean score for response scales Bored ($M = 0.65$) and Sad ($M = 0.48$), although scores for both these indicators were low for each of the two stimuli. Likewise, the TfM interaction style attracted higher mean responses for five of the seven negative response scales, although mean scores were low across all bar one. For response indicator N02.Dissatisfaction, the mean response for the TfM control type was $M = 1.4$ compared to the TC control ($M = 0.45$). This result indicated that negative emotions may not have been stimulated in interaction with the two control types, with the exception of dissatisfaction. This may suggest that the TfM control appeared to simulate moderate levels of dissatisfactory mode-of-use interaction compared to the TC stimuli.

**Statistical analysis and comparison**

To further analyze differences in mean scores between the two stimuli (TC and TfM) across the positive and negative emotional response scales, a statistical analysis was run. To achieve this a *Mann-Whitney U Test* was conducted with the seven positive and seven negative response indicators as independent variable, and the intensity of product interaction experience as dependent variable (indicated through mean score). For the significance value gained from the *Mann-Whitney U Test*, the exact significance value was used, since the asymptotic results may not be valid. The
result showed that, among the 14 positive and negative response indicators, one positive (Satisfaction (U=75, p<0.01) and two negative (Dissatisfaction (U=86, p<0.01) and Shameful (U=150, p<0.05)) were significantly different.

<table>
<thead>
<tr>
<th>Response Indicators</th>
<th>Mann-Whitney U Test Result</th>

</thead>
<tbody>
<tr>
<td></td>
<td>U</td>
</tr>
<tr>
<td><strong>P02.Satisfaction</strong></td>
<td>75</td>
</tr>
<tr>
<td><strong>N02.Dissatisfaction</strong></td>
<td>86</td>
</tr>
<tr>
<td><strong>N04.Shameful</strong></td>
<td>150</td>
</tr>
</tbody>
</table>

In terms of negative response indicators, and as indicated in Table 3, N0.2 Dissatisfaction (U=86, p<0.01) and N04. Shameful (U=150, p<0.05) were significantly increased for the TfM interaction compared to the TC. In other words, the intensity of both dissatisfaction and shamefulness was significantly higher for the TfM interaction. This may suggest interacting with the TfM stimuli may result in dissatisfaction in its mode-of-use. This is compared to significantly increased satisfaction (P02.Satisfaction, U75, p<0.01) when interacting with a TC control. It may be that a TfM interaction stimulates significantly increased dissatisfaction, compared to the satisfaction of a TC control. If this is the case, our findings indicate a relationship between satisfaction and the application of mode-of-use as lever for innovation within the interactive product space. Likewise the significant difference in shamefulness response scale indicates that interaction with the TfM control may have resulted in the stimulation of shame. If could be that participants felt embarrassed or awkward in their inability to effectively use the TfM control to achieve the lamp’s function (illumination and hue).

**Qualitative results**

To further examine the probability of a relationship between the interaction styles and the stimulation of satisfaction/shame emotions and implications for mode-of-use innovation within the interaction context, we examined the participant’s qualitative responses taken at the end of the session (Figure 8, Stage 04. Interview Session).

This examination appeared to reinforce our statistical analysis. For example, when discussing interaction with the TC product stimuli, subject 16 appeared satisfied with the interaction’s natural mode-of-use commenting, “I feel more satisfied with this (TC) because the interaction is more natural”. On the other hand, the same participant comments on the TfM interaction suggested a more dissatisfied experience, “This (TfM) shows less credibility than the one with the knob.”
Likewise, subject 18 also appeared to evaluate the TC interaction as a more Satisfying product experience compared to the TfM control due to its intuitiveness, “I feel more satisfied with this (TC) because it’s more intuitive.” However, like participant 16, subject 18 was less satisfied with the TfM interaction suggesting, “In order to interact with this (TfM) you have to think a bit. That’s making me feel less satisfied.” These qualitative responses indicated further a relationship between satisfaction and novelty in mode-of-use within the interactive product space. For the novelty provided by the TfM interaction, paradoxically, made it less satisfying in terms of its ability to meet the subjects’ expectations towards functionality, resulting in a dissatisfying product experience.

In a related way, it appeared feelings of dissatisfaction also may have lead to shame in the participants’ ability to effectively interact with the product to achieve the desired functionality (illumination and hue). For example, subject 13 indicated the ways in which an inability to understand the interaction leads to feelings of embarrassment, “I felt ashamed because when I first got this (TfM), I didn’t know what to do with this.”. This indicated, as with the link between satisfaction and a negative product experience, novelty in mode-of-use paradoxically lead to feelings of embarrassment.

For subject 17, the very novelty of TfM’s mode-of-use appeared to move from dissatisfaction to feelings of resentment, “If I ever buy this (TfM) that would look pretentious and silly, because buying this is like spending money on something that’s doubtful whether it would work or not.” As these qualitative responses indicated, results suggest relationships between emotions stimulate during product experience and interaction styles within the interaction space. That is to say, when applied to the interactive product context, mode-of-use as theoretical construct to drive innovation, also has the potential to stimulate negative feelings associated with embarrassment and dissatisfaction.

Discussion

This paper has explored the application of mode-of-use (Rampino 2011) as driver for innovation in the interactive design space. Following a research-through-design approach, two conceptual interaction styles, TC (tangible control) and TfM (touch free magic) were identified within the literature. These were then applied to the design and prototyping of two product stimuli, which were subsequently used to drive an empirical study. The study employed the two prototype stimuli (TC & TfM), with their corresponding embedded interaction styles, to derive emotional responses from participants through 14 five-item Likert-Scale response scales. This was followed by an interview session.

Results indicated the TC and TfM interaction styles elicited different emotional responses across the seven positive and seven negative response scales included in the empirical study. A further statistical analysis of these differences found, of the 14 response indicators, three stimulated significantly different responses towards the two interaction styles: P02.Satisfaction, N02.Dissatisfaction and N04.Shameful.

In the section above we posed the following research question: How can mode-of-use innovation
are best applied to interactive product design as driver for innovation?

As indicated by Rampino (2011), mode-of-use innovation is characterised by the novel application of use affordance to provide improved function. Performed correctly this then has the potential to stimulate meaning change to drive radical design-driven innovation (Verganti 2008). However, our findings indicated the limitations of novel interaction types within the context of interactive product design. Specifically, we have identified a relationship between the more novel TfM control and product dissatisfaction. Specifically, a TfM interaction style appeared to stimulate significantly increased product dissatisfaction compared to a TC interaction. These results appear to indicate a relationship between the application of mode-of-use, as lever for innovation within the interaction space, and dissatisfaction.

As novelty in mode-of-use is positioned as a theoretical construct to stimulate product innovation, we see our findings as paradoxical. In embedding a novel mode-of-use, results have indicated a concurrent increase in feelings of dissatisfaction and shameful embarrassment towards the TfM interaction. Thus, the employing mode-of-use, as described by Rampino (ibid) as driver for innovation within the interactive product space, requires careful consideration of how novelty in mode-of-use may be reconciled with an ability for the interaction to intuitively achieve a required functionality.

Moreover, if satisfaction is derived from a usefulness appraisal (particularly within the interactive product context), a nonconscious evaluation of an event as to whether it supports or obstructs users in achieving their goals, appears critical to the perceived success of the interaction. As Desmet (2011) indicates, products can be appraised as helpful for reaching these goals, but if the sequence or relationship between interaction and resulting product reaction is hindered, users can experience frustration (Desmet, 2011). While intuitively, the TfM interaction was new to the participants compared to TC, this novelty may not have stimulated feelings of radical innovativeness due to the participant’s inability to achieve their interaction goals. Those considering mode-of-use, as described by Rampino (2008), as approach to drive mode-of-use innovation in the interactive product space, designers would do well to consider the particular requirement of interactions to achieve a desired product reaction unambiguously.

The qualitative data from an interview conducted at the end of each empirical session provided further evidence to indicate how the novel TfM interaction resulted in feelings of frustrated dissatisfaction.

Thus our findings have indicated that the TfM interaction, intended to stimulate awe and surprise through its new mode-of-use, as its name “touch-free magic” suggests, also paradoxically hindered and frustrated participants, leading to dissatisfaction. From these results it can be inferred that, in the application of mode-of-use innovation in the interactive product context, particular consideration must be made to how novel and unique interactions must balance an overriding necessity for clear understanding of how interactive opportunities achieve a desired product function.

The novel and experiential qualities of products are becoming more important for market success,
and therefore companies may innovate their business by aiming to deliver specific experiences (Schifferstein, Kleinsmann & Jepma, 2012). However, our empirical findings suggest applying mode- of-use innovation through new interaction styles, although appearing at first an effective way to provide unique and potentially exciting new user experiences, requires careful consideration for how mode-of-use as conceptual anchor for innovative design must also consider relationships between interaction and associated product reaction that are well aligned with user expectations.

Conclusions

Although the study of use innovation within the interactive product context remains a work-in-progress, results provide certain implications for knowledge of use innovation, and helpful considerations for designers in practice. However, further studies are now required to examine the effect of interaction styles upon design-driven innovation. For example, how do other interaction styles implicate responses towards use and function when applied to interactive products? What role does experience (of interaction) have in defining a response (positive or negative) to interaction and what effect does this have for feelings of mode-of-use innovativeness? How can mode-of-use innovation best be achieved within the context of interaction design, considering its requirement for clarity in terms utility and function? In addressing these questions designers will be better able to navigate the often contradictory requirements of expected functionality and unexpected novelty within the design of more innovative, as well as satisfying interactive product experiences.

Abstract

This submission reports a design-driven integrated innovation on EV mobility, EV 3.0, as a collaboration between design research institution and a small BEV company in China. The on-going project provides a novel vision and design strategies of Battery Electric Vehicle (BEV) and mobility and has achieved a key technological performance on rapid charging of BEV. The current situation of BEV Industry and their recharging patterns show a big gap of new energy mobility. Key issues of BEV and mobility are defined by analysis of users’ need of mass market and a case study of a leading BEV. Usability of charging is identified as a bottleneck of BEV industry. Hence a new vision and scenario of rapid charging are defined, leading to respective design strategies and technological routines. With a long term investigation and iterative prototyping, an established prototype is developed and officially tested in the National Center of Supervision and Inspection on New Energy Motor Vehicle Products Quality in Shanghai. The test result indicates that the prototype has 431 km range in speed of 80km/h with only 15 minutes’ recharging, which provides a valid routine to break bottleneck of BEV industry.

Keywords: Integrated innovation design; Sustainable mobility; Battery electric vehicle; Rapid charging;

With pressing challenges of energy and environment, new energy mobility is widely proposed by main countries and international bodies as a key strategy of sustainable development. In China, new energy vehicle is defined as one of seven strategic emerging industries in “Energy-efficient and new energy vehicle industries development plan (2012-2020)” (China National Energy Administration 2012) to keep energy security and to reduce its carbon emissions, followed with a series of policies and plans to promote it in national and local levels. Battery Electric Vehicle (BEV) is regarded as a major promising industry in the field according to technological advancement and Chinese energy situation. Although China is becoming a leading country in BEV with governmental supports in industrial policy and planning, the entire current solution is still far from application for mass market (Liu, Wang &Ari 2014), particularly in personal consumption market. Given that, EV 3.0 project reported in this paper aims to discover new opportunities of integrated innovation by collaboration between design agency and industries.
Project definition

Previous research indicates the key factors constraining BEV industry are capacity of battery, economic cost, recharging infrastructure (Liu, Zhang & Liu 2014). Therefore, major industrial concerns focus on battery technologies with large scale investment on the one hand, and major policy recommendation is public recharging infrastructure construction. However, the overall situation of BEV industry hasn’t progressed efficiently or sufficiently. Hence, EV 3.0 project doesn’t stand on those key factors, instead it returns to user’s potential needs in the perspective of human-centered design, to discover new opportunities and paths for breaking bottleneck.

EV 3.0 project recognizes that in the perspective of technology, BEV is not continuation of traditional vehicle, but a disruptive solution. Hence, a design-driven innovative approach is employed to redefine problems, redesign scenarios and reshape mobility system. The project starts from user needs identification from three perspectives including usability, safety and economy in order to define the key challenges of marketing. According to the defined challenges, project investigates the industrial context in recharging models and a case study of a leading brand to understand better the bottleneck of industry. Afterward, a new vision of BEV system is defined with multiple scenarios of recharging services and design strategy of BEV, which approaches to new ideas of technical innovation. Furthermore, it goes with iterative process of design and prototyping to reach designing objective of defined vision.

User needs identification

To understand user needs is fundamental for problem definition and concept generation. User research is well recognized as essential design research to investigate users’ need. In practice, user research, particularly quantitative user research, might be rather effective when it supports projects of optimization design or incremental innovation than when it does radical innovation projects. In the field of BEV mobility, BEV and related services have appeared for decades while it’s still tiny if looking at the entire market and industry. As a potentially promising industry with not-well prepared solutions, to develop a valid system in this sense is a disruptive innovation with discontinuation of traditional vehicle and mobility. Therefore, average user research may easily enter detailed level of observation and finding, therefore, we need a designerly way of user needs investigation to look out a big picture of BEV and mobility.

On the foundation of comprehensive research on EV industries, markets and users, we look into the basic needs of general users of mass-market. Both traditional or BEV mobility, their values to user are near to each other. Hence, three perspectives include usability, safety and economy are defined to investigate the basic needs of potential users of BEV.

(1) Usability: key factors of usability of BEV are range, accessibility of recharging service and recharging time. With technological advancement in battery and lightweight, range is largely improved and reaches general range of traditional vehicles. While there are still obvious gaps in accessibility and time of recharging.

(2) Safety: besides of normal safe factors of vehicle, the safety of BEV mainly depends on that of battery. With progress of battery, Battery Management System (BMS) and battery pack, the safety of BEV is also enhanced well with relatively high risky perception.
(3) Economy: comparing to traditional vehicle, BEVs have huge economic advantages both in using cost of energy and production cost. The major part of price of BEV are cost of battery. Under the governmental tax and subsidy policy for EV battery industry, the price of BEV largely decreased.

Therefore, usability of BEV is proposed as a bottleneck of BEV industry. Current recharging system and model could not meet the basic needs of potential customers. In another word, current BEV and recharging system are not a real valid solution. How to increase the efficient of recharging and decrease the charging time to fit the psychological perception and behavior habits are key challenges of BEV mass-scale development.

**Context of BEV industry**

Since recharging system is recognized as weakness of BEV industry, it’s important to understand well current situation of it. In global, Chinese sales of new energy vehicles in 2016 are 507,000 in total, including 409,000 all-electric vehicles and 98,000 plug-in hybrid vehicles (Liu 2017). China is the largest country whose stock of new energy vehicles with cumulative sales of more than 951,000 units until December 2016. These figures include passenger cars and heavy-duty commercial vehicles both. As matter of fact, fast development of BEV industry in China is largely driven by government policy with public subsidy (Wang, Liu & Ari 2014). Moreover, the majority of purchased BEVs are distributed in public fields like Buses, Taxi or sanitation trucks, where the recharging system and service can be organized according to respective specific service systems.

**Current recharging models**

Either in public sectors or personal markets, recharging system and service are fundamental infrastructure for application of BEV. As an emerging industry, there are several models in parallel exploration, mainly including normal plug-in model, battery swap model and fast recharging model.

(1) Normal plug-in model: it’s a normal model for average passenger cars. It’s a long time recharging for 8-10 hours by low power input in average environment like houses or communities. The system solution is relatively simple, solid and economic. The model fits the scenario of commuting.

(2) Battery swap model: This model shifts recharging time and place out of BEV by swapping battery. It’s a centralized system with united management for a quick solution for car. It requires a large scale infrastructure, particular support of grid and high compatibility of standards. This model usually fits public or commercial mobility systems like bus and taxi.

(3) Fast charging model: This model employs high power input to recharge in 20 mins-2 hours in public recharging stations. The solution is not well prepared with negative impact to grid. The model mainly fits the scenarios of emergent recharging.

So far, there are different strength and weakness respectively between three models. From the viewpoints of user needs, fast charging model would be the best. While the technological solutions are not solid and it only can be the supplement of other two. Normal plug-in model obviously couldn’t meet the user need comparing to traditional vehicle. Although tree models have some complimentary advantages, they couldn’t provide valid system and service for large-scale of BEV in future. The market and industry call for
a new scenario and solution of recharging system.

A case study

Although BEV solution hasn’t met the basic need of mass market users, major automobile companies and new energy vehicle companies all over the world continue launching new BEV with progress advancement to test and incubate personal consumption market. Tesla targets high-end market by rising up driving performance, safety, smart digital system and user experiences. It employs creative and strong strategy in branding and marketing to cover the limitation of recharging. Instead, some Chinese companies like BYD focuses on middle range market. With advantage of battery technologies and policy support, it quickly opens fresh market with average solution.

Given that, as defined above, the usability of recharging system and service is bottleneck of BEV industry. A serious case study was done with Tesla as a leading company in BEV. It continues having advancement in recharging solutions including normal plug-in model at home and fast recharging model in Tesla super-charging station. In the later solution, the recharging time could be reduced around 1 hour. The designing highlights of Model S¹ include: (1) Integrating battery pack into chassis optimizes structure and stability, and utilizing aluminum alloy materials for chassis reaches better light weight design. (2) Advanced BMS and large-scale battery pack consisting of Panosonic NCR 18650 battery balance factors between stability, capacity, recharging speed and economy. (3) A complicated temperature control system of battery pack protects temperature sensitive battery.

What we learned from deep study of Tesla Model S: (1) among power batteries, NCR 18650 Ternary Li-ion Battery has performance of fast recharging, with potential for faster recharging system if temperature is better controlled; (2) In fast recharging solution, high power generates large quantity of heat. Hence, heat management and temperature control are a key difficulty of battery pack; (3) aluminum alloy material has good quality in strength, density and thermal conductivity and could potentially play unique role in safety, lightweight and temperature management of BEV. Those finding from case study may support a new vision.

New vision, scenarios and strategies

A new designing vision

Since usability of BEV, particularly recharging time are the key factor of user need in mass market, how much time of recharging is acceptable? Tesla develops a fast recharging model with a specific network of super-charging stations. However, one hour or even half an hour recharging time are still far from the psychological perception and behavior habit of users comparing to traditional car. Although in the perspective of key technologies, BEV is a discontinuation of gasoline car, in the perspective of users, they are two similar transportation tools with same using values in everyday life. Hence, if recharging time of BEV could be near to the time of refueling time of gasoline, BEV industry would have sound conditions for mass market and large scale development. According to basic user

¹ http://www.teslamotors.com
needs and assumption of recharging, a new vision of EV 3.0, “Rapid Charging Model (RCM)” is defined: (1) Range more than 350 km; (2) Recharging in 15 minutes; (3) Centralized charging station network; (4) Solid battery safety. In this novel vision, users could recharge their BEV as convenient as gasoline car refueling. People may easily shift the using scenarios of gasoline car to BEV. In the vision of RCM, there are two clusters of key factors. One cluster focuses on charging infrastructure and service; another one focuses on BEV, including range, charging time and battery safety.

Scenarios building of charging services

Since RCM model is near to gasoline refueling in user perspective, the scenario of rapid charging station could be also near to the gasoline station. However, the gasoline station network has been built for decades or hundreds of years so that the density of distribution is sufficient for everyday life use. To balance the diffusion of BEV and rapid charging station network, alternative scenarios are proposed in the vision of EV 3.0.

(1) Super-charging station. It’s a typical centralized station like gasoline station with high power input and efficient recharging in 15 minutes, located in urban and high way (Figure 1). Users may would have similar experience as well. Even so, in the front stage, there is a unique parking system with rapid charging function to increase the capacity of charging vehicle. In backstage, there is big storing battery pack as power bank, which inputs electric power during peak valley at night and outputs during recharging in day-time as a distributed power network.

(2) Mobile-charging station. It’s a mobilized super-charging station by adapting into a power station truck (Figure 2). It has less capacity and power. While it could move to almost any places according to situation of needs. It’s a dynamic service as an effective supplement of super-charging station network particularly when it’s not sufficient or some emergent situations.
(3) Normal plug-in stand. As at beginning, centralized station network would be not enough for a long-term, utilizing the normal household or public charging stand is also positive supplement, especially for commuters (Figure 3).

A new design strategy of BEV

As defined in previous discussion, related factors of rapid charging system include lightweight, battery capacity, temperature control and strength of battery pack. Among them, range mainly depends on battery capacity and lightweight; charging time mainly depends on battery capacity and temperature control; and battery safety mainly depends on temperature control and strength of pack (Figure 4). Therefore, the key factors of RCM are lightweight, temperature control and strength, which exactly matching the unique attributes of aluminum alloy in density, thermal conductivity and strength.
Therefore, a new strategy of integrated innovation is defined: to build an integrative chassis platform with battery pack by aluminum alloy material and process to effect key factors by its natural attributes and advantages. Finally, a passive heat balance system is created to reach the temperature control (Figure 5).

![Figure 5: passive heat balance system of super chassis platform](image)

1 Chassis; 2 Battery Pack; 3 heat conduction; 4 heat emission

**Prototyping and a new concept**

According the new vision of EV 3.0 and defined strategy of BEV, a long-term research and development of rapid-charging oriented BEV has been done by jointed project team. After iteration of functional prototyping (Figure 6), finally the jointed project team developed a prototype reaching the objective criteria of RCM vision. The final prototype has an integrative chassis platform with integrated battery pack as the key of innovation. Corresponding BMS is also developed and other parts of vehicle are purchased from third parties. In addition, a specified charging stand for RCM is also developed for its test.
The prototype vehicle of EV 3.0 was tested by the National Center of Supervision and Inspection on New Energy Motor Vehicle Products Quality (www.smvic.com.cn) in Shanghai. The test is conducted as 80km/h speed method on the drum to provide the test data according to GB/T18386-2005, EV energy consumption rates and range test methods. The results indicate: (1) Curb weight (kg): 1750; (2) Charging time: 15 minutes; (3) Charging Quantity(kwh): 65.2; (4) Range (km): 431 (Figure 7-8). The test result reach major key objectives of new vision of EV 3.0.

Figure 7: test report of EV 3.0 car prototype_a

Figure 8: test report of EV 3.0 car prototype_b
On the foundation of RCM system and prototype, a new BEV concept is proposed as a concept design toward a specific target to explore new possibility of final product. The defined target user is core family of urban middle class, and the define BEV is a SUV for their everyday life, as a third space between home and companies or schools with multiple functions and rich user experiences (Figure 9). Comparing to traditional vehicle, the new concept indicates a simpler structure and more flexible spaces depending on the integrated chassis platform of EV 3.0 (Figure 10), which leads a new proposal of car exterior and interior (Figure 11-12).
Conclusion

EV 3.0 regards the BEV is a discontinuation of gasoline car and redefine the vision of BEV mobility according the basic user needs as a big picture. A car prototype with breakthrough innovation were developed to reach the new vision of RCM. As an on-going collaborative project, there are lot to be done for complete systematic solution and further car design and development of BEV, while the current results and outcomes so far is already valid to envision new possibility of BEV mobility and create new industrial opportunities. EV 3.0 is a design-driven integrated innovation. Facing complex challenges of BEV mobility, the collaborative project team employs interdisciplinary and human-centered approach to reshape the problems and integrate different opportunities for disruptive innovation.
Acknowledgement

The project reported in this paper is a long term collaboration between DESIS Lab of Jiangnan University and Jiangsu Duke New Energy Automobile Co., Ltd with strategic partnership. Thanks to all participants of two partners and other stakeholders. It largely depends on a long exploration on sustainable and EV mobility in DESIS lab as one of main research tracks. Thanks to all colleagues, students, visiting professors and guess professors who involved into related research and teaching activities. The project also had advices and supports from China Academy of Engineering major consulting project “Innovative Design Developing Strategy” (2013-2016) and National Social Science Foundation major project “Green Design and Sustainable Development” (13ZD03).

Designing Language Learning for Migrant Workers’ Workplace Integration

Young-ae Hahn, Yonsei University, Wonju, South Korea, yahahn@yonsei.ac.kr
Nyamsuren Gombodoo, Yonsei University, Wonju, South Korea, nyamka16@naver.com

Abstract

The number of migrant workers in South Korea is on the rise, but their inadequate Korean language skills prevent them from being promoted at work, or fairly treated as respected members of the society. In this study, in collaboration with a government-authorized language educational facility for immigrants, the authors investigated (a) challenges in migrant workers’ Korean as a second language learning, and (b) design principles of lessons and learning materials specifically targeted to their needs. Student and teacher interview data confirmed that the workers’ limited time for study, weak motivation, Korean colleagues’ indifferent attitude, and limited teaching resources at educational facilities are major barriers to achieving higher levels of linguistic skills. From the data, the authors identified four design principles: personalized content, community participation, portability of materials, and micro learning modules. Informal lessons via Facebook, factory safety signs, and portable writing drill booklets are designed as on-going experimentations of the principles.

Keywords: social integration, second language learning, migrant workers, participatory design

According to 2015 statistics (Park, Hwang, & Song, 2016), immigrants in South Korea account for approximately 3.4% of the whole population. In G province where the authors reside, 22.9% of all immigrants are E-9 (non-professional employment) visa holders from China and other Southeast Asian countries; they are taking over manufacturing and agricultural jobs that Koreans do not prefer. Despite the Korean Fair Labor Standard Act (2008), labor exploitation cases are often reported. Lee (2016)’s study with 752 migrant workers in K province concludes that they work 62 hours per week on average, which leaves virtually no time for language learning.

Inadequate language skills entail major problems for the workers. Firstly, their job competency is undermined: workers who do not understand terminology spoken in their professional fields, and details of the entire production process cannot be promoted to managerial positions. They can only be assigned to simple, repetitive manual tasks. Secondly, migrant workers are not accepted as valued members of a society, if they do not have “insights on practice, products and perspectives of the target culture” (National Standards, 2006, as cited in Hahn & Rodriguez-Kaarto, 2015). In short, the workers need focused trainings on occupational terms, and cultural knowledge to actively participate in local communities. Are they, indeed, studying Korean language they need?

In collaboration with an educational facility located in G province (hereafter, N center) where free government-funded Korean weekend classes are provided for immigrants, the authors investigated:

2. Design principles of lessons and learning materials specifically targeted to the
workers’ needs and circumstances.

Before reporting specifics of research design, the authors would like to review unique characteristics of Korean language first, to exemplify a beginner Korean learner’s frustrations.

**Theoretical Backgrounds**

**Why Korean Language Is Difficult to Learn?**

Korean is an agglutinative language that belongs to the Altaic language family. Various affixes are added to change meanings and implications of sentences. Shin, Kiaer, and Cha (2013) describe the difficulties of learning Korean: while Hangeul, the phonetic alphabet of Korean, is easy to learn with its scientific design, Sino-Korean lexicon (i.e., words written in logographic Chinese letters) that make up about 60% of the vocabulary generates numerous homonyms that sound and look alike in Korean. This implies that learners will frequently face words that can be interpreted in many ways. Native Korean speakers manage to interpret them in context, but beginners cannot do so.

Another difficulty arises from affixes that conjugate according to the preceding nouns: what part of speech they belong to, how they are pronounced, or what the whole sentence means. For instance, learners need to attach the right adnominal suffixes to verb stems among -ㄴ/은, -는, -ㄹ/을, depending on the tense (past, present, or future). Learners find it difficult, so often they compose incomplete sentences by removing all affixes and simply arrange nouns and verbs, making listeners guess what they mean.

Lastly, learners will observe seven levels of speech forms that “indicate the level of formality” (“Korean speech levels”, n. d.), or honorifics that reveal the speaker’s relation to the audience. This trait reflects the Confucian tradition in Korean culture where respect and filial piety matter in social relationships. For an immigrant worker, speaking on the right level of formality is critical in maintaining good relationships with superiors and colleagues, but it is also challenging for most learners, so they learn to speak on a moderate level of respect to all, to be safe.

In short, Korean learning requires significant number of hours to be familiar with vocabulary, affixes, and speech formality. Migrant workers, however, are expected to learn the language within a short period of time and be able to carry out given tasks at work. Then to expedite the learning process, how the design of lessons and learning materials can be? The authors turned to literature on contemporary theories of L2 learning for insights.

**Cognitive, Ecological, and Task-Based Approaches in L2 Learning**

The cognitive and ecological approaches are contrasted in Järvinen (2009, as cited in Hahn & Rodriguez-Kaarto, 2015): the cognitive approach (Krashen, 1982) perceives learning as a product that precedes in a linear, fixed, coherent, and analytic manner based on linguistic inputs the learner receive. In the ecological approach (van Lier 2000; 2004), learning unfolds in a non-linear, dynamic, complex manner in the learner’s interactions towards or reactions from the semiotic environment.

Despite their different philosophical grounds, the two approaches bear ostensible
similarities in their recommendations. In previous studies, the authors have proposed six principles of L2 learning system design (Rodriguez-Kaarto & Hahn, 2014) from the two approaches: learning in action and interaction, lessons that challenge the learner, interaction with More Knowledgeable Others or MKO (Vygotsky & Cole, 1978), direct-indirect perception and language affordance, multimodal-multisensory perception, and the learner’s self-concept. In essence, the principles require hours of exposure to the target language-culture, and natural interactions with native speakers in a democratic learning environment.

The principles, however, are hardly applicable to migrant workers’ Korean learning due to their quite unique, challenging circumstances. The authors’ preliminary study revealed that migrant workers spend most of their time working on manual tasks that do not require strong linguistic abilities. Due to excessive working hours, they do not have time to visit various places other than work and home. Their colleagues are native Korean speakers, but not all of them are willing to accept the workers as their equals or help them learn Korean language. The workers are not motivated to achieve higher levels of language skills because perceived social mobility is low for them.

As an alternative, the authors hypothesized that if the workers see the practical values of speaking Korean language, they will be motivated to study on a regular basis. With another approach, Task-Based Language Teaching (TBLT, hereafter), the authors set up a short-term learning goal of mastering occupational terminology for migrant workers. Ellis (2009, as cited in Bygate, 2015) defines task as an activity where the learner can find pragmatic meanings and clear goals to achieve by using the language. The learner carries out the task by filling up gaps left for her (collecting necessary information, e.g.), with her own resources. With the TBLT approach, students are speakers, not learners, of the language (Van den Branden, 2006). Planning a TBLT syllabus requires a thorough learner needs analysis with real-world examples, to ensure “the learner’s genuine uses of language” both in class and in practice (Bygate, 2015).

What follows in the next section is a description of design of research activities conducted to investigate specifics of migrant workers’ learning and living circumstances, and to explore how Korean lessons and materials should be designed to meet their needs.

**Research Design**

In total, over 21 weeks of time, the authors worked with 26 students at N center for class observation, in-depth interviews with students and teachers, and online data collection via Facebook.

**Classroom Observation**

The research team participated in all levels of N center classes for observation. The 31 hours of time was also critical in building rapport with them. As a participating organization of Korean Immigration and Integration Program (KIIP, hereafter), N center provides Korean courses every Sunday on four proficiency levels (beginner, intermediate, advanced, and social integration). The program is government-funded; instructors strictly follow authorized syllabi and textbooks.

26 students are enrolled (21 migrant workers and five marriage migrants) to the program at the time of this research. On each day, students can attend three 90-minute class sessions
(4.5 hours); it takes 200 hours of attendance to pass the beginner and intermediate levels respectively, and 70 hours for the advanced level before getting certified. The KIIP certificate gives various advantages in naturalization or visa extension process, so students who intend to work in South Korea for a longer period of time regularly attend classes. Their behaviors, language proficiency, reactions to lessons, interactions with the instructor, questions and learning strategies are observed along with what instruction methods are used.

In-Depth Interviews with Students

Among the 26 students, nine participants sat for in-depth interviews (Table 1). Their language proficiency levels span from beginner to advanced. Five groups of questions are discussed:

1. Demographic information: age, education, and residency in Korea.
2. Workplace as a learning environment: current and past occupations, weekly working hours, Korean coworkers’ attitudes towards them, job satisfaction, occupational language specific to the job, if they have received sufficient safety training, and cases of occupational accidents in the past. Such information is relevant to designing learning contents targeted to each workplace, including accident prevention safety signs.
3. Private life and topics of interests: current and future hobbies, places they visit frequently, activities they enjoy other than Korean learning, and their experience of socializing with Koreans. Such information is relevant to personalized learning contents.
4. Experience with Korean learning: the most challenging part in learning Korean, and personal learning strategy to cope with it.
5. Experience with N center: how they found the N center program, and among various activities at N center, which they prefer? This question asks what motivates migrant workers to gather at N center every week, because the center provides other activities besides Korean classes.

### In-Depth Interviews with Experts

With teacher participants, five areas of questions are discussed:

1. General information: work experience in years, and organizations they work for.
2. Teaching expertise and experience: what level of classes they teach, and who their students are (nationality, occupation, gender, age, and Korean proficiency).
3. Teaching strategy: teaching methods they recommend for migrant workers.
4. Observations: what personalities and backgrounds are relevant to a student’s learning progress, what motivates them to advance to higher levels, what causes early learning plateau for them, and how to overcome it.
5. Opinions on alternative approaches: for instance, trying different contents such as Korean cultural products (drama, K-pop) as learning material/activity, advanced Korean learner’s role as MKO, or task-based learning.

In total, five teachers working for N center, and the K center administrator participated (Table 2). The authors contacted administrators as well, to learn from their years of statistical observations (e.g., yearly dropout rates, or trends in the students’ nationalities).

### Online Data Collection via a Facebook Group

To collaborate with N center students during weekdays, as well as to provide them informal learning materials on cultural knowledge, the authors set up a Facebook group (https://goo.gl/EzXQde) where all members can freely upload photos/videos. Facebook is chosen as a platform because all students were already using Facebook mobile app to get in touch with their family members at home. The authors’ intention of running the group is posted in six languages (Korean, English, Vietnamese, Cambodian, Russian, and Nepali) for beginner Korean learners. The group started with 19 students and a teacher at N center as members, and it has been in operation for 16 weeks. Now 62 members either voluntarily post questions and contents, or react to the authors’ postings of news articles, cultural contents, and supplementary Korean learning materials.

### Discussion of Findings

Challenges in Immigrant Workers’ Korean Learning

Table 2. Description of expert participants
The authors’ interviews with teachers and students at N center revealed that the learner’s limited time for study, and their weak motivation prevent them from developing Korean linguistic competencies further. Moreover, due to limited teaching resources, providing personalized lessons on occupational terminology is difficult.

**Limited time for studying and socialization:** Often immigrant workers’ abovementioned long working hours prevent them from (a) regularly attending free government-funded education programs, and (b) engaging in social occasions with native Korean speakers. Concerning working hours, seven out of nine student participants reported that they are either required or voluntarily (because, on weekends, hourly pay is higher) to work on weekends until 5 pm or later. A teacher states:

“The majority of students at J center work for 6 days per week. They only have one day to rest, but still they come to study here. They did not even have time to visit Seoul yet. They just commute to work and K center.” (TP 06, from personal communication, February 3rd, 2017, Translated from Korean transcription)

The teacher also pointed out that the employer’s perception and attitude towards migrant workers affect their learning progress. Some employers encourage Korean language learning on Sundays because they expect the workers to translate for newly-hired colleagues; others discourage it because their perception of the workers is *uneducated, low-paid labor who are only capable of repetitive tasks*. Many workers at N center could not name the machine they operate at work, revealing that they have been working without proper terminology training.

Tough work schedules lead to limited interaction opportunities with native Korean speakers. Time shortage and/or lack of linguistic competency prevent workers from making new Korean friends outside the work, so their knowledge of Korean society and culture is confined to workplace and colleagues. A student (SP 05) commented that the majority of his colleagues are “too old to be friends with him”, which might discourage him from proactively engaging in their conversations. It is a detrimental learning environment on many levels. Not only the workers need to practice Korean more during weekdays, they need to be exposed to Korean speakers other than their colleagues, to develop a broader understanding of the society, and have meaningful conversations on the topics of their interests. The workers’ colleagues at factories may be native Korean speakers, but the authors suspect their attitude towards migrant workers are not always supportive; a student reported that one of the frequently spoken sentences at work is “한국말 못 알아들어요? (Can’t you understand Korean?)” Besides, some Korean factory workers are not ideal conversation partners for beginner learners; according to the authors’ private observations, the language they speak often includes dialects and vulgarism not suitable for beginner learners.

In summary, due to busy work schedules, N center students cannot develop linguistic abilities further and their social interaction opportunities are limited. This phenomenon may adversely affect their future careers: Sung, Kang, and Kang (2015) concludes that a migrant worker’s Korean ability, and the number of their Korean and immigrant friends are factors positively correlated to wage levels, because with higher linguistic abilities and wider personal network, the worker’s access to better-paid job position improves.

**Learner’s weak agency and early learning plateau:** Some learners do not wish to
continue after acquiring essential Korean to get by, because their work do not require higher linguistic competence. The majority of participants said body language worked just fine, implying that tasks at factories are close to manual labor, not intellectual assignments. SP 04 who is working for a kimchi factory said “여기에서 하는 일 그렇게 어렵지 않아요 (what I do at this factory is not that complicated).”

Simultaneously, the workers are not motivated because they do not expect to move higher up the ladder of success in South Korea. In response to an interview question (“Do you know anyone from your home country who have successfully settled in Korean society?”), seven out of nine participants could not name one. In fact, Korean broadcasting media frequently portray success stories of highly-educated westerners and happily married migrant women, while regarding migrant workers, cases of exploitation (e.g., non-fulfilment of work contracts) are mostly highlighted. Regarding this phenomena, a teacher participant at J center commented:

“Because [the workers] came here for money, […] they do not want to learn Korean further if they can take care of basic necessities […] To motivate them, you need to show […] success cases of migrant workers […] and what is possible if you are fluent in Korean. You need to show that.” (TP 06, from personal communication, February 3rd, 2017, Translated from Korean transcription)

One problem incurring with the early learning plateau is migrant workers’ weak writing skills. The authors oftentimes found misspelled words in their writing, a typical phenomenon among L2 learners whose learning activities are centered around listening and speaking, not reading and writing; they only remember phonetic patterns of words that are sometimes different from how they are spelled. Learners who hit early learning plateau will stop reading and lose opportunities to see correct spellings of words, or sentences with complex structure. Cumulatively, this leads to weak reading and writing skills.

**Limited teaching resources:** Abovementioned weak writing skills is linked to what is expected from students at work. A teacher mentioned:

“For them, [because they are expected to begin working at factories upon arrival] teaching survival Korean is a priority, so we spend more time listening and speaking than writing.” (TP 01, from personal communication, February 7th, 2017, Translated from Korean transcription)

For this reason, current government-designed Korean curriculum for immigrants emphasizes speaking and listening, even on advanced levels. If students want to study further beyond conversational Korean, they are left on their own.

Another challenge incurs with the characteristics of Korean occupational terminology: what tools and processes exist at each workplace. Learning the terms is a priority for migrant workers, but it is difficult in reality because language teachers do not feel comfortable teaching them. A teacher participant mentioned:

“…so when [the workers] say press, they know what it means and what process is involved with it because they have used it at work. But teachers like us, we just know it is some kind of machine that puts pressure on something, but we do not know exactly how it works.” (TP 06, from personal communication, February 3rd,
A significant portion of terms spoken at factories are loanwords with foreign origins, pronounced with Japanese and Korean accents. It is a unique phenomenon due to the Japanese Colonial Period in South Korean history.

“We do not feel comfortable with teaching some terms spoken at construction site, they are remnants of Japanese Colonial Period. [Korean teachers] do not understand them, […] so cannot teach them.” (TP 06, from personal communication, February 3rd, 2017, Translated from Korean transcription)

Providing occupational terminology lessons is difficult at educational facilities because teachers are not familiar with it. Moreover, it is not practical to expect teachers visit all workplaces and learn their unique terminologies. Teachers are supposed to follow government-authorized language programs and prepare students to pass TOPIK (Test of Proficiency in Korean) exams.

In conclusion, the migrant workers’ limited time for study, weak motivation, and limited teaching resources are major challenges. Such circumstances call for different learning approaches and materials customized to their needs.

Future directions of lessons and learning material design for migrant workers
From the interview data, the authors found tentative principles for syllabus and material design: personalized contents, community participation, portability of materials, and microlearning modules.

Personalized contents: Beyond grammar lessons, migrant workers need occupational terminology, knowledge on Korean social infrastructure systems, and cultural knowledge to be integrated in local communities. As each person speaks on different proficiency and is interested in various topics, the lessons for advanced learners can be personalized, with topics chosen considering her work environment and cultural interests: where the learners work, what tasks they do, what they do on holidays, and what aspects of Korean culture they are concerned about. Currently the N center runs small classes of less than 7-8 persons per group. Teachers are well aware of each student’s living and working circumstances, and that knowledge is easily reflected on examples teachers use during the class to prompt students’ voluntary responses.

Community participation: Topics such as workplace jargons are better taught in situ, not in the classroom. Also, the best teachers of the subjects are the workers’ supervisors and colleagues. Designing learning materials for occupational terminology requires the workplace community’s participation: employers’ deep involvement in the planning stage, and the colleagues’ contribution to tutoring activities. While Park and Kim (2014) pointed out that a migrant worker’s satisfaction at work and the quality of relationship with colleagues positively correlate to how fast this person can be integrated to the society, findings from student interviews indicates that Korean colleagues at most factories are not enthusiastic in offering helps. New concepts of syllabus and learning materials are called for, to induce Korean colleagues’ voluntary-involuntary tutoring.

Portability of materials: The learner’s living pattern—working 6 days per week—might not leave them time and energy to study for extended periods of time during weekdays. The authors explored portable designs of learning materials they can carry around and use
during short breaks between shifts. A portable learning material with task-based lessons also opens up opportunities to acquire genuine and practical cultural knowledge while interacting with other Koreans in the community they live in. Kim and Kim (2013, as cited in Park and Kim, 2014) conclude that immigrants are refraining from being active members of the local community because of language barrier, cultural differences, and discriminatory acts they may experience. While it is true that some Koreans show hostile and prejudiced attitude towards them, immigrants should be encouraged to be proactive in making acquaintance with Koreans to build up linguistic abilities and break wrong cultural stereotypes.

**Microlearning modules:** Contents of the portable learning materials can be also designed considering the short periods of time the learners can afford to study. Microlearning engages the learner in brief, focused sessions to avoid information overload. Such an approach let “[t]he learners [be] in control of what and when they’re learning”, by delivering short contents written with one learning objective in a straightforward manner (Eades, 2014). Micro learning modules typically last between 3 to 6 minutes, and suitable for “quick revision” or “[building] upon previous content”; microlearning contents are suitable for being played on mobile platforms (Andriotis, 2016). With such an approach, the authors intend to train migrant workers to build the habit of practicing 1-2 new expressions they learned at N center every day, composing sentences they need at work and in the community they live.

**Design Explorations**

In this section, the authors will describe how insights gained from research activities are applied to learning activities and material design. The foci of all materials are teaching occupational Korean terms. Topic ideas are collected from the students’ participatory inputs. Some lessons are designed in the format of short writing drills, and delivered in portable formats.

**Occupational Terminology Lessons**

The research team is currently providing personalized lessons on occupational terminology via Facebook. To find out what terms workers do not understand at work, the authors conducted in-person interviews, and set up a Facebook group where N center students are invited to post their questions with photos. ICT technology such as Facebook groups was particularly effective in reducing the knowledge gap between participants and researchers, and grasp each learner’s personalized needs. Students who are active on Facebook shared their personal and professional interests.
A participant (SP 05) working at an auto parts factory posted 24 pictures of tools he has been using daily, without knowing their names (Figure 1). It was somewhat surprising that he did not try to ask his colleagues, and no one at the factory attempted to teach him what the tools are called either. Even though the authors have not worked in this industry, resolving his questions was not impossible. In reference to the brand logos and serial numbers printed on each tool, both the tools’ English and Korean names, and where to find/buy them online were found. Later, for SP 05, the authors designed one-page summary of all tool names with pictures, which SP 05 brought back to the work and asked his colleagues’ confirmation. Later at N center, other students working in similar lines of work also wanted to get personal copies of the list.

This activity was an experimentation of a learning material where content is personalized with the learner’s participatory inputs, and where a community of native Korean speakers (such as SP 05’s colleagues) participated in a tutoring role, even though their contribution is minimal at this moment.

**CNC Machine Safety Label Redesign**

One type of the occupational terms students need is safety signs at work, especially signs with complicated concepts that are not sufficiently understood with pictograms. Safety sign example data are collected via Facebook. SP 05 also posted signs that are specifically designed for a CNC machine, about a part called bar feeder. The authors closely worked with him to find out how the machine works and what he understood as potential sources of danger. Captions attached to the sign warn specifically about accidents caused by bars protruding out from the machine (Figure 2, #2), while SP 05 was more concerned about strong wind suddenly coming out from a tube out of his experience.
The authors redesigned two separate warning signs for his factory, one for the accidents caused by a rotating bar end, and the other for the accidents caused by strong wind. In Figure 2, #4 is the final warning sign against touching the tube on the left side, and #5 warns about accidents caused by rotating bar end. During the several iterations, SP 05 made a sketch of how a drainage tube is connected from the bar feeder inside the machine in detail (Figure 2, #3) to assist the authors. In this activity, SP 05’s participation brought up a potential source of danger in operating CNC machine that no one has noticed before.

**Portable Korean Writing Drill Booklets**

After classroom participation and interviews, the authors became well-acquainted with students over 21 weeks of time: their occupations, personal interests, and where they need more work for Korean learning. With such information, every week the authors design microlearning modules of vocabulary, expressions, composition and writing drills (Figure 3).
Topics and example sentences reflect students’ current occupations and personal interests. For example, SP 05 frequently posts video clips of him playing guitar on Facebook, so the authors designed a grammar drill page with relevant content for him. Some pages are designed around artifacts, tasks, and events that are relevant to manufacturing processes at factories. Other pages show Korean cultural, climate, or daily events students can relate to. In Figure 3, on the left, a student composed new sentences: “The manager made me work until late night” and “My son uses cellphone too much”, revealing what is happening in her work and private life. Every week, the authors collect completed pages from students and post corrections of their answers via Facebook (Figure 3): red parts are corrected to better expressions written in blue.

The booklets are distributed in two formats: copies of printed booklets are delivered to N center every week, and PDF files of the booklet are freely distributed to all members of the Facebook group. Printed copies are favored by some students because they are small enough to carry around in pockets, sentences are printed in large font, and pages are large enough to write on. PDF files are favored by some Facebook group members who do not come to N center but still want to practice Korean.

Conclusions

In this study, the authors investigated (a) challenges in migrant workers’ Korean as a second language learning, and (b) design principles of lessons and learning materials specifically targeted to their needs. Student and teacher interview data confirmed that the workers’ limited time for study, weak motivation, Korean colleagues’ indifferent attitude, and limited teaching resources at educational facilities are major barriers to achieving higher levels of linguistic skills. Interview findings provided insights on design principles for learning materials — personalization of contents, community participation, portability of materials, and microlearning modules — following which safety signs and writing drill booklets are designed for the workers. Design experimentations on the principles are on-going with workplace manuals for migrant workers. The manuals are co-designed with advanced learners for each factory, to borrow from their experience of what they wish they had known as new foreign employees.
The findings in this study are limited in that currently all research activities are designed to gain insights on occupational terminology lessons, so the other area of cultural knowledge needs to be addressed in separate future studies. The findings are also limited in that not all student participants are fluent enough to partake in task-based learning activities with native Korean speakers at the moment. With a long-term plan, the authors are providing lessons to enable them to carry out more conceptual and complicated assignments.

In future studies, experimentations of design principles will be expanded. For instance, community participation that calls for Korean factory workers’ in situ tutoring is a promising concept in teaching occupational terms, but how to get them involved, and how to motivate workers to be proactive at work in asking help are two big behavioral design goals of future studies.

Nyamsuren is currently a doctoral candidate at Yonsei University, South Korea. She holds a MFA in Visual Communication Design from Inha University, South Korea and a Bachelor of Design Science in Industrial Design from Chonbuk National University, South Korea.
Cultura: A communication toolkit for designers to gain empathic insights across cultural boundaries

Abstract
Designing successful products and services that people like, requires an understanding of the context and the aspirations of those people. Over the past decade, a range of methods has been developed to help designers gain such empathy. These have worked well when designer and target user share a cultural context. However, designers often find it difficult to empathize with the user insights of individuals from a culture beyond their first-hand experience. To help designers step beyond this limitation, those user insights need to be placed in a larger understanding of the cultural context. In this paper, we present Cultura: a toolkit that uses nine cultural aspects based on cultural models, informing designers about user insights in a broader cultural context. The toolkit was evaluated in design sessions with four design teams. The findings indicate that Cultura provides inspiration and motivation for designers to gain empathic insights into users beyond their own cultural boundaries and to make effective designs for people.

Keywords: Cultura, communication, user research, generative techniques, design tools, persona

Products and services are sold increasingly in the global market. Over the past decade, the value of trade in products as well as in commercial services has nearly doubled (WTO, 2016). Until recently, designing for people in other cultures was mostly done by international companies from developed countries. But increasingly, companies from developing countries are also designing products and services for overseas markets and users/customers. One example of this is Huawei, a Chinese networking and telecommunications equipment and services company, whose products can be found in more than 140 countries worldwide, such as in Europe, the Middle East, and Africa (Huawei, 2015). This global trend has made the designer’s job more challenging than ever. These companies and designers want their products to provide users/customers a fulfilling experience. To do that, they need to see their offerings ‘from the users’ side’ (Fulton Suri, 2003), where more and more, that user comes from a different culture than the designer.

Understanding user experiences and gaining empathy with users has been the goal of much research in the past two decades (Bruseberg & McDonagh-Philp, 2001; Fulton Suri, 2003; Mattelmäki, 2006). Many companies have adopted empathic communication techniques, such as using personas (Pruitt & Grudin, 2003) to
represent their users/customers as people, and empathic research techniques such as contextmapping (Sleeswijk Visser, Stappers, van der Lugt, & Sanders, 2005) to obtain data for the personas. In most reported work, designers and users/customers have been from the same culture, so this understanding could build on a tacit shared basis. But when designing for (and trying to understand) customers from very different cultures, design teams can fail to recognize the importance of the empathic triggers these techniques bring. For example, in a cross-cultural design project the first author conducted about bathroom products, Chinese user insights were obtained and communicated to a Dutch/German design team. One user was quoted as, ‘I used my first salary to buy my parents a premium bathroom product to show them my love and devotion.’ This anecdote was not appealing to the design team at first, until they learned about filial piety, a core cultural value that explains the close and affectionate ties between children and parents in China. This example shows that such user insights need to be viewed in a larger cultural context.

The goal of this research is to develop structured tools for designers that augment techniques such as personas, adding a larger social-cultural background to the often individual and anecdotal perspective of user insights. We first reviewed the literature on empathic design methods to select tool formats, and culture theories to select nine aspects of culture. These were included in a communication toolkit called Cultura, similar to the goals of persona but anchored in cultural context. Next, the toolkit was evaluated in two sessions where design teams used the Cultura toolkit to generate informed design proposals. Finally, we discuss how the toolkit and approach can contribute to achieving cross-cultural empathy in design projects.

**Literature review**

Design literature has shown that a growing attention has emerged to develop Human Centred Design (HCD) methods and techniques that uncover the life situations, needs, and values of people from other cultural contexts (Christiaans & Diehl, 2007; Lee, 2012; van Boeijen, 2015). On the basis of psychology of empathy, Kouprie & Sleeswijk Visser (2009) proposed that empathy is best achieved through a process in which the ‘empathizer’ (read: designer) not only studies the perspective of the ‘empathee’ (read: user), but also reflects on his or her own experiences in the area studied.

Literature also suggests taking cultural diversity into account when applying design tools and methods. Lee (2012) suggests that any method is ‘culturally bounded’ in the HCD field, so that design researchers should not fail to recognize the local situation where a method is applied. Techniques such as personas (Pruitt & Grudin, 2003), scenarios (Nielsen, 2004), and contextmapping (Sleeswijk Visser et al., 2005) have been tailored to support designers to gain empathy with users from other cultural contexts (Hao, van Boeijen, Sonneveld, & Stappers, 2017; Vestergaard, Hauge, & Hansen, 2016; Walsh, Petrie, & Zhang, 2015). These techniques are mostly used to communicate user’s needs, emotions, and values from the individual perspective. However, Lee (2012) argues that a cultural context not only contain the traits or behaviours of the individuals, it is collectively formed by people in and through their everyday activities. Techniques that place the individual at the centre can cause the relatively invisible social and cultural values to be overlooked, leaving the designers ill informed.
To go beyond the limitations of approaching user context from an individual perspective, techniques for a broader understanding of the social (Postma, 2012) and the cultural (van Boeijen, 2015) aspects have evolved for gaining empathic understanding of the intended users. Postma (2012) created Sociona, a technique triggering designers to focus on person-to-person social interactions. Sociona tackles the social aspects of 3 to 4 people (e.g., parents taking care of children), but it does not address the larger scale of cultural aspects (e.g., how respect for the elderly is a more fundamental value in some cultures than others). Likewise, van Boeijen (2015) applied cultural models to explain practices, behaviours, as well as tangible manifestations, such as artifacts that a group of people have developed over time, to help designers towards creative solutions. One of her findings is that these theoretical cultural models need to be tailored to the ‘language’ that designers can recognize.

Designers need a practical support to deal with the complexity of gaining empathy with people who are physically and culturally distant. However, concrete tools that communicate from individual user experience (UX) to a broader cultural understanding are missing. In this study we develop and evaluate such a toolkit.

**Research Methods**

To create the toolkit, we followed three steps: (1) Analyzing cultural models, (2) designing the toolkit, and (3) evaluating the toolkit in the field with designers. Each of the steps is described below.

(1) Analyzing cultural models
To provide designers with a cultural basis, our experience suggested that components would be needed such as composition of cultural groups, their shared values, and how these values are expressed in daily practice. We reviewed the cultural models mentioned in van Boeijen (2015) and Postma (2012), because they have been successfully used in design practice. From these, we selected components that were promising for inclusion in a hands-on design toolkit. Selection criteria were that they could be illustrated with appealing examples, and did not require elaborate introductions.

(2) Designing the toolkit
The toolkit was designed for use in a design workshop setting, informing and inspiring designers and encouraging discussions. To make it practical, it was scaled for use in a one-day workshop, by a design team whose members are not trained in cultural theory. Such a toolkit for communication should be flexible, and easy for designers to access, sort and share (Sleeswijk Visser, 2009). Following Rodriguez, Diehl, & Christiaans (2006) we decided to include both descriptive (e.g., background information) and experiential (e.g., scenario, video) user information. The cultural aspects selected in step (1) were given the form of a cultural wheel (explained in the results section).

(3) Evaluating the toolkit
The toolkit was evaluated with user data gathered in China. This data was analysed, and the resulting UX insights were communicated to design teams with the help of the Cultura toolkit (shown in Figure 1). The design brief was ‘to design products and services enhancing university students’ social relationships in China’. The Cultura tool...
toolkit includes two sets of data: (1) user data gathered specifically from the target group for the design topic at hand; (2) cultural information selected from theories to contextualize the user data.

Figure 1. Overview of the tools in the Cultura toolkit (details in Figures 3 and 4)

Gathering user data for the toolkit in China
The user data were gathered from 26 Chinese students from a university in Shanghai using the contextmapping technique (Sleeswijk Visser et al., 2005). Participating students worked through a sensitizing workbook on the theme of ‘me and my university life’ during one week. Also, each of the students recorded a 1 to 2 minute-documentary video clip (Raijmakers & Miller, 2012) to showcase his/her living environment at the university: the dormitory room, a shared residential room for four students of the same gender. Then, the students took part in a focus group interview with one of the researchers. Each of the three focus groups lasted about 2 ½ hours. All focus groups were video recorded and transcribed. Two of the three researchers analyzed the user data and translated them into UX insight examples, using an on-the-wall card-sorting technique (Sanders & Stappers, 2012). The insights were described in the form of cards and video clips (the second and third tools in Figure 1).

Design sessions with the toolkit in the Netherlands
The design sessions were conducted in the Netherlands with 14 master design students or recent graduates who had similar levels of design experience. The students had grown up and received their education in European countries: The Netherlands (10), Germany (1), Turkey (2) and Italy (1). They formed 4 design teams and each team was with three to four design students to enable in-depth discussions. Each design session lasted approximately three hours.

In order to find out whether reflecting on their own experience would aid the design process (as suggested by Kouprie & Sleeswijk Visser), two design teams in session B received a sensitizing workbook a week before the session. In it, they were asked to reflect on their own experiences in the area of ‘student life’.

Each session began with a half hour introduction about the toolkit. The design teams received and studied the printed cultural wheel (the first tool in Figure 1, for details see next section). For the rest of the first half hour, they were shown a set of 4 video clips from step (1). They had been asked to write down observations about the user context shown in the videos. After the video clips, the design team clustered their first observations as groups. In the next hour of the session, the team received the set of 72
insight cards, clustered according to the *cultural wheel*. The designers studied the cards and came up with design ideas. Each group was asked to select one idea and develop that into a concept in half an hour. Following idea generation, the design teams presented some of their ideas and were asked to indicate which insight cards and cultural aspects they had used to generate their concepts. At the end, all designers were interviewed about how they experienced the overall process, and about their experience of using the toolkit (see Figure 2).

**Figure 2.**
In the evaluation, two design teams A only used the *Cultura* toolkit, two other teams B prepared with a sensitizing workbook.

All sessions were video and audio recorded, and transcribed. The first and second authors conducted the analysis by using the on-the-wall card-sorting technique (Sanders & Stappers, 2012).

**Results and Discussion**
In this section, we first report the findings of cultural model analysis, followed by the results of toolkit design, and then evaluate the toolkit.

**(1) Results of analyzing cultural models**
As mentioned above, we needed elements from theories that could be translated to design tools for the *Cultura* toolkit. Out of several models and approaches mentioned by van Boeijen (2015) and Postma (2012), we selected two that appeared to have these qualities: Engeström’s model of an activity system (AS) (2001) and Hofstede’s onion model (OM) (2005, p.7).

Activity Theory is a cultural framework that explicates the structure, development, and social-cultural context of people’s activities (Kuutti, 1996). Engeström (2001) models an activity system as six components that explain the what, how, and why of people’s behaviours in their social-cultural context: *subject*, *object*, *artifacts*, *rules*, *community*, and *division of labor*. The *subject* is a person or a group who strives to achieve an *object*. The *artefacts* are mediated tools or symbols that are used to facilitate the performance towards these *objects*. The AS indicates that a cultural context consists of *rules* (written and unwritten), the *community* (a group of people who share values and meanings), and the *division of labor* (how roles of the group members are divided). Activity Theory argues that one needs to take all these components into account to develop a meaningful understanding of the human psyche.
Hofstede’s OM (2005) illustrates that values are the core but invisible part of culture manifested through cultural practices. It explains that in discovering the values of a culture, one needs to first peel off the outer layers of rituals, heroes, and symbol.

Our selection from these theories had to form a practical tool for designers. This meant we needed to adjust and simplify the language and the complexity of the models. For example, where Engeström talks of ‘artifacts’, designers are more familiar with ‘things and products’; instead of ‘subjects striving for objectives’, designers are more likely to speak of ‘users trying to achieve their goals’. Regarding complexity, both of the theories not only explicitly explain each component mentioned above, but also discuss the relationship between the components. For our toolkit, we decided not to elaborate on the relationship, but the toolkit should invite its users to address such combinations if they thought them appropriate.

As a result, a structure consisting of 9 cultural aspects was built based on these models. Table 1 below presents these aspects, indicating from which model(s) /component(s) each aspect was derived. We added a final aspect, Macro developments, even though it was not in the models, because the designers not only need to understand the importance of the current culture, but also those of the trends and developments that influence people’s everyday lives.

Table 1: The descriptions of the nine cultural aspects and their related models

<table>
<thead>
<tr>
<th>Cultural aspects</th>
<th>Descriptions</th>
<th>Related Components and Models</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Socio-cultural values</td>
<td>Values are the social standards concerning what is acceptable and what is unacceptable, important or unimportant, right or wrong, workable or unworkable, in a cultural context. Individual values may differ from those of groups.</td>
<td>Value (OM)</td>
</tr>
<tr>
<td>2 The Material World</td>
<td>The material world is composed of artefacts (products, or things which have been designed). These artefacts, also called material culture, not only have utilitarian functions, but also carry particular symbolic meanings. They have social significance that refers to a specific group of people, or a specific time and place.</td>
<td>Symbol (OM) and Artifacts (AS)</td>
</tr>
<tr>
<td>3 Community</td>
<td>A community is a group of people who have a shared concern or who wish to reach a goal, and interact regularly to do so. The community distinguishes who/what does or does not belong to the group. However, the scope of the community varies with different design projects. Designers need to decide how to delineate (set the border) for each project.</td>
<td>Community (AS)</td>
</tr>
</tbody>
</table>
### 4 Division of Roles
The division of roles describes how duties are distributed among community members. For example, what the activities are and how they are distributed according to people’s position in the hierarchy; whether it is a collective or individual activity; and division of roles by gender.

### 5 Rituals in everyday lives
Rituals are sequences of collective activities to reach desired ends, which are considered as socially essential. This also includes daily routines, special events, and activities in people’s spare time.

### 6 Knowing the rules
Rules, in the context of culture, consist of written and unwritten (social) agreements created by people during shared practices in order to achieve a goal. They deal with people’s social relationships and are continuously being formed and changed, reflecting the nature of the culture.

### 7 Angels vs. Devils
An angel represents a person (perhaps a super hero or celebrity) who is highly esteemed in the community, and who can also serve as a role model. Of course, the opposite can also exist – a devil (an enemy, or anti-hero). It is even possible for a person to be seen as both angel and devil by different parties.

### 8 Goals of end users
The end users’ goals describe the short- and long-term goals that users want to achieve, or personal intentions that are meaningful to them or their community (in a specific context).

### 9 Macro developments
Macro developments describe contextual factors such as developments in demography, economy, and politics, including the composition of the population, geographical characteristics, development of infrastructure, and so on.

(2) The results of toolkit design
The final design of the communication toolkit includes 3 tools already indicated in Figure 1 above: a visualized cultural wheel, a set of insight cards, and a series of videos.

The cultural wheel shows the aspects of Table 1 on a large printed sheet of a visualized wheel (See Figure 3). The form of a wheel was chosen to make the information accessible to a design team, and to give each aspect equal weight. The aspect socio-cultural values is positioned in the middle of the wheel because it is the core that binds all other aspects.
The 72 UX insight examples were communicated in the format of cards, since they can be used flexible, spread out, studied individually, placed together, and shared among members in a design team (Beck, Obrist, Bernhaupt, & Tscheligi, 2008). Each example was categorized according to the nine cultural aspects (see the bottom-left corner of the cards in figure 4). Most of the insight cards included raw user experience data such as user quotes, images from the field as suggested by Sleeswijk Visser (2009). The other cards consisted of information from literature and desk research, especially for the aspects socio-cultural values and macro developments. Figures 3 illustrates how the insight cards were presented on the cultural wheel and Figure 4 gives examples of the cards. In addition, four video clips from participants in the data gathering study were selected.

(3) The results of evaluating the toolkit
Generally, all the designers in the sessions considered Cultura as an inspiring toolkit in helping them understand user insights in a different cultural context and lead
towards creative design ideas. Moreover, most designers said the design format of Cultura was inviting and the process was creative. Yet they found it challenging to process all the information thoroughly and generate ideas simultaneously within the limited time. The groups of designers who got sensitized with their own experiences, turned out to have more design ideas (7 and 8), compared with the groups who did not (4 and 6).

In the remainder of this section, we will first discuss our findings on how each tool of the toolkit was used; then we report other issues during the sessions. Our findings are structured based on two main sources: the designers’ reflections on the Cultura toolkit, and the observations during the design sessions.

The use of the tools

Cultural wheel provided designers a clear overview of what aspects can be considered when encountering an unknown cultural context. In the evaluation interview, one designer said the cultural wheel ‘gives a clear overview’. He added, ‘If you have an overview, I think it really helps your design and also speeds up the process, more importantly, coming up with richer ideas.’ These aspects also helped the designers to structure, manage, and keep track of user information. As we observed during the sessions, all the designers used this structure to organize their post-its (notes) and to arrange the filtered insight cards (Figure 5). ‘It helped us to make connections among all the aspects and based on the connections we develop an understanding about their situation,’ explained a designer. Next to that, the designers were asked to reflect on the 9 cultural aspects specifically. Each of the aspects and their related cards were found to contribute to generate an overview of the intended cultural context: ‘The connection between those aspects is really interesting for understanding the situations. I don’t think an individual category will be enough to gain such understanding. I think we used a lot of connections between those.’ This confirmed our confidence in not explicitly providing theory about the connections, but rather evoking them through the format of the toolkit.

More specifically, the aspect Socio-cultural values was used to inform the designers about the main drive for activities that the users do and the reasons why they perform these in a specific way in a cultural context. According to most of the designers, this aspect and the corresponding cards could not inspiring design ideas, but were used to check the values to confirm or to select ideas. The aspects the material world and rituals in every day lives were expected categories: ‘As we are product designers, it’s kind of our nature to be interested about users’ material world and their everyday activities.’ The aspects know the rules, division of roles and community were
relatively new to the designers: ‘Somehow I would consider people’s roles or their community in my normal design process, but not explicitly. So the way it emphasized these aspects was helpful.’ A designer added, ‘The aspect of rules was really new to me, and it triggered us [to have] many ideas.’ The other aspects did not contribute to generating ideas directly, but they supported designers to generate a holistic view on the users’ situation. For example, angels vs. devils helped designers to find out who the users wish to become, so that they could understand what social pressures they were struggling with in their lives. Moreover, some designers found that some aspects of behavior-related insights were missing in the structure of cultural wheel. They observed a number of interactions in the video clips, which they could not assign to any of current cultural aspects, such as expressions and behaviors.

The insight cards and video clips provide static and dynamic ways, respectively, to communicate UX insights. Several designers phrased the benefit of having both as follows: ‘Video gave the realness whereas the cards gave insights,’ in combination ‘the two aspects paint the story in a complete way.’ To be more precise, we found the information conveyed by video clips not only mentioned most of the aspects in the cultural wheel, such as the material world, angels vs. devils, rituals in everyday lives, but also showed the behaviors of the intended users such as the ways of expression, gestures and so on. These behaviors seemed to help the designers feel almost as if they were there. Additionally, it gave the designers a direct impression of the cultural distance between themselves and the intended users. According to a designer: ‘These behaviors (in the videos) are very helpful in understanding the needs of people when facing a new culture.’ Each of the cards consisted of either user quotes or narratives, and a picture from the local context, which gave a more in-depth explanation to what designers sensed from the video. Moreover, the insight cards covered each aspect of the cultural wheel, giving more elaborate information than the video could offer.

The sensitizing workbooks for designers served as the ‘accelerator’ for the design sessions. The designers (in session B) who got the workbooks immersed themselves in the session much faster than those without (in session A). Moreover, the groups in session B had more discussions and ended up with more ideas compared to those in session A. There could be two reasons: one is that the workbook helped them to easily spot differences between their own situation and that of the users; another is that the topics of the excises in the workbook covered many aspects of the cultural wheel, which helped prepare the designers in advance.

Other observations
As expected, the designers’ own memories of student life played a positive role during the sessions. It helped designers gain empathy with the unfamiliar context. By comparing it to their own experience, they could relate the unfamiliar situation to their own context. On the other hand, it helped trigger design ideas. During the sessions we found that designers kept switching viewpoints from an ‘outsider’ to an ‘insider’, and vice versa. In this way, they found many differences and things in common between the familiar and unfamiliar contexts. All the designers considered those very helpful in finding design touch points and triggering discussions. ‘We could not only find similarities and also differences in a short period of time. It really helped to come up with ideas because we got the knowledge,’ confirmed one designer.
In addition, we noticed that most designers were more attached to the differences when generating ideas: ‘I think we did comparison automatically. In the beginning, we wrote down what was surprising to see… and I think the surprising parts were inspiring for coming up with ideas.’ Another team added, ‘I think especially the difference between your own culture and the culture you design for, those are the things that really stand out. You pick them up spontaneously because there’s so much contrast.’ This process made it efficient for designers to learn about the unfamiliar aspects. However, the downside was that they could overlook things many had in common that actually were very meaningful to the intended context. Especially when the difference was too large, designers found it hard to relate to their own experience.

**General Discussion and Conclusion**

This study developed *Cultura* and explored how it can be used as a communication toolkit to augment a cultural basis to the individual user experiences. We summarize the benefits of *Cultura* as follows: *Cultura* categorizes user insights into 9 cultural aspects. It provides a structured cultural basis, which helped designers understand and build connections among the UX information they received. This cultural basis helped to guide designers through the design session, from user insights to the first design idea. In addition, the UX insight examples, after receiving a basis of the broader cultural context, appealed to the designers, and triggered their curiosity. More importantly, the combination of the structured cultural basis and UX insights enabled the designers to think beyond stereotypes. During the interviews we learned that most of them had had more or less stereotyped impressions of the target users in their mind when they entered the sessions. Most of the designers indicated that *Cultura* helped them to broaden their mindset.

The combination of tools enriched the understanding of the intended user/context: video clips brought the narratives to life, whereas the insight cards gave in-depth explanations to the video clips. The cultural wheel served as a primary tool categorizing and communicating the UX insights to the designers. The current format did not emphasise the relationships between cultural aspects explicitly, but it was interesting to observe that the designers started making these connections themselves during the sessions. Moreover, we found that the cultural wheel supported the designers to organize and manage the UX insight cards effectively during the sessions. Inspired by this, we believe there is room to extend this to a research tool, which can serve as a lens for designers to collect relevant data if they conduct user research by themselves. Meanwhile, we also noticed room for improving the divisions of the cultural aspects. For example, some designers observed interesting user behaviors in the video clips, which could not be clustered according to the current cultural aspects. There should be a way to fit these behavioral related aspects to the cultural wheel.

Finally, when developing *Cultura*, we aimed to represent the users and the cultural context as dynamic. We acknowledged the common problem of generalization, which Stake(2000) has addressed, where a small group of people may be erroneously presented or understood as ‘covering all possible variations’. In fact, two designers from the sessions asked to what extent the UX insight examples represent the Chinese students’ lives. This shows the necessity that we need to prevent designers from interpreting *Cultura* (or any user insights) as a statistically, absolutely complete and true representation of a cultural context. Instead, *Cultura* at its best is an authentic
toolkit that invites designers to engage with relevant cultural aspects by giving them both structured cultural basis and UX insights.

*Cultura* worked effectively with design students. To further develop this toolkit to inform design teams about cultural insights, a next step would be to apply the toolkit in the more demanding contexts of commercial design practice. Although we did not test the design ideas coming out of the sessions beyond our own general judgments, this initial study is promising. *Cultura* can be an inspiring motivation for designers, giving them a broader view of the cultural context in order to build an empathic understanding of the intended users, and to make effective designs for people.

**Acknowledgement**
We want to thank the students from Donghua University, Shanghai, for providing user information to this study. Further we want to thank all the designers from TU Delft who took part in the design sessions. The research was made possible through funding (nr.201407720019) from the China Scholarship Council.

Abstract

Case studies are discussed, from Northumbria University’s practice-led Centre for Design Research (CfDR) that demonstrate how visualising concepts and designs through digital animation can enable effective communication of ideas and interactions, which in turn enables creative leaps in thinking, understanding and decision-making. Animation is a tool that can unlock the comprehension into what is and what could be. This paper reflects on a number of collaborative projects between the CfDR and several scientific communities, demonstrating and focusing in particular on the process of visualisation, designing digital animations to communicate complex processes, ideas and interactions. An approach and understanding has been developed about how to effectively communicate potentially complex, scientific and technical concepts for the benefit of the client and the end user, in particular the lay audience whose knowledge of the subject may be limited or non-existing.

Findings indicate that the process of constructing simple digital animated stories becomes a learning process for both designer and client. Critical discussions during collaborative meetings develop shared understandings: helping clients to think more creatively about communication (appreciating the benefits of manipulating a truth to position to waylay contextual confusion), and making implicit knowledge belonging to the client explicit to the designer. It is important to state that this negotiation is more effective when the designer is a layperson with respect to the complex implicit knowledge of the client. During these collaborative conditions the untangling of complex ideas have achieve the a-ha moments in the animations’ audiences.

Keywords: Design, digital animation, communication, technology, complex science, storytelling, Alias Design.

Many new businesses seek the expertise of designers and design consultants to help bring their projects to fruition. Developing technologies, in particular those that have advanced with science have increased both the range and complexity of products entering the market. As designers, we need to deliver a clear understanding of products and the experiences attached to them to potential buyers and users, as well as to inform clients’ decision-making during the developmental process.
It is often the case that mind-boggling technology is contained invisibly within small product enclosures. From both a sales and product development point of view, it is now advantageous to communicate the ‘benefits’ of the product as a *pre-experience*, before the client commits to a decision about its development, or the buyer and user commits to a decision about its purchase. Components of complex technologies may be microscopic, and previously have been depicted by static illustrations, which to a point can explain something of what is happening, but often does not engage effectively with the 4th dimension: *Time*. At best, the changes over time can be

Illustrated through storyboarding, but this often leaves aspects like the character of certain movements poorly communicated, e.g. pace, and acceleration. A critical review of design communication tools suggests that a better means of communicating such new technologies and their subsequent processes is through moving pictures, such as animation. This suggestion supports (Cross, 2006) assertion that designers' methods of visualization are shifting in response to a more visually rich world to include a wider breadth of mediums.

The ability to simulate devices and operational situations through animation enables another level of storytelling, which not only guides audiences through new technology concepts, but also engages them on an *emotional* level. This provides the advantage of bringing product experiences, and even early concepts to life, enabling them to be critically reviewed at much earlier stages in their design evolution than might be the case through physical prototypes. Companies can also begin to educate their potential audience months in advance of anything actually being produced, through animated pre-experiences. (Parkinson, 2014) supports the belief that storytelling has the power to facilitate critical discussion around design concepts in his study of the design pitch.

The same process can be used within the companies, to make sure that everyone involved fully understands what their product experience will entail, and even how their project teams are being integrated. This management function opens up a whole different level of project communication to design teams. Animations can be used to shorten the time to that *a-ha* moment of insight for the entire team and reduce potential for misunderstanding or confusion. (Warburton, 1996) stated that ‘communication is key to the design process in that it acts as a facilitator for the creative act. It is acknowledged that effective decision-making is intrinsic to an effective design process. However, if a design *thought* is inappropriately communicated, then design decisions may be made to the detriment of the future development of that design’. So, it is argued that the development and creation of animations must be managed critically from the outset.

**Technology**

There are many that advocate digital storytelling as an instructional tool within education (Jenkins & Lonsdale, 2007, Signes, 2010, Simondson, 2009). (Signes, 2010) in particular proclaims that digital storytelling can build digital, global and visual literacy. However, it is important to appreciate that the right tools must be used for the right jobs. On occasions, it can be argued that designers have used the latest *bit of kit*, whether software or hardware, just for
the sake of it. (Warburton, 1996) raised the need to question whether ‘it is appropriate to use digital technology to communicate a given design?’, prompting us to question its use.

When it comes to explaining some very complex situations, digital animation may not necessarily be the first choice. For example, a physical prototype simulation may enable more effective understandings through kinaesthetic experiences of touch and play. Nevertheless, animation has become central to many communication opportunities and we now see businesses starting to exploit the capabilities of this technology. Animated communication can range from an assembly sequence for a product with many components to a user experience attached to a product, all of which are becoming more and more commonplace during design development (in the experiences of the authors). In the case of the CfDR, the main choice of animation technology since 1990 has been Alias Design, a decision not based on its ability to produce digital animations, but due to its flexible approach to surface modelling geometric and organic forms. This was of particular importance, as design intent has to be successfully carried through from initial sketches or soft models to the end CAD result. The design team at the CfDR did not want to be hindered by the computer’s surface modelling capabilities, and so the primary concern when choosing software had to take this into account. It is possible that had this not been of primary concern, different software may have been chosen, and possibly software without the ability to create animations. (Loosschilder, 1997) observed ‘in concept testing, CAD offers several advantages over traditional visualization techniques […] it is easier to create concepts that are understood by consumers’. It could therefore, be rationalized that this in part could be due to an ability to create animations.

**Process**

As with so many other consultancies and designers, the CfDR follows a typical Staged and Gated process. Splitting the entire design process into smaller, more manageable sections allowing both the designer(s) and client(s) to absorb and reflect on each stage before agreeing to and progressing onto the next. A similar process is followed when looking at the communication of more complex or underdeveloped concepts. There is however, a need for more emphasis on what we describe as the *front end*. What occurs here is essentially a crash course period to build understanding in order to communicate stories effectively. Before designers can develop solutions, they must define what the problem is, and what it might become if unaddressed. Animation may also help in cases of conceptual visualization, facilitating the consideration of ‘how do designers of new technologies begin when they are unsure of what they are making (the goals), what it should do (its functions), or who will use it? (user profiles),(Carroll, 1995).

The *front end* then requires the development of quick storyboards and sketch illustrations, explaining the step-by-step process that will later be animated (see figures 2, 4, 6, and 7.) This stage is an important part in the communication process, as on many occasions it has encouraged deeper conversation between the client and other members of the team. It is these initial sketch storyboards that become a starting point of negotiation to deliver an accurate depiction and a clear story. This parallels the research of (Lawson, 2006) and (Lloyd, 2000) who discovered that storytelling, taking place during verbal discussions between members of design teams, supported negotiations that ultimately led to shared-understandings. This stage is
often the first time that what they know and understand has been visualized in any way, albeit in simple sketch form. It is then the animator’s job of interpreting and modifying any parts of the storyboard, adapting it in real-time to portray their understanding of their concept. In all these situations the visuals produced are creations of the animator, applying their designer’s imagination, employing an artistic license and drawing on common metaphors to convey the narrative in a more intelligible manner. (Bonnardel, 1999) observed during instances of creativity that ‘when designers had to deal with new problems which required an innovative concept (or solution) they could be inspired by familiar objects’. The very same is true here, since we are designing the unknown. Designers rely on experiences of everyday objects and shapes to inform the development of their sketches, and so give the viewer something tangible to engage with. Since sketching is a very quick process, several iterations can be quickly produced. (Suri, 2008) concluded that ‘evaluative or formative design research is essentially an interactive series of learning loops’. As the animation production process is a much slower and more time-consuming process, not spotting misunderstandings or mistakes before this stage can have severe consequences at the back end: production stage, and beyond. For this reason, the sketches are re-drawn in simple vector line art. Necessary detail is added and emphasis on colour and texture introduced to give the narrative more depth. This line art is then taken into the 3D software to produce the first pass of the animation (wireframes).

Up until this point in the process, all the sketches produced have been 2-Dimensional. Re-creating the sketches in Alias Design enables them to be transformed into 3-Dimensions, giving depth and form. However, with the 4th Dimension at our disposal – Time and movement, the objects themselves can be animated, including the camera, by altering the viewer’s line of sight around the objects. This movement becomes equally, if not more, important to the storytelling.

When working with a client, initial wireframe animations are shown to the wider project community, communicating a first realization of the concept or proposal. This enables the client to engage both rationally and emotionally with the mechanisms and their movements as the benefit-narrative of their intellectual property unfolds in front of them. When the front end has been managed effectively these wireframe animations show the client or project community, in sufficient detail, a preview of the core product experience story, enabling making a decision whether or not to proceed to full animation production. Full production involves the adding of textures, colours, lighting effects, and depth of field to ensure that the images are believable and comprehensible. However, when an animation is serving to explain a point in a technological development, as opposed to a finished product, the animator has to be aware of ‘Truth to Position’, (Hilton, 2002) and its ‘rules for conscious honesty in communications to clients or colleagues.’ This approach involves using rendering techniques that ensure that the viewer appreciates whether they are viewing something that is conceptual or close to production. Otherwise it can contribute to expectation management issues around work still to be completed, and time to market. In a similar way, (Kim, Yoon, Whang, Tversky, & Morrison, 2007), refer to similar situations involving text, all be it from a learning and teaching perspective. They use the term ‘Seductive Details’ to describe interesting elements that aid the learning of written material, but that are actually irrelevant and only make the text more interesting and engaging. (Harp & Mayer, 1997) use the similar term ‘Seductive Illustrations’, to describe the same thing. (Garner, Brown, Sanders, & Menke,
1992) offer a further examination of this phenomenon, communicating a warning that such details can, in some instances, become highly memorable, so much so that they actually disrupt the learning and identification of other more important ideas. It is these ‘Seductive Details’ that need to be carefully addressed, and used wisely to balance the ‘Truth to Position’. Rendering and illustrating in ways that are visually engaging must still convey the initial design intent or message in a clear and honest manor.

**Case Studies**

**Carelink**

The Carelink project, in 1999, (See figure 1.) required the development of a telemetric monitoring device for pacemakers. The client, Medtronic, managed this project by running a number of internal and external project teams, including contributions from IBM, IDEO, and Virdev, to deal with different aspects and components of the product.

![Medtronic Carelink](image)

Figure 1: Medtronic Carelink – 3D rendered image.

An intermediate project review of progress highlighted the opportunity to enhance appreciation of the *big picture* and improve inter-team communication if an animation was commissioned to describe the end product, its stages of assembly, layout, and component detail. The authors used Virdev’s Pro/Engineer data from their design development of the casing, by IGES data transfer, to animate the required sequences using Alias Design, Adobe Photoshop and Adobe Premiere.

It was noted that the animation enabled previously unappreciated factors to become more obvious, including: clearances, e.g. limits to PCB population height; and the distributed assembly stages requirement for easy disassembly and reassembly.

Medtronic reported that not only was the animation very effective in promoting the *big picture* and improving inter-team understanding and communication perspectives, it was found to be an effective motivator for team members. As a result, stills were taken from the
Bio Transformations

The BioTransformations project, in 2006, looked at visualizing their revolutionary process of using light activation cloaking technology to selectively administer treatment within the body. Originally brought to the CfDR as a series of 30+ Microsoft PowerPoint slides. The protein uncloaking process was communicated using simple geometric shapes generated from within Microsoft PowerPoint.

Although the PowerPoint presentation included each key stage of the uncloaking process, an understanding of it was not achieved in persons viewing it for the first time, requiring each slide to be clarified at length. As a result, the client had initially been looking for an improved means of graphically communicating the process. Hewitt advised that a more suitable means of communication would be an animation of the entire protein uncloaking process, using the motion of key biological bodies to show what happens.
The whole process was broken down into several smaller steps, the first being: gaining a full understanding of what was happening through sitting down with the client to define and sketch/note in great detail the uncloaking process. (See figure 2.) This took several iterations due to the need for the client to describe this aspect of human biology in layperson’s terms.

Due to the importance of communicating this fundamental knowledge to a broad audience, Hewitt decided it was necessary to describe the process in such a way that a viewer as layperson could gain clear insight. Hence, the animation was designed to include elements that discernibly described a view from within the body so viewers could both identify and appreciate the context. For example, the introduction of red blood cells to the animation, although superfluous to the process, became intrinsic to the viewer comprehending the environment - a balance between 'Truth to Position' and 'Seductive Details' (see figure 3.) This may be referred to as 'representational familiarization'. The client initially struggled to accept this type of change, with its benefits taking much explaining – with the help of a series of sketch illustrations. It was only when the client saw a preview of the animation as a black and white wireframe that they fully understood and appreciated the benefit of the change in the approach to presentation.

The remaining stage involved rendering the entire process: adding colour, shading and adding depth of field to produce a 60 second animated sequence. The animation was shown by the client at a medical conference where it won the award for best presentation at the show.
Mitochondria

This project, in collaboration with Newcastle University’s Wellcome Trust Centre for Mitochondrial Research, involved explaining the process of transplanting pronuclear material from a fertilized egg containing abnormal mitochondria to one with healthy mitochondria - preventing any genetic disease being passed on from mother to child.

Currently this transplantation process is a lab-based procedure. The animated sequence illustrated the identification of abnormal mitochondria and the removal of DNA material from one egg, transplanting it into a new egg containing healthy mitochondria. It acts as an educational tool to promote the understanding and effects of mitochondrial disease. From initial discussions with experts at Newcastle University, the sequence was storyboarded in sketch form, translating the scientific knowledge into an interpreted piece of communication more accessible by a varied audience. (See figure 4.)

Discussions around these sketches allowed for changes in the sequence to be updated in real-time, making sure that the narrative of the story was accurate for the target audience (scientists in the field of mitochondrial disease, along with patients suffering from the disease and their family members). Due to the vast difference in level of knowledge between these two groups, several iterations of sketch storyboarding were necessary before it was possible to deliver an effective and engaging message.
Through employing a high level of contextual detail in the initial 3D animated models, it was decided a more simplistic approach would effectively focus the viewer on the core points. Too much scientific detail and viewers could be distracted from the sequence being described, so **artistic license** was taken to portray the narrative in a more intelligible manner, eliminating the viewer’s need for a scientific background, (see figure 5). The animation sequence was seen as such a success that several variants were discussed addressing alternative procedures.

**QuantuMDx**

The latest project in the series of animations was in collaboration with QuantuMDx, a young and vibrant medical company, developing a hand-held portable diagnostic unit. They required publicity of their product’s technology allowing for both internal and external communication of its potential.

Owing to the vast complexity in the technology, there was again the necessity for several meetings acting as points of negotiation to deliver an accurate story. However, even after initial sketch storyboarding, (see figure 6.) there was, in this instance, a degree of division between team members as to the correct procedure, and the level of complexity required to communicate the benefits.
This became apparent only after illustrations were presented, as each member considered, from their own perspective that they knew what was happening. Once again, the sketch storyboarding (see figure 7) proved essential to the narrative development; every minute detail was discussed at length. Visuals were created immediately so that each team member could agree designs simultaneously. This real-time synthesis of ideas developed the scripting of the animation, allowing for the inclusion of details that, at first, had been deemed unnecessary. Nevertheless, transferring these sketch storyboards into a wireframe animation identified further comprehension difficulties. These would not necessarily have become apparent without the aid of the animation. Further meetings fine-tuned the story allowing the animation to be fully rendered (see figure 8). A video game camera technique - first person perspective - was used to improve the user’s interpretation of the journey in relation to their surroundings. This produced a larger than life experience, positioning the viewer in the heart of the product. Using visual effects like tone, colour, and depth of field focused the viewer’s attention on key aspects.
so the final result became visual more enlightening.

Figure 8: Quantum Animation. Final Version, DNA entering analysis chamber (ITV.com, 2012).

Discussion

The power of digital animation as a tool for insightful experiences had started to become apparent to Hilton since the early 90’s, through the CfDR’s first major design and animation project for Johnson and Johnson, and viewer responses to the complex mechanics behind a simple packaging solution. Working alongside Hewitt since the late 90’s has enabled joint enquiry into developing approaches for animating insights into complex problems and opportunities, for clients, colleagues, and their product or service users.

(Hilton, 2002) explained, ‘in the absence of actual product or even adequate prototypes, animation is often the most appropriate aid’. In Hewitt’s experience, it was the use of artistic license in the Bio Transformations animation that marked a key turning point in the thinking and use of animations, both from an educational and communicative point of view. However, without the knowledge and benefit of inter-team insights, produced from the Carelink animation, the shift in thinking may never have transpired. This was a result of the conscious act of looking at the whole picture from a more removed point of view, not just responding to a client’s wishes verbatim, that creating an animation facilitated. This observation supports the
idea that design is a social process, where communication (and in particular storytelling) can play a vital role (Lloyd, 2000) and (Carroll, 1995).

The CfDR took a leap of faith in starting to propose alternative perspectives and suggesting additional material to the client’s initial briefings. Clients were often sceptical at first, possibly viewing this as an attempt by the animators to build cost into the project. However, the animator’s conviction that these alternatives would provide more effective ways of communicating the mechanics and processes involved, supported through storyboarding and wireframe previews, succeeded in opening up creative discussion which better informed decision-making, and promotion of the intellectual property. It comes to be appreciated by those involved in this process that creativity and effective decision-making at the front end serves to reduce down line costs.

Since the animator cannot be expected to understand all aspects of science there is often a learning curve associated with the start of a new project. While this might be seen as something of a frustration with some new clients, they soon realize this learning through questioning is crucial to the process of considering the target audience and how best to facilitate moments of insight from them, supporting the assertion of (Parkinson, 2014) that storytelling can stimulate critique that in turn supports the design process.

Through experience, the animators have learned that involving more of the project community in the development process created a better understanding of the whole picture. Each individual had his or her own understanding of the science and its benefits to share and question. The project community’s potential to balance the quantity and quality of information involved also had the benefit of highlighting potential for mis-communication and differences in opinion, which could then be tackled openly in the process, enabling the designer/ animator to extract the key points necessary to convey the required story. Acting as a facilitator between the different team members, the animator sounds out, and visually defines, what people see, think, and do. (Moggridge, 2008) described how ‘design thinking can help with the messy and challenging problems posed by the complexity of design contexts [...] Complex design problems, such as systems or services, will be better tackled by a team of people from varied backgrounds, harnessing intuitive processes, but collaborating so that the output from the shared mind is more productive than the sum of the individual contributors.’ This became true for QuantuMDx, contributing to its successful portrayal of the technology being used.

Nevertheless, even with an effective process, not all components will be straightforward to manage. Finding appropriate ways of enabling clients to make their tacit knowledge explicit is quite a challenge for the animator, so that they may then transpose that insight into an intelligible series of visuals that bind the whole narrative together. Commonly this is dealt with by inviting the client to show us the problem, or process, in the easiest way they can. Basic drama techniques of show and tell, facilitating kinaesthetic learning, can often prove useful, enabling the client(s) and the animator to creatively reach new perspectives on the subject matter.

Another component of this process of animating stories of benefit is critical review. We have to question why we are choosing to design or animate in a particular way. What are the driving
factors? At some level it is in part down to the experience of the animator knowing implicitly that certain things will or will not work. (Suri, 2008) explained this as ‘the Role of Intuition [defined] in innovation projects – particularly those that are more radical in scope – discovery and decision making cannot rely exclusively on analytic process. By definition, as soon as we start to think ahead to future experiences and how people might respond, we begin to draw upon our intuitive and interpretive abilities. We begin to imagine and empathize.’ It is this difficult evolution of the narrative story that draws specifically on the imagination of the animator. Since many of the situations described cannot be seen: the end product, its style and visuals, are at the sole discretion of the designer/Animator, providing further creative value.

Scale and level of reality become a major part of decisions on artistic license. If it is decided to err on the side of accuracy certain elements may actually appear completely out of scale to the preconceptions of lay viewers in relation to other elements involved, possibly making the animation visually awkward and difficult to follow. Deciding to emphasize scale differently, use simplistic form, texture, and colour, may allow the interpretations of animations to flow more freely, looking less cumbersome, and so be read more clearly without needing to hold to scientific accuracy.

**Conclusion**

The lessons that come out of using digital animation as a creative tool for facilitating moments of insight, both in the process of animating, and in the viewing of the animations, build confidence in designer/Animators making explicit the implicit knowledge of the mechanics and processes of new technologies.

It is important to involve the cross-disciplinary experiences within the project community in the creative processes of brief development, and storyboarding, through to review of wireframe previews, and critical review of the messages conveyed by each component of the animation before final production. In this way, it is found, that not only does the production become more effective, it can also develop new levels of understanding and creative thinking between team members, through the stimulation of critique and negotiation between members of the team.

Although this paper has focused upon cases of medical science communication, the principles of: discussion, storyboarding, visualization, and rendering, including concepts of ‘Truth to Position’ and ‘Representational Familiarity’, are considered applicable to all sectors that design engages with.

The designer/Animator needs to ensure that front end investment of time, and expectation management, reduces potential down line costs of mis-communication. The designer/Animator’s approach to open learning through questioning, as a layperson, should be appreciated as crucial to developing an effective story of benefit, to facilitate the desired a-ha moment, aiding the design process.

Author Biography
Ian Balmain Hewitt

Ian Hewitt is an Industrial Designer and a senior lecturer, teaching on the BA(Hons) Design for Industry programme at Northumbria University. With over 18 years practical industrial design experience, his knowledge spans both the public and private sector in both the UK and US. Ian is about to embark on a PhD to explore playfulness as an approach to learning and developing better design practices, influenced by and incorporating visual design communication for future teaching activities.

Dr. David A. Parkinson

David’s experience within the design industry pre-dominantly consists of the management of service and product development projects within the health sector (NHS) and FMCG industry (Unilever). His research focuses on understanding the relationship between design and storytelling. In particular, he relates storytelling approaches designers take during a design pitch to their impact on a client’s ability to: understand, value, and think more critically and holistically about a concept.

Dr. Kevin H. Hilton

Dr. Kev Hilton is now a consultant in Design for Transformational Experiences, having spent much of his career investigating how individuals can develop their innovative thinking in order to improve the way in which they see, think, and do things. This area of study has covered a wide range of subjects from Design Against Crime, and Gender Diversity Communication, to the importance of play in developing new approaches to Computer Aided Design.
Designing Information for Artificial Intelligence: Path Recommendation and User Acceptance in a Virtual Space

Jong Myoung Lee, Samsung SDS, Seoul, Korea, yarosno1@gmail.com
Kyung Hoon Hyun*, Hanyang University, Seoul, Korea, hoonhello@hanyang.ac.kr

Abstract

In this study, the authors propose two information layout strategies (informative layout and decisive layout) that influence the user acceptance rate on recommended information. The informative layout is the degree of descriptions in the recommendation process. The decisive layout is the degree of choices in recommendations. Thus, the objective of the paper is to discover how users’ acceptance of a recommendation changes when the recommendation is displayed in different degrees of informative and decisive layouts. To this end, we have conducted the following tasks: 1) Sophisticated software was created with Javascript to conduct experiments with users online; 2) Experiment subjects (N=247) with various education and demographic levels were recruited; 3) User acceptance rate depending on the information layout strategy was collected; 4) The relationships between information layout strategy and user acceptance of the recommended information were computationally analyzed. The results of the study indicate that the information layout strategy proposed in this research significantly influences user acceptance of the recommended information. Also, this research identified effective combinations of informative and decisive layouts to maximize the user acceptance.

Keywords: Information Layout, Artificial Intelligence, User Acceptance, Virtual Space, Computational Design.

Introduction

Both design academics and professionals have widely investigated the relationships between artificial intelligence (AI) and design. In academia, research has been focused on making the design process more innovative and effective by implementing artificial intelligence in design (Tang et al., 2013; Rodgers et al., 1998; Berger, 1980; Reich et al., 1993). In practice, by collecting, analyzing, and implementing the findings on user behavior, the data-driven nature of artificial intelligence has improved the user experience. One of the most widely known examples is Apple's iOS keypad. The iOS keypads provide informative recommendations to the users. For instance, when the user inputs the text “sch,” the system automatically asks if the user intended to type the word “school.” Furthermore, the system can minimize typos by learning the user’s typing pattern and modifying the range of the input area. Artificial intelligence thus ultimately provides optimized experiences by understanding user needs and wants through determination of user behavior. Global companies such as Samsung started incorporating artificial intelligence into their software solutions to maximize the efficiency and usability for users (Bradshaw, 2017). Watson, for example, studied over 605,000 medical records in 2 million pages of text and it is already
better at diagnosing lung cancer than human doctors (Friedman, 2014). Another trend of artificial intelligence in design is conversational user interfaces such as Chabot and voice recognition. Alexa developed by Amazon uses conversational user experience to communicate with the users and studies their buying patterns to suggest new products to sell (Nunes, 2015). It is clear that artificial intelligence has the ability to come up with informative recommendations to users by continuously studying those users. In this respect, the implementation of artificial intelligence in design can change the conventional process of design both academically and professionally. However, the relationship between the ability to produce recommendations through highly accurate predictions and users’ acceptance of the recommendation is an important issue that needs to be addressed. More specifically, will users accept the recommendation from a computer? If they do, why would they trust and take the suggestions? Lee and See (2004) defined trust as the cognitive process towards an agent that helps to achieve one’s objective in uncertain and vulnerable situations. Regardless of whether the artificial intelligence suggests optimized information, if the users have no relationships with the system, they will likely not trust the information. According to Chau et al. (2000), information has different acceptability to users depending on how it is presented. Designers have the greatest freedom to manipulate how information is displayed. They decide the relevance and significance of the information and structure the information accordingly (Wurman, 1996). By identifying and implementing the effect of information layout, the output from the recommended information can be more acceptable to the users.

In this research, we propose two information layout strategies that influence user acceptance of recommended information: 1) informative layout and 2) decisive layout. Informative layout is the degree of description in the recommendation process. Decisive layout is the number of choices in recommendations. In this study the authors focus on identifying the relationships between information layout strategy and users’ acceptance of recommended information. Thus, the objective of the paper is to discover how users’ acceptance of information changes when the information is displayed in different degrees of informative and decisive layouts. To this end, we have conducted the following tasks: 1) Sophisticated software was created to conduct experiments with users online; 2) Experiment subjects with various education and demographic levels were recruited; 3) user acceptance of information depending on the information layout strategy was collected; and 4) The relationships between information layout strategy and user acceptance of recommended information was analyzed.

**Automated Information and Trust**

Artificial intelligence is everywhere. It is in driving, manufacturing, information retrieval, and even security. Automation offers the potential to collect big data, learn unseen patterns, and provide meaningful information. However, accidents and tragedies related to or caused by automated processes have adversely affected the public’s perception of automation and artificial intelligence. For example, Tesla’s automated driving car crashed and killed the passenger due to its failure to detect a truck against the bright sky (Boudette, 2017). According to Parasuraman and Riley (1997), people relate such negative responses to misuse and disuse of automation. Understanding the cause of how people disuse and misuse the automation is the key to identifying how people reject automation capabilities (Lee and See,
One of the critical elements of information acceptance is trust (Staab et al., 2008). Interestingly, humans show similar human-to-human interaction patterns when they respond to technology (Reeves and Nass, 1996). Trust is a social and psychological concept, but it is an essential element to understanding better human-automation partnerships (Lee and See, 2004). For instance, Lee and See (2004) identified three bases of trust: 1) performance; 2) process; and 3) purpose. The performance shows the historical performance of the automation. Therefore, it is important to show previous results to build trust. The process defines how the automation works. Users tend to trust automation more when they understand how it works. The purpose refers to why the automation was developed. In this case, the operator will trust the automation to achieve the objective. Constant communication of what automation does and how it can benefit the user is an essential element (Lieberman, 2009). Lieberman (2009) argued that artificial intelligence needs to have more tutorials or presentations of its features to introduce its capabilities to users better. The way the information is displayed is one of the essential qualities of trust (Lee and See, 2004). According to Cyr (2008), information design has significant relationships to trust. In other words, depending on how we structure the way information is displayed, people’s trust in the information can vary.

Information Architecture Design

Information Architecture Design is a process that forms and organizes information to provide meaningful insights. Rich and diverse information is useless to the user when not presented in the right way (Kim, 2005). For instance, data can serve as useful elements to extract hidden insights that were not known before because the display of data significantly influences clarity and excellence of thoughts and objectives (Tufte, 1997). However, data alone is not enough for users or customers. It is the designer’s job to make sense of the data and translate it to useful information to users (Cyr, 2008; Shedroff, 1999). For designers, it is critical to understand what information is relevant to users since the manner in which information is presented influences users’ acceptance (Chau et al., 2000). Therefore, restructuring and reorganizing the design layout of information is a critical task conducted by information designers. Horn (1999) described the objectives of information design as follows: “1. to develop documents that are comprehensible, rapidly and accurately retrievable, and easy to translate into effective action; and 2. to design interactions with equipment that are easy, natural and as pleasant as possible.” These objectives suggest that the goal of information design is more efficient and effective communication. By doing so, information design solved many problems in the design of human-computer interfaces including airplane cockpits (Vicente, 2004) and nuclear power plants (Norman, 2013). Thus, the goal of information design is to make information clearer for users (Wurman, 1996). Designers, therefore, try to create diverse information design layouts so users can better understand and accept the information.

Information Layout Strategy in User Experience

Information design influences the clarity and user acceptance of recommended information. However, the current literature on information layout cannot explain what types of information layout influence user acceptance of recommended information. Thus, we propose two information layout types to identify the relationships between user acceptance and
recommended information: informative layout and decisive layout. The definition of the informative layout is the degree of description in the recommendation process. For example, a high informative layout would show information such as estimated arrival time along with the calculation process including gasoline usage, traffic, wind speed, and historic pattern values. On the other hand, a low informative layout would show the estimated arrival time only. Unlike informative layout, the definition of the decisive layout is the number of choices in recommendations. A high decisive layout would show a single most optimized recommendation to the user. The low decisive layout would show possible recommendations. A mixture of both informative and decisive layout is used in the real-life design cases. Apple-IBM’s flight solution is a good example of high informative and high decisive layouts. Apple-IBM created a solution that organizes a pilot’s task before-during-after flight. The solution identifies the most important and critical variables (gasoline, taxi duration, weather) to recommend alternative airports in case of an emergency. As shown in Figure 1-a, it suggests an alternative airport in high decisive recommendations with a high informative layout. Google Map navigation has high informative and low decisive layouts (Figure 1-b). Google Map is widely used around the world to locate or navigate to a place. Google Map navigation shows the estimated time of the path and supporting information such as distance, traffic, and routes. It shows alternative recommendations simultaneously. Football Manager has low informative and high decisive layouts (Figure 1-c). Football Manager is a simulation game that a user plays as a football club coach. The system recommends a new player to recruit without descriptions. It is impossible to understand why the player was recommended, and the system also does not provide alternate recommendations. Interpark Tour is one of the most well-known online travel agencies (Figure 1-d). Interpark Tour has low informative and low decisive layouts. Their numerous product recommendations are based on prices without calculation details such as the number of stops, durations, and baggage allowance. Based on the proposed informative and decisive layouts, this research focuses on identifying the relationships between how information is displayed and user’s acceptance of recommended information.

Methods

To test the relationships between information layout strategy and users’ acceptance of recommended information, we conducted a series of experiments. First, we created software with Javascript to collect user acceptance of recommended information. Second, we created a virtual map to test user navigation patterns (Figure 2). Third, user interaction methods within the virtual map were created. Fourth, a series of experiments including tutorials were designed. Lastly, the collected data was computationally analyzed.

Information Layout Strategy: a) Interpark Tour with low informative and high decisive layouts; b) Football Manager with low informative and high decisive layout; c) Google Map Navigation with high informative and low decisive; d) Apple-IBM flight planner with high informative and high decisive.
Figure 2. The Map for Programmed Path Recommendation System
Experimental Setting

Path Recommendation Software

The experiment platform was programmed with Javascript. The platform simulates the navigation system under uncertain locations. The navigation works in a turn based system where the user can move one cell at a time in eight different directions. The size of the map is 20 by 20 cells allowing rooms for generating alternate path recommendations. The concept of fog was used to visualize uncertainty. Once the off-road car moves a cell, the cells next to the car are discovered. Dijkstra’s Algorithm was used to recommend the most efficient path between node a and node b. It iteratively selects unvisited nodes and calculates the shortest distances to their neighbor (Skiena, 1999). The pseudocode for the algorithm used in this research is as follows:

```
function FindShortestPath(Source S, Destination D, Graph G) {
    Initial Q //Initial Set of Unvisited Node
    Visited S //Visited Node Set
    for each Node V in Graph G {
        Distance[V] = Infinity //initially, distance from source to vertex V is set to infinite
        Previous[V] = Undefined //Previous node in shortest path to reach node V
    }
    Distance[S] = 0 //Distance from Source to Source is 0
    Q.push(V) //push all Node into unvisited set
    while Q.isNotEmpty {
        vertex U = Q.popMinimumDistance() //pop a Node with minimum distance (in 1st loop, source is selected) if U == D {
            Previous[V] = U //If next node is destination, job is done
            return Distance, Previous
        }
        for each neighborNode V of U { //Visit all neighbors of selected
            node alt = Distance[U] + Distance[from U to V] //edge relaxation
            if alt < Distance[V] {
                Distance[V] = alt
                Previous[V] = U
            }
        }
    }
    return Distance, Previous
}
```

The objective of this research is to understand how users’ acceptance of recommended paths differs according to the information layout strategy: 1) informative layout; 2) decisive layout. As shown in Figure 3, the informative layout is defined by the degree of description in the recommendations, and the decisive layout is defined by the number of choices in the recommendations. Thus, a detailed description of the recommendation process is shown in the high informative layout and a limited description is shown in the low informative layout. The most optimized recommendation was presented in the high decisive layout, and multiple
recommendations were presented in the low decisive layout.

Figure 3. Informative and Decisive Information Layout Strategies

The geographical variables were implemented as weighting values in Dijkstra’s algorithm. The fuel efficiency (F) and speed (S) were measured to calculate the efficiency of the path. The geographical variables are weather, temperature, and obstacle information (Figure 4). Also, there are different land types such as grass (F=45mpg, S=40mph), dunes (F=21mpg, S=30mph), swamp (F=28mpg, S=15mph), ice (F=11mpg, S=25mph), water (F=5mpg, S=20mph), and rock (impossible to pass) that adversely impact efficiency in navigation. For example, the moving cost is calculated by 
\[ C = \text{Global Variables} \times \text{Texture on Land Type} \]
The speed is calculated by 
\[ T = \text{Global Variables} \times \text{Speed on Land Type} \]. Therefore, both the algorithm and the human subjects need to carefully consider the geographical variables to identify the most efficient path to a target destination.
Subjects
Experiment subjects were recruited from the Amazon Mechanical Turk. The subjects were United States residents (mean age = 34.834 minimum age = 19; maximum age = 76; median =32). 247 participants were selected for the experiment. There were 139 males and 108 females. The path recommendation software that we developed was linked to the Mechanical Turk so the subjects could participate in the experiment seamlessly. A 7-point Likert scale was used to ask about their “tolerance of artificial intelligence,” “frequent usage of artificial intelligence,” and “degree of understanding of artificial intelligence.” The subjects received payment for their participation, and additional “bonus” payments were given based on their performance.

Experiments
This research consisted of two experiments. The first part of the experiment was conducted on a self-programmed path recommendation system. Subjects were asked to navigate through the assigned destinations on the path recommendation platform that we programmed. To consecutively measure users’ acceptance of the recommendation system, users can move one cell per move. The size of the map is 20 by 20 cells, and the shortest path that a user can get to the destination requires 23 moves (Figure 5). The subjects were randomly assigned to four different groups, and each group was tested in a specific information layout setting: (1) informative low + decisive low; 2) informative low + decisive high; 3) informative high + decisive low; 4) informative high + decisive high). At every move, path recommendations were provided to the subjects according to the information layout strategy, as shown in Figure 3. The user acceptance rate was measured based on the rate of subjects taking the recommendations provided by the system. Before subjects navigated the virtual space, a full map of the space was displayed to the subjects for 0.5 seconds. The purpose of this is to put subjects in an uncertain and vulnerable situation.
The second part of the experiment consists of survey questions in a 7 point Likert scale. The following are some of the questions in the survey: “How accurate do you think the Artificial Intelligence recommendation in this study are?”, “How useful do you think the Artificial Intelligence recommendation in this study is?”, “How reliable do you think the Artificial Intelligence recommendation in this study is?”, “How much are you interested in Artificial Intelligence in general?”, “How reliable is the Artificial Intelligence recommendation system in general?” The subjects then conducted demographic surveys.

**Implementation and Results**

The average number of moves the subject took to reach the target destination was 39.202 moves (average of 2.760 seconds per move). If the subjects took the most efficient path, they were able to get to the destination in 23 moves. Figure 6 shows the users’ acceptance of recommended information by information layout strategy.
To examine how differently people accept or reject recommendations depending on information layouts offered by an AI, we conducted a 2 (informative: high vs. low) x 2 (decisive: high vs. low) analysis of variance (ANOVA). The independent variables were informative layout and decisive layout, dependent variable was user acceptance rate, and an interaction of informative and decisive layout.

A significant main effect of decisive layout was found \( F = 10.316; p < 0.001; \) participants accepted recommendations more when the recommendations were in low decisive layouts. This result is caused because simply more number of recommendations were suggested in low decisive layout condition. Whereas both high and low informative layout and a high decisive layout provide a single recommendation, a low decisive layout particularly provides multiple recommendations. Since the default possibilities of a low decisive layout are higher than other layouts, participants were more willing to accept the recommendations from a low decisive layout. More importantly, a significant interaction of informative and decisive layouts was found \( F = 4.110; p < 0.044; \) table 1. To probe the interaction specifically, we conducted contrast analyses. In the low informative condition, both the low \( (\beta = -0.234, t(243) = -0.671, p = 0.503) \) and high \( (\beta = 0.293, t(243) = 0.815, p = 0.416) \) decisive layouts showed no significant difference with user acceptance. In contrast, users accepted less recommendations in the high decisive layout than the low decisive layout in high informative condition \( (\beta = 0.130, t(243) = 3.815, p < 0.000) \). In addition, this result consistently confirms within high decisive layout conditions. In high decisive condition, users accepted less recommendations in high informative (vs. low informative) layout \( (\beta = 0.077, t(243) = 2.211, p = 0.028) \). The result of the study showed that the user acceptance of recommendation from AI is at its lowest when the recommendation layout is in both high informative and high decisive. We assume that
these results – people tend to accept less recommendation when the recommendation is provided in both high informative and high decisive layouts – were driven by the free will of human beings. Belief in free will provides a feeling of stability and control, and humans have a strong preference for freely choosing (Wertenbroch et al., 2008). In addition to the human free will of choices, if the information of recommendations given by AIs is cognitively demanding to understand, people may resist advice from AIs even more. Similar to choice overload, information overload can lead to negative impact on decision making (Scheibehenne et al., 2010). Therefore, adding a cognitively-demanding aspect of high informative layouts to an absence of choice freedom of high decisive layouts should boost people’s negative reactions toward recommendations, and in turn, decrease user acceptance rates. In sum, the results indicate that to increase the user acceptance of recommendations, AIs need to provide information that is easy to understand and provide more than one recommendations that users can decide in choosing the recommendations.

Conclusion

In this research, the authors proposed a new information layout strategy, informative layout and decisive layout. We identified that the information layout strategy significantly influences user acceptance. Thus, depending on how designers structure the information layout, user acceptance of the recommended information can vary. Also, we identified the most effective combinations of informative and decisive layouts to maximize the user acceptance. However, we showed that the results obtained in this research might vary depending on the domain of application. As a result, we plan to research the proposed methods in different fields such as finance, medicine, and education to increase the applicability of the research. Another important area to investigate in the future is how user acceptance relates to information layout over time. Such investigation can reveal the mechanism underlying how users build trust over the recommended information.

Discourses on Japanese lifestyle in early modern design: A turning point from Westernization to modern design

Yoshimune Ishikawa, Toyo Institute of Art and Design, Tokyo, Japan, yoshimune.ishikawa@gmail.com

Abstract

Low-seated chairs for tatami mats that are characteristic of Japanese-style interior appeared after late 1940s. This article focuses on the ambivalence between Western lifestyles and Japanese lifestyles by tracing the comments of designers, critics, magazines, and so forth to clarify a background of them. The introduction of chairs in Japan was actually involved, by definition, in a dichotomy between sitting on the floor and in chairs, which therefore was far from the domestic practicality of lifestyles among the public. Then we have to observe the two points for the introduction of chairs to break through this rigid situation: (1) how did the public establish definition of chairs outside the Westernization? This article grasps the fact that the artisans and early designers accumulated their experience of producing chairs from scratch, through trial and error. (2) How did the relation between sitting on the floor and in chairs break out of the dichotomy, through ambivalence? This article focuses on the fact that the public enjoyed the physical relaxation offered by the mix of sitting on the floor and in chairs. This constituted the domestic practicality of chairs for the Japanese. Therefore, such experiences of making and using chairs can be summarized as the awakening of a universe in the distance between the floor and the seat-height of Western chairs. It was a new frontier for Japanese designers, and low-seated chairs were born in this space. This article concludes that it marked the transition from Westernization to Japanese modern design.

Keywords: furniture, rhetoric, transculturation, Japan.

Introduction

One might notice a few and rare feature of the modern design of chairs of Japan: the extreme low seat. It was realised through a seat height ranging from 230 to 320 cm. Chairs became popular with the Westernization of lifestyle that had been encouraged by government policy since the late nineteenth century. However the chairs with distinct low seat indicates the salient development as in the process of Westernization.
What did these chairs offer as the value of product? Takesei-isu (Figure 1, Shiodome, 2010) that was designed by Junzo Sakakura (architect, 1901-1969) had no legs. Boards structure supported the back and seat like the blades of ice skates. The most distinct feature is the low seat, which is only 230 mm high. The eye level of someone sitting on Takesei-isu was almost as low as a person sitting on the floor. Although Sakakura did not write any commentary on Takesei-isu, Katsuhei Toyoguchi (product designer, 1905-1991) praised domestic practicality of Takesei-isu in his essay Sakakura-shi dezain no takekagu (The Bamboo Furniture Designed by Mr. Sakakura, 1949): ‘Square weaving, like a traditional rice-washing sieve or fruit basket, is fixed on the wooden frame of the seat. It effectively gives spring of bamboo to the seat…. if accepting such domestic feeing, we can regard it is stronger and more durable than Chikukosha products.’ (Industrial Arts Institute, Ministry of International Trade and Industry, 1949) Chikuko-sha Co. Ltd was a manufacturing company specializing in bamboo. It was famous for Bamboo Chair (1937, Ubunji Kidokoro) inspired from Western modern design such as Aalto’s Paimio Chair. Toyoguchi regarded Takesei-isu as a domestic design, like “a traditional rice-washing sieve or fruit basket,” hereby pointing out the fact that it was characteristic of modern design. Riki Watanage (product designer, 1912-2013) designed Himo-isu (Figure 2) in 1952. The seat and back were made up of ropes; a Japanese zabuton cushion was put on it before sitting. The cushion had traditionally been put on the floor. Watanabe expounded his philosophy of modern design in his essay Kagu to Shitsunai (Furniture and Interior, 1956): ‘Japanese-style furniture had been designed to be placed in a room where we sit on tatami floor mats; therefore, it had a style clearly showing a tradition…If the designer who lives a
modern life designs furniture with clear consciousness of Japanese-style rooms, it will be adequate for the Japanese atmosphere and useful. It will be true modern Japanese-style furniture’ (Katsumi, 1956). He was also aware of domestic design in Himo-isu, expecting “a room where we sit on tatami floor.” Daisaku Cho (product designer, 1921-2014), who worked in Sakakura's office, designed Teiza-isu (Figure 3). The seat was 240 mm high. He wrote, “I designed Teiza-isu to stand in Japanese style room of Koshiro Matsumoto (a kabuki actor)’s house. It was inspired from Mr. Sakakura’s Takesei-isu.” As mentioned above, Sakakura did not write any commentary on Takesei-isu. However his staff, Cho, succeeded his idea with Teiza-isu. Spoke chair (Figure 4), designed by above Toyoguchi, had a simple Windsor back. It had a low (320mm high) and wide seat, allowing one to sit on it with folded legs. He wrote, “my idea regarding living room as a liberal place of recreation and relaxation where we can sit both on the floor and in chairs freely was basically successful.” Toyoguchi seemed to expect the coexistence of both sitting postures.

We can regard the above low-seated chairs as product designs for tatami. However it is difficult to explain their background because of the dichotomy past studies have maintained between sitting on the floor and in chairs.

1. Literature Review: the dichotomy between sitting on the floor and in chairs.

Although chairs were first introduced in the late nineteenth century in Japanese-style rooms along with the tatami in fully Japanese-style houses, the lifestyles of sitting on the floor and in chairs were separate, with each in different rooms. Chairs were found only in a Western living room among Japanese style rooms with tatami in a semi-Western style house. The semi-Western style houses led to the construction of the public-managed condominium called 51C type, which appeared in 1951. It comprised a dining and kitchen in Western style with chairs, and two living rooms in Japanese style with tatami (Sawada, 1995). These were further developed into the LDK type with Western-style living rooms. Thereby, the Japanese style rooms with tatami relatively shrunk against the extension of Western style rooms.

The introduction of chairs has mainly been illustrated as above with the development of houses. However, the relation between sitting on the floor and in chairs is often expressed as a dichotomy. For example, Uzo Nishiyama clarified the dichotomy as three types of lifestyle in Korekara no sumai (Houses of the future, 1947): (1) full Western style with sitting only in chairs, (2) semi-Western style comprising a Japanese-style room with tatami and a Western style room with chairs, and a (3) neutral lifestyle harmoniously including sitting on the floor and in chairs within a room. In a chapter Isu to tatami no kikko (The antagonism between chairs and tatami) (Koizumi, 1979) in her book Kagu to shitsunai-isho no bunka-shi (Cultural history of furniture and interior design, 1979), Kazuko Koizumi pointed out that the introduction of chairs in Japan was an ideological competition between Westernization and Japanese tradition. She agreed to point (3) of Nishiyama’s perspective of chairs placed only in the hall and entrance outside rooms of narrow public houses. Tomoko Sawada described the historical sequence in which public lifestyle developed alternatively with sitting on the floor and in chairs from the 1900s to the 1950s in her book Yuka-za, isu-za (Sitting on the floor and in chairs, 1995). In her article Sho-shigen, sho-enerugi-teki-shiten nivoru “yuka-za” no saihyoka (A reevaluation of “sitting on the floor” from the viewpoint of resource-saving and energy-saving, 2010), Sayoko Matsubara clarified that the lifestyle of sitting on the floor
developed with a growing public awareness of heating efficiency. Kiyoshi Hirai wrote about the 51C type condominium in his book *Nihonjin no sumai to sumai-kata* (Japanese houses and their lifestyle, 2013): “When defining the room-plan based on whether it comprised sitting on the floor or in chairs, it (51C type) had two rooms with tatami, and a dining and kitchen with chairs. Therefore, this was an extension of the previous type of house (semi-Western style)” (Hirai, 2013).

2. Research Method

As mentioned above, we have regarded the introduction of chairs into Japanese lifestyle as dynamic and rational combinations of Western- and Japanese-style rooms in the house plan. However, this perspective was based on a dichotomy between sitting postures. Such a perspective cannot easily lead to the background of low-seated chairs, which were neutral between sitting both on the floor and in chairs. Therefore, we should set aside the definition of this dichotomy to review the introduction of chairs from a public and ordinary point of view.

3. Chairs as ideology

We first focus on how chairs on tatami were discussed as background of low seated-chairs. In reviewing social developments of Westernization in Japan, we realize the fact that chairs were ideological products mainly resulting from the Japanese government’s policies. The new government that was launched in 1868 promoted a policy called *Bunmei Kaika* (Civilization and Enlightenment). The enlightenment in Japan was, in contrast to the Western philosophy of the eighteenth century, etc., a uniform Westernization of politics, industry, the army, and the public’s general lifestyle, including food, clothes, and housing. It is true that the Westernization overwhelmingly prevailed in Japan as later mentioned. It encouraged them to cut off their topknots (1871) and stop wearing swords (1876). The new government implemented telegraph (1870) and postal services (1871), started constructing railway (1872), and adopted the Gregorian calendar (1873) (Jansen, 1996).

3.1. Chairs and tatami in Westernization

Yukichi Fukuzawa (1835-1901), author and teacher, introduced Western lifestyle. He introduced Western lifestyle in his book *Seiyo Isyokujyū* (Western Ways of Living: Food, Clothes, and Houses, 1867) as follows:

The Western house has no tatami. They put rush mats on the wooden floor in the case of simple rooms, or put beautiful carpets down in the case of fashionable homes. Chairs are put out. (Fukuzawa, 1969).

The illustration of the chair in the text has curved legs and back. Slats at the back are boards cut with arcs. This chair is strange, but frankly shows a lack of information on the foreign product. Although Fukuzawa introduced the Western lifestyle with chairs to enlighten society, the public influenced by this enlightenment was often radical. Shuto Yokokawa, a follower of the enlightenment and a doctor who studied modern medical science, rejected tatami in his book *Kaika no Iriguchi* (Entrance of Enlightenment, 1874): ‘We lay down where we walk, arrange
dishes and change baby’s nappy. That’s nonsense’ (Yokokawa, 1993). Eating and sleeping had always taken place on tatami mats using movable furniture and a set of Japanese mattresses and quilts; however, this Japanese lifestyle was denied. Chairs did not only emphasize the superiority of the Western lifestyle over the Japanese one, but they also indicate the fragility of their traditional ethic, which was branded as “nonsense.”

Rokumeikan (1883-1940, Tokyo), designed by English architect Josiah Conder, a foreign advisor hired by the Japanese government, was a Renaissance-style two-story brick residence used to hold parties for foreigners as part of diplomatic courtesy. It featured Western-style chairs that were designed by Japanese artisans. A chair had curved legs and a Gothic-style back with arches and vertical turnings, but the seat was rustic caning (Kuwana, 2012). There were also foreign architects who privately came to Japan to construct Western-style houses in main harbours and cities since the 1880s. Foreign traders, diplomats, and the Japanese upper classes mainly ordered their houses from them. For example, Alexander Nelson Hansell designed Gothic Revival style houses in Kobe, thereby changing the atmosphere of the town (Kamiki, 1993).

Japanese architects who were trained by foreign architects could later design full Western-style residences. However, Japanese architects who learned Western design by watching them also designed residences for the Japanese upper middle classes. They were often semi-Western in style. For example, when Teizo Yanagisawa, a business executive of Nagano prefecture, ordered semi-Western houses from a local unknown architect, he let the architect travel to Tokyo to study Western-style building. The house that was completed in 1888 applied a Western-like carriage- porch entrance and balcony with arched eaves but had a traditional Japanese roof style with gray tile and rooms with tatami mats and fusuma sliding doors (Fujimori & Masuda, 2002). The chairs often stand on the carpets that were put on tatami mats in semi-Western residences.

3.2. Perplexities and Wariness toward the Western Lifestyle

The introduction of chairs were often confronted with Japanese conventional ethics and morality. This contact awakened the public to discreet positions about the both of them, as will be further discussed later.

Some books and newspapers conveyed wariness of the Western lifestyle. The magazine Kaika no Hanashi (Tales of Enlightenment, 1872) criticized the materialistic aspect of Japanese Westernism. The character Fumiaki, who was Westernist influenced by the enlightenment, spitefully says to Ishibe, a samurai: ‘Welcome, Mr. Ishibe. Anyway, please sit down on the chair. You have formal clothing and a bulky sword, so you seem unenlightened’. The samurai says to him with a wry smile: ‘I have heard of your enlightenment for a long time. But first, enlightenment is not easy. Imitating the looks of a foreigner with Western clothing and a hat, having a beard and making your interior white are not regarded as enlightened’ (Tsuji, 1993).

The chairs they sat in seem to be of semi-Western style with turned legs and a lattice back. The immature and strange looks of chairs indicate surface aspects of the Westernization. Here the samurai is not soldier but philosopher. His comment frankly shows the public criticism and wisdom. However, we can find different implications in this satire. One person questions: “you always have the sword. What is the purpose of it?” With this question, the sword turns from a symbol of conventional pride and ethics to just a bold front. The satire does not only
sneer at Western-oriented Fumiaki, but also gives the samurai Ishibe a warning. It reveals that
Westernization and tradition are equivalent in the context of authority. This balance formed
the ambivalence between the Western style and the traditional one. The public would not
expect domestic practicality as public lifestyles in the two styles, both drawn into the
dichotomy.

3.3. Chairs outside of domestic practicality

Therefore, it is a matter of course for Western style furniture to have amusement as an
additional purpose. *Tokyo fuzoku-shi* (Review of Popular Life in Tokyo, 1900) contained
illustrations of pubs where guests seemed to enjoy Western drinks in a casual atmosphere,
sitting on Western peasant-style chairs that was a Western vernacular chair from local areas in
England before the nineteenth century. It had an elaborate carved back and simple legs and seat
(Hirade, 1900). The public was led to enjoy relaxation, recreation, and pastimes. The public
regarded the Western style as exotic. The Japanese was hardly able to use chairs with domestic
practicality. Moreover a semi-Western style also applied Japanese decorations to souvenirs for
foreigners. A furniture merchant Sada Kimura retrospectively noted that chairs were
‘decorated with carvings such as dragons, phoenixes, chrysanthemums and cherry
blossoms…It was strange at a glance but satisfied foreign curiosity and was actively exported
to various countries for a while’ (Tawara, 1966). Exaggerated Japanese decorations were
produced on chairs in Japan for export since the 1880s. It was exported to England, South
America, Germany, Russia, and Sweden, etc., mainly from Yokohama and Kobe, and was
thereby related to Western Orientalism (Yokohamashi Kinro Fukushi Zaidan, 1988). It is true
that financially Japanese merchants benefited from the semi-Western style furniture, but
aesthetically they rejected it.

4. Chairs as direct experience

Then how did the public plan their domestic practicality life with chairs? As mentioned above,
the public would not expect domestic practicality as public lifestyles in the two styles, both
drawn into the dichotomy. Therefore we must first observe how the public established the
definition of chairs outside of Westernization; and then we should focus on how the relation
between sitting on the floor and in chairs broke out of the dichotomy through ambivalence, as
mentioned above.

4.1. The direct experience of chairs by artisans

Unknown artisans independently introduced the chairs into their lifestyle by try and error. For
example, *Nihon-kagu-zuan to seisakuho* (Drawings of Japanese Furniture and Its
Manufacturing Method, 1911) described the fact that artisans should set legs on Japanese
furniture to make Japanese furniture higher in order to fit Western-style rooms with chairs. It
cautioned artisans about disharmony between a Japanese cabinet and Western one —
‘disharmony like a joint made of wood and bamboo’ (Komuro & Miyamoto, 1911). Edward
Sylvester Morse (1838-1925), an American zoologist invited to Japan by the University of
Tokyo, also observed disharmony between the chair and table in his book *Japan, Day by Day*
(1917). He stayed at an inn in Yokohama near Tokyo, where he described: ‘the chair has been
modelled from a tourist’s folding chair, only made rigid. The table is a foot higher than ordinary tables, and the chair is too low, so that my head comes to a convenient level with my plate’ (Morse, 1917). It seems to have been made by an unknown artisan. Would it be difficult for the artisans of the time who had never lived a Western lifestyle to adjust to the height of furniture? As mentioned previously, Yokohama was a well-known area for Western-style furniture manufacturing with a harbour. In its construction, the chair in the figure seems to be based on the traditional folding chair that had been used on tatami. We should regard the above instances as direct experiences of chairs for artisans, gained through trial and error. Chikatada Kurata (product designer, 1895 - 1966) designed chairs as early modern design since 1927. Dining chairs designed by him from 1931 to 1934 had a simple structure: a straight back post, seat frame and back leg jointed as a triangle. It also had a distinct rail at the top of the legs so as not to damage the soft surface of tatami. The woodwork was suited to the Japanese-style interior and seems inspired from above traditional Japanese chair put on tatami. Kurata frankly later stated his ambivalence at an informal gathering in 1946: ‘Although I actually like tatami, we have to stop using tatami to make the room rational, or else we will have to unwillingly accept a dual-style of furniture’ (Kitamura, 1946).

However, this concept of ‘dual-style of furniture’ might actually lead to the background of later low-seated chairs on tatami. Kurata designed compact chair with a rail at the top of the legs and then Joichi Kogure (product designer, a member of the Seikatsu kaizen domei - Association for Life Improvement, 1881-1943) insisted on a rational system of chairs that seems inspired from the Kurata’s compact chair. Cubic stools that could turn into side chairs with a back, armchairs with an armrest, settles or easy chairs due to their combinations. They also had a rail at the top of the legs for tatami. He wrote, ‘If we have such a chair, we don’t need a large settle, easy chair or divan, we can efficiently use a few chairs’ (Kogure, 1930). Kogure realistically offered the compact design to introduce chairs into the little Japanese style room.

4.2. The direct experience of chairs by the public

The public also independently accumulated direct experiences of sitting in chairs. The architect Uzo Nishiyama pointed out that the public middle class was accepting of diversity, sitting both on the floor and in chairs, in his book Korekara no sumai (House of the Future, 1947): ‘I hope for the creation of a neutral and new lifestyle with sitting both on the floor and in chairs…It is suited to our natural features and living conditions’. The illustration ‘Type of new lifestyle (living room)’ clearly showed the liberal sitting style of the public, with various furniture such as Western stools, sofas, carpets and Japanese zabuton (floor cushions) being used (Nishiyama, 1943). In the illustration, eight people relax in a Japanese-style room with tatami. Four of the eight sit around a low table, three sit on the floor, and one sits in a chair. Others lie on the floor, sit facing each other in chairs or stand on the floor. They seem to enjoy the physical relaxation.

We can also see the contemporary relaxation chairs offered to the Japanese in the films of Yasujirō Ozu (1903-63). Ozu’s films show the real life of the public, with people sitting both on the floor and in chairs. There is also the scene where an older sister, wearing a traditional kimono and sitting on the floor with a zabuton, talks with her younger sister who wears
Western clothes and sits in the chair. Their sitting level is different at all, but the film shows consecutive shots that look directly at the faces. This vertical eye contact is also a direct experience of chairs among the public.

4.3. Historical status of low seated chairs

The above experiences of making and using chairs can be summarized as the awakening of a universe in the distance between the floor and the seat-height of Western chairs. That might be the first discovery of Japanese modern design, or a turning point from Westernization to Japanese modern design. I believe contemporary popular cultures will develop this point beyond Ozu’s cinema. Low-seated chairs since the appearance of Takesei-isu were born on the frontier. The comments of designers, which seemed to address traditional Japanese style interiors, strictly speaking, looked to the frontier of Japanese modern design on tatami.

5. Conclusion: The turning point from Westernization to Japanese modern design

The public independently established a definition of chairs through direct experiences of making and using chairs. The first achievement may be summarized as the discovery of a universe in the distance between the tatami mat and the seat height of chairs. Low-seated chairs were born in this frontier space. Because they emphasize historical development from traditional Japanese chairs to modern design on tatami, they raise an objection to the stereotypical understanding of the shift from Westernization to modern Japanese design. Moreover, this article unveils the fact that the Japanese public actively sought to develop their own lifestyle, distinct from the trend towards Westernization and beyond the limits of government policy.

Author Biography

Yoshimune Ishikawa

Ishikawa studied the history of design at Musashino Art University in Tokyo, with support from the Japan Science Society’s Sasagawa Scientific Research Grant, and earned his Ph.D. there in 2005. His research into the rhetorical function of products in human lifestyle, with a focus on Shaker furniture and their texts, led to his doctoral dissertation, in which he presented a unique diagram outline of Shaker concepts. He used furniture archives and three-dimensional computer graphics to analyse product design, and subsequently expanded the perspective to include main movements such as Orientalism, the Arts and Crafts Movement, the Vienna Secession, and Mingei. The results transcended traditional dichotomies such as East/West, crafts/designs, beauty/practicality, tradition/modernity, and use of machines/work by hand. This research has been shared in international conferences, such as the International Association of Societies of Design Research(IASDR, 1st, 4th, 5th) and the International Conferences on Design History and Studies(ICDHS, 8th), and He won the ‘Encouraging Prize of Study about Art from the Kao Foundation for Arts and Sciences’ in 2013.
Storytelling Technique for Building Use-case Scenarios for Design Development

Sukwoo Jang, KAIST, Daejeon, South Korea, samething01@kaist.ac.kr
Ki-young Nam, KAIST, Daejeon, South Korea, knam@kaist.ac.kr

Abstract

Numerous studies have dealt with what kind of value narrative can have for creating a more effective design process. However, there is lack of consideration of storytelling techniques on a stage-by-stage level, where each stage of storytelling technique can draw attention to detailed content for creating use-case scenarios for design development. This research aims to identify the potential implications for design development by using storytelling techniques. For the empirical research, two types of workshops were conducted in order to select the most appropriate storytelling technique for building use-case scenarios, and to determine the relationship between the two methods. Afterwards, co-occurrence analysis was conducted to examine how each step of storytelling technique can help designers develop an enriched content of use-case scenario. Subsequently, the major findings of this research are further discussed, dealing with how each of the storytelling technique steps can help designers to incorporate important issues when building use-case scenarios for design development. These issues are: alternative and competitor’s solution which can aid designers to create better design features; status quo bias of user which can help the designer investigate the occurring reason of the issue; and finally, social/political values of user which have the potential of guiding designers to create strengthened user experience. The results of this research help designers and design researchers concentrate on crucial factors such as the alternative or competitor’s solution, the status quo bias of user, and social/political values of the user when dealing with issues of building use-case scenarios.

Keywords: Storytelling technique; use-case scenario; user insights; design development.

There are researches in the industrial design field that suggest benefits of integrating narrative into the design process by using narrative as a tool to communicate information considering user insight (Grimaldi et al., 2013). However, these researches often focus only on the values of using narrative within the design process, and does not examine storytelling techniques stage by stage in order to develop detailed and specific use-case scenarios for design development.

Use-case scenarios as a design method takes the role of representing envisioned user interactions which are meaningful to the user (Aulet, 2015). As such, use-case scenario is a story structured around the user which supports designers to understand and empathize with users for design development (Grimaldi et al., 2013; Aulet, 2015). Therefore, storytelling techniques can be applied to use-case scenario, due to the fact that narratives function to convey information, evoke reflectivity, and to spark imagination and increase creativity (Grimaldi et al., 2013). Hence, examination of using storytelling technique to build use-case scenarios can help designers who are developing use-case scenarios to gain rich user insight (Aulet, 2015). This research aims to examine the objectives of storytelling technique, and
investigate how these objectives can help build use-case scenarios on a more detailed and holistic level.

In order to achieve the research aim, empirical research of which is consisted of three stages were conducted. The first stage consists of storytelling-selection workshop, where the workshop participants (design process experts of four) grouped the stages of different design methods by its objective, and were able to establish a set of criteria. Then, the participants evaluated the four prominent storytelling techniques by the established criteria and selected the representative storytelling technique.

The second stage of the empirical research, scenario-building workshop, was conducted to identify the relationship between storytelling technique and use-case scenarios. Five separate scenario-building workshops were proceeded with each workshop including four design process experts and one storytelling technique expert. Four out of the five workshops, the design process experts belonged to the academia, for the reason of their proficiency of linking another discipline to the context of design. One out of the five workshops, the design process experts belonged to the industry for reason of gaining further insight on the design process in the perspective of practice.

The third stage of empirical research, qualitative coding analysis, was conducted with the results of scenario-building workshop to identify patterns within qualitative data (Saldaña et al., 2013). Subsequently, co-occurrence analysis, which is the counting of paired data within a collection unit, was carried out (Buzydowski, 2015). Finally, further inquiry of the empirical research data was conducted, in which the data emphasizes on what potential each stage of the representative storytelling technique have for building use-case scenarios for design development.

**Use-case Scenarios and Storytelling Technique within Context of Design Process**

Storytelling and use-case scenarios have many similarities especially from the perspective of an overall process which helps narrow down a broad idea into a specific byproduct. In the case of use-case scenario, a phenomena is defined, which leads to the definition of the target user and design problem (Ambrose et al., 2014; Aulet, 2015). Thereafter, the use-case scenario proceeds to the user confronting the design problem by interacting with a design solution, where user sentiment will also be presented (Aulet, 2015; Martin et al., 2012; Kumar, 2013). Subsequently, the overall change of the user will be shown in the final stage of use-case scenarios which aids designers to create a final design (Martin et al., 2012; Kumar, 2013).

In the case of a storytelling, a writer initiates the process with a broad idea which ignites a story (Brooks, 2011). The idea then becomes a concept which is an evolved idea by asking “what if?” (Brooks, 2011). After the concept, the writer narrows down the idea through the development of a logline or a premise (Snyder, 2005; Truby, 2008; Howard et al., 1995). The logline and premise are single line statements with some event that starts the action, some sense of the protagonist, and outcome of a story (Snyder, 2005; Truby, 2008). These single line statements are the foundations of a whole story. For writers to develop these statements into a plot, there are various step-by-step guidelines or techniques used in practice suggested by the
field experts such as David Howard, John Truby, Blake Snyder, and Christopher Vogler.

For both of these processes, there is one element that plays an important role: the character, or the user. The design process serves the designer to understand the target user with the objective of creating a solution (Ambrose et al., 2014), where the use-case scenario collects intrinsic and extrinsic factors of the user (Aulet, 2015). Likewise, storytelling techniques have the same value to a writer, where the techniques enable the writer to create characters, the story world which surrounds the characters, and the plot (Truby, 2008). Due to the fact that storytelling techniques depend heavily on the character and the journey, moral debate, possible conflict, and the fact that use-case scenario functions to identify user insights, it would be highly relevant to explore and compare storytelling techniques and use-case scenarios for design development based on user insights.

Integration of Narrative and Storytelling in Design Process

Previously, there have been research on integrating narrative into a design process and investigate its influence on design quality. First in Ganoe (1999)’s research, the author derives a new theoretical framework from narrative structure that “establishes specific design criteria applicable to understanding the human experience of interior space” (Ganoe, 1999). The developed framework functions to predict a possible reaction of the space occupiers and assist designers to make concrete decisions. In this work, narrative is used as a tool to assist designers by taking human meaning into consideration. Similarly, there was a study on humanizing design through a narrative inquiry. Here, the narrative inquiry is used as a ‘constructivist learning activity’ where designers are assisted to derive meaning from human experience (Danko, 2006). By integrating narrative inquiry, the authors suggest that a design can be more human-centered. Again, this research uses a concept of narrative as a tool for better understanding of users.

While there are numerous research that attempts to use narrative as a tool during the design process, there is a lack of research that comprehensively defines what narrative means in design. In a recent study by Grimaldi et al. (2013), the research discusses five different definitions of narratives, analyzes the functions of the narrative in design process, and suggests types of narrative to use during particular design processes (Grimaldi et al., 2013). Grimaldi et al. (2013) organizes seven representative functions of narrative and they are (1) conveying information, (2) evoking reflectivity, (3) showing/teaching values, (4) empathy and identification, (5) imagination and creativity, (6) memorability, (7) delighting (Grimaldi et al., 2013). Narratives function to convey information especially for designers and researchers to communicate insights more clearly using persona stories and stories about current product use. In addition, narratives can evoke reflectivity by placing products to a conflict to highlight design problems. Narratives also can be used to show and teach values to the designers, to achieve empathy with real users, to spark imagination and increase creativity, to remember user insights better, and to delight the fellow designers during the design process. Three of the seven functions—1) conveying information, (4) empathy and identification, and (6) memorability—focus on the communication of, empathizing with, and the memorability of user insights during the design process. The element of user insight is considered important because the design process focuses on the user, and what kind of contextual situation the user is placed in (Best, 2010). Likewise, use-case scenarios within the design process assists designers to gain user
insight considering the design problem, user actions, user sentiment, which focuses on the user and user’s interaction with his or her extrinsic factors within a contextual situation. (Ambrose et al., 2014; Martin et al., 2012; Kumar, 2013; Aulet, 2015)

**Types of Story Design Techniques**

All storytelling techniques involve common steps during the initial stage where every story begins with an idea which becomes a concept, and the concept is developed into a logline or a premise (Snyder, 2005; Truby, 2008; Howard et al., 1995; Vogler, 2007). However, it is the process after the logline or a premise called a plot development that differ for various scholars. Four prominent storytelling techniques were selected of which are as followed: 1) Blake Snyder’s *Beat Sheet*, 2) Christopher Vogler’s *Hero’s Journey*, 3) Larry Brooks’ *Story Structure*, and 4) John Truby’s *22 Steps of Story Structure*. These storytelling techniques were selected for the reason of following the ideas of Aristotle’s *narrative theory*, which considers in context both the writer and the narrative’s effect on the audience (Grimaldi et al., 2013).

Blake Snyder’s *Beat Sheet* is composed of 15 beats or elements that compose a screenplay. The first column of Table 1 lists the 15 ‘beats’, where each of the ‘beats’ guides the writer to write one or two sentences explaining the each stage of the plot (Snyder, 2005). The next column, Christopher Vogler’s *Hero’s Journey* is composed of 12 structural elements that are found universally in myths, fairy tales, and movies (Vogler, 2007). The third column, Larry Brooks’ *Story Structure* is composed of four main parts (setup, response, attack, and resolution). Like the *Hero’s Journey*, the four parts are also in the perspective of the protagonist using the terms such as ‘orphan’ and ‘wanderer’ (Brooks, 2011). Lastly, John Truby’s *22 Steps of Story Structure* tackles the structural element from the perspective of the protagonist, the plot, the story world, and the moral argument (Truby, 2008).

### Empirical Identification of Application Condition

The empirical research consists of methods of: selecting the representative storytelling technique, linking the selected storytelling technique to the key factors of use-case scenario, and analyzing the findings concerning the relationship between the technique and factors. With the findings obtained from the empirical research, it was possible to gain insight on each stage of the storytelling technique’s possibility of aiding designers for enhanced understanding and communicating of user needs for building use-case scenarios.

### Representative Storytelling Technique for Building Use-case Scenario

To select the representative storytelling technique for building use-case scenarios, criteria were identified from the storytelling-selection workshop by using the KJ method. The KJ method was selected for this process to meaningfully cluster insights from research (Martin et al., 2012).

Narrative-led design methods were chosen as the source of the selection criteria for the reason that these design methods function as synthetic and analytic techniques, which bring out design deliverables in the same way as use-case scenarios (Aulet, 2015).
The established selection criteria is as follows: contextual situation of user, user actions, user thoughts, and user sentiment. The criteria were also classified into two groups which are the definition group and development group. First, the definition group is of which the user needs and design problem are defined. Second, the solution group is of which starts from the user perceiving the design solution and ends to results due to the interaction between the user and design solution.

The 22 Step Story Structure (Table 2) was selected as the representative storytelling technique. This was due to the fact that the 22 Step Story Structure satisfied both aspects of defining user needs and design problem (definition part) and user-solution interaction (solution part) while addressing the user’s contextual situation, user actions, user thoughts, user sentiment.

| 1. **Self-revelation, need, and desire** | Representing the overall range of change of the protagonist in the story |
| 2. **Ghost and story world** | Everything that has happened to the hero before the story you are telling begins |
| 3. **Weakness and need** | Character flaw / What the protagonist must fulfill in order to have a better life |
| 4. **Inciting event** | An event from the outside that causes the protagonist to come up with a goal and take action |
| 5. **Desire (goal)** | The protagonist’s particular goal |
| 6. **Ally or allies** | The protagonist usually gains one or more allies to help him overcome the opponent and reach the goal |
| 7. **Opponent and/or mystery** | The characters who want to prevent the protagonist from reaching his or her goal |
| 8. **Fake-Ally Opponent** | A character who appears to be an ally of the hero but is actually an opponent or working for the main opponent |
| 9. **First revelation and decision** | The protagonist gets a revelations or reveal, which is a surprising piece of new information |
| 10. **Plan** | A set of guidelines and strategies the hero will use to overcome his opponent and reach the goal |
| 11. **Opponent’s plan and main counterattack** | The opponent comes up with a strategy to get the goal and begins to execute a line of attack against the protagonist |
| 12. **Drive** | The series of actions the hero performs to defeat the opponent and win |
| 13. **Attack by ally** | The ally encouraging the main character to keep on going by telling him or her the hard truth |
| 14. **Apparent defeat** | It seems as if the protagonist believes that all is lost and his opponent has won but the end there is hope |
15. Second revelation and decision
The protagonist gets a new piece of information that shows him or her that victory is still possible

16. Audience revelation
The moment of when the audience learns an important piece of new information

17. Third revelation and decision
New and valuable information revealed to the protagonist, which makes him or her feel stronger and more determined to win

18. Gate, gauntlet, visit to death
The conflict between the protagonist and opponent intensifies and it becomes almost unbearable

19. Battle
The final conflict in which determines who wins the goal

20. Self-revelation
The protagonist learn who he or she truly is

21. Moral decision
The moment when the protagonist chooses between two courses of action, each of which stands for a set of values and a way of living

22. New equilibrium
Once the desire and need have been fulfilled, everything goes back to normal (with the important change of the protagonist)

Potential of Storytelling Technique for Use-case Scenario Development

As the representative storytelling technique was selected, it was possible to proceed research on finding the relationship between storytelling techniques and use-case scenarios. To accomplish this, five separate scenario-building workshops were conducted with each workshop consisting of four design process experts and one storytelling technique expert. The design process experts’ role within the workshop was to examine through discussion of how each stage of the 22 Step Story Structure could be used to build use-case scenarios. The storytelling technique expert had the role of explaining the stages of the selected storytelling technique and guiding the design experts of their interpretation of the storytelling technique based on its correct function.

All of the five workshops concluded with a semi-structured interview session which was organized to identify and define the key factors of use-case scenarios. A total of 14 key factors of use-case scenario was identified of which are: ‘user’s contextual situation’, ‘user needs’, ‘user goal’, ‘social and political values’, ‘problem and opportunity’, ‘user perception’, ‘user interpretation’, ‘user interaction’, ‘status quo’, alternative or competitor’s solution’, ‘designer revelation’, ‘design feature’, ‘design solution’, and ‘changed life’ (Table 3).

<table>
<thead>

<tr>
<td>Social and Political Values</td>
<td>Social and political views of the user which affects the user’s choices.</td>
</tr>
</tbody>
</table>
Problem and Opportunity
The issues concerning user needs and contextual situation. These issues can be also the source of inspiration for possible design solutions.

User Perception
The way user will notice intrinsic and extrinsic factors prior to the interaction of intrinsic and extrinsic factors.

User Interpretation
The way user will understand intrinsic and extrinsic factors during the interaction of the factors.

User Interaction
The way user will communicate with intrinsic and extrinsic factors.

Status Quo
User’s bias / opinion.

Alternative or Competitor’s Solution
Other solutions which serves the needs of the user. Within or out of the design development’s product range.

Designer Revelation
User insight gained by designer.

Design Feature
Important elements of the design.

Solution
Solution of which will satisfy the needs of the user.

Changed Life
User reaching his or her goal due to the interaction with design solution.

With the results of the scenario-building workshop, qualitative coding analysis and co-occurrence analysis drew out the relationship between the key factors of use-case scenario and each stages of the 22 Step Story Structure. Priori coding was supported by the pre-existing stages of 22 Step Story Structure, and the open coding was conducted based on the key factors of the use-case scenarios. The data of the scenario-building workshop were converted into five individual transcripts for each of the five workshops which were conducted. The transcripts were then loaded onto a qualitative data analysis software, Nvivo. The qualitative coding analysis was conducted twice in order to obtain the inter-coder reliability. Two inter-coders participated in this process, where the calculated Kappa coefficient was 0.73737 and the strength of the Kappa coefficient is substantial (Landis, 1974). As the qualitative coding analysis was finalized, co-occurrence analysis was conducted to identify how storytelling techniques can be used by designers to build use-case scenarios which addresses the change that new design can offer to users. With the data gained from the co-occurrence analysis, further inquiry of the transcripts from the scenario-building workshop was conducted. This was done in order to identify the meaning of the connection between the activity codes which are the stages of the 22 Step Story Structure and the key factors of use-case scenario. The results of the co-occurrence analysis is shown in Table 4.

</table>
Out of the overall co-occurrence, three sets of co-occurrences were strongly linked with the research aims to identify the potential of storytelling techniques which helps build use-case scenarios for design development, where major insights were found.

Among 22 co-occurrences, the first major insights were found from the co-occurrence of ‘ally’ of the storytelling technique, 22 Step Story Structure. Ally in the storytelling technique is used as a tool for helping the protagonist reach his or her goal (Truby, 2008). Likewise, ally could be used as a tool for helping the user meeting their needs in the design context. This is because the concept ‘ally’ had strong connections with key factors of use-case scenario: ‘user needs’, ‘design feature’, and ‘solution’. A closer inspection of the scenario-building workshop transcript revealed that ‘ally’ in the design process acted as design features of the solution which fulfilled user needs. For example, a double-sided pen has both fine and medium tips on either end. The tips of different thicknesses will be the user’s ally which helps fulfill the user needs of both note-taking and highlighting lines. Further, an ‘attack by ally’ in the storytelling technique refers to the ally critically urging the protagonist from making unwise choices (Truby, 2008). The concept of attack by ally for the design process can be used to investigate which design features have problems (unwise choices) hence need changes and/or improvement. This is due to the fact that ‘attack by ally’ had strong relation with ‘alternative or competitor’s solution’. From the transcript of the scenario-building workshop, the ‘attack by ally’ in the design process prompted for an alternative solution by revealing ‘unwise choices’. It also referred to competitors’ solution which can be benchmarked for design development. It is important for designers to have insights into the alternative or competitor’s solution. The empirical findings on ‘attack by ally’ in the design process can be supported by Roy et al. (1997) maintaining that a multidimensional approach to design development is needed in order to create a solution which fulfills the user needs, standing a higher chance for a commercial success. For instance, a double-sided pen usually has markings for different thickness with graphics. However, this may not be the best solution. A competitor’s pen may use tapered shapes to indicate different thicknesses. This can be more immediately understood by the user than having to look at graphic markings. The competitor’s design feature offering more intuitive affordance to the user needs to be benchmarked by the designer for a better design (attack by ally).

The second major insights were found from the co-occurrence of ‘Fake-ally Opponent’ from 22 Step Story Structure. For the storytelling technique, fake-ally opponent is a character which seems to be an ally but is actually the opponent of the protagonist (Truby, 2008). Likewise, in the context of design, fake-ally opponent could take the meaning of a point where familiarity seems to be a safe choice but is actually the barrier for users adopting new value. This is due to the fact that fake-ally opponent had strong connections with the key factor of use-case scenario, ‘status quo’. The status quo, is the hardest competitor of all to overcome for users to employ new design due to the users’ tendency of not wanting change within his or her lifestyle (Aulet, 2015; Samuelson et al., 1988). Therefore, fake-ally opponent has a possibility of taking an important role of building use-case scenarios to deal with issues of overcoming natural human and organizational inertia (Aulet, 2015). For example, a private bank wished to achieve higher efficiency in administrating services and lower service prices for their customers. Therefore, the bank wanted to package their customers’ separate services with their customers’ permission. However, it was found that the
customers felt the process of consenting on their newly packaged services cumbersome. The customers knew that they would be offered lower prices for the same services when consenting on the packaged services. However, they had to put additional time and effort into the consent process, they were not eager for change. This phenomena is the customers wanting to remain with the status quo. When this insight was revealed, the bank came up with the solution of automatically changing the customers’ contracts and lowering the costs of the services (Stickdorn & Bisset, 2016). This solution lessened the burden of the users’ decision making process. As such, when considering the users’ tendency of making decisions for building use-case scenarios, it can result in opening up enhanced user-experience of new design value (Aulet, 2015; Samuelson et al., 1988; World Design Organization, 2017).

The third major insights were found from the co-occurrence of ‘Moral Decision’ from 22 Step Story Structure. Moral decision for storytelling techniques is the moment when the protagonist chooses between two courses of action, each of which stands for a set of values and a way of living (Truby, 2008). For the design process, moral decision can be represented by the user’s perception of a design which is affected by the user’s social and political values. This is because moral decisions had a strong connection with the key factors of use-case scenario: ‘user perception’ and ‘social and political values’ in the co-occurrence analysis. It had been discussed in the scenario-building workshop that designers needed to have the understanding of the social and political values of the user in order for design to cater for the different areas foreign to the designer. For example, a nature park will need conservation in order for both the tourist and residents to continuously enjoy the environment. In order to make this possible, eco-tourism needs to be designed and promoted rather than concentrating on profit-making which may lead to harming the environment (Designmatters, 2017). This action may call for moral decisions from all sides including the macro-level business decision and micro-level design decisions. Hence, there is possibility for the moral decision to be used by designers to examine the social and political issues of the user and set a direction on the design solution based on these factors when developing use-case scenarios.

**Conclusion**

The research has identified the relationship between the storytelling technique and use-case scenario. It has also revealed the possibilities of the roles for each step of storytelling technique when developing use-case scenarios for design development. This is deemed a major contribution of the research since the existing literature largely focuses on the meaning of narrative for design, rather than directly linking storytelling techniques in a stage-by-stage perspective in the context of design development. The major findings of the research include: firstly, storytelling techniques can have a meaningful role as constructing guidelines for defining design features and how they could be integrated into user-experience through use-case scenarios. Secondly, the storytelling technique has the potential of helping designers to investigate how status quo can be anticipated in a journey towards developing design solutions. Thirdly, storytelling techniques can offer possibilities of incorporating social and political values of the user in order to create an enhanced user experience while building use-case scenarios. Overall, the storytelling technique has the potential of identifying user-related factors such as user’s status quo and their social/political values as well as design features for offering new design values to target users. The results of this research can be used by designers in practice for building enriched contents of use-case scenarios, while not overlooking crucial factors such as the alternative or competitor’s solution, the status quo bias and
social/political values of the user. The results can also help researchers investigating factors for building use-case scenarios. It is expected that, to gain more insight on the issues which are overlooked when building use-case scenarios through further research.

Author Biography

Sukwoo Jang
Sukwoo Jang, is currently a researcher for Ph.D. in Industrial Design of Korea Advanced Institute of Science and Technology (KAIST) and holds a B.Sc. (2016) in Industrial Design from KAIST. He first became interested in storytelling in the context of design as an undergraduate at KAIST, working on user-experience projects of educational-industrial collaboration to develop user-scenarios for the speculative future. Currently, Sukwoo focuses on incorporating storytelling techniques in the design process in order for users to overcome their status quo bias and embrace new design in digital services.

Ki-young Nam
Dr. Ki-Young NAM is Associate Professor of Industrial Design, KAIST. He received BA (Hons.) and MA degrees in Industrial Design from Central St. Martins College of Art and Design, University of the Arts London. Subsequently, he obtained Ph.D. from Manchester Metropolitan University. Ki-Young worked as Faculty Research Facilitator at University of Lincoln, U.K. before joining KAIST where he established Designize Research Lab and engaged in research on various topics on design strategy and innovation, service design and design for policy. He has since published his research internationally in major design and design management journals and conferences for which he also regularly reviews research papers. Ki-Young also carries out government research and industry projects for major companies such as Samsung, LG and Lotte, and has advised the government in various capacities. He served as Editor-in-Chief for the Journal of Design Management. His current research interest includes design for social innovation and policymaking.
Snack Food Package Design: Exploratory Study on Children’s Snack Choices and Design Elements

Sunghyun R. Kang, Iowa State University, Ames, USA, shrkang@iastate.edu Debra Satterfield, California State University, Long Beach, USA, debra.satterfield@csulb.edu
Nora Ladjahasan, Iowa State University, Ames, USA, nading@iastate.edu

Abstract

Packaging is an essential element of design for both consumers and businesses. Product packaging functions both as a communication tool for product information and for brand messages. In addition, the role of visual elements and messages on snack packages are not well understood. This is particularly true from the standpoint of influencing the selection of snack food in children, even though there has been growth in the economic power of children as a consumer group. Therefore, this study examines: 1) the role of design variables such as typography, images, and the stylistic combination of these visual elements in affecting children’s snack food selection; 2) the role of health messages on children’s snack food selections; and 3) the role of perceived ‘healthiness’ in influencing children’s snack food selections. Digitally-simulated snack package images were created and sixty children ages 9 to 13 were recruited for this study. From these design variables, ‘preferred selections’ and ‘perceived healthy selection’ of children in this age group were identified.

Keywords: Package Design, Children, Design Elements, Healthy Snack Choices, Preferred Snack Choices

Many marketing research studies have been conducted that address the important role that packaging plays at the point of sale (McNeal & Ji, 2003, Silayoi & Speece, 2004, Abdalkrim & Abdulaziz, 2013). These studies have shown how packaging communicates the content of the product and influences a consumer’s buying decision. Food packaging as a form of communication provides an opportunity to connect with the audience and to convey information that persuades a consumer’s food selection (Roberto et al., 2007, Robinson et al., 2010). Because of the growth in the area of children as a consumers group, branding has also been shown to effectively targeted even very young consumers (McNeal and Ji, 2003). Thus, the visual elements of a package are critical in their ability to target both children and adults. They have also been shown to draw attention to the product, create an immediate expectation and generate a sense of importance and trustworthiness in the product. This study builds on earlier work of the authors (Kang et al., 2012, 2016) that focused on the preferred snack selections of children with regard to color and design elements. Additional participants were added to this study and an additional question was added that related to healthier snack choices. This study sought to address the question of which design elements on snack packages promote snack food product selection and how do the health/nutrition education messages affect the selection of snack foods.
The purpose of this second study was to examine the impact of the visual elements on children age 9 to 13 with regard to snack selection and perceived healthfulness. Specifically, this study examines: 1) how design variables such as typography, images, and stylistic combinations of visual elements influence children’s snack food selection; 2) how health messages affect children’s snack food selection; and 3) how perceived ‘healthiness’ influences children’s snack selections. In this study, visual and verbal elements on snack packages were isolated to identify their role in children’s decision-making processes. The results of these studies will be used to create more complex packaging prototypes for further study with regard to healthier snack decision-making.

**Study Design and Methods**

A survey was conducted with digitally-simulated snack package images shown to children ages 9 to 13. The SoyJoy® snack food brand was selected as the model for the packages, but the name of the product was changed to “Enjoy” except for the verbal message test. Soy products are often perceived as a healthy food, but many consumers do not consider soy to have a good taste (Wansink et al., 2000). Therefore, the SoyJoy® brand name was used for the verbal message test to make a connection between a brand and the brand messages. Computer simulations of package designs were presented for evaluation on a 27-inch monitor in a usability lab. The lab for the study was equipped with audio taping capabilities and screen capturing was done using screen capture software for the data analysis. The data was analyzed using SPSS statistical software version 23. The children were divided into three groups. Group 1 was asked in an open-ended manner to select the package with the contents of the snack “they would prefer to eat (PE)” and in a follow up qualitative question they were asked to explain why they would prefer to eat this snack. Group 2 was asked the same question as the Group 1 children and then asked an additional question about which they perceived as a “healthier snack to eat (HE)” based on the package design elements. Group 3 was asked the same questions as those of group 2 but in the reverse order. For group 3, the PE choice was asked first, and the HE questions followed. This study was approved by the Internal Review Board (IRB) at a State University in the USA and a consent letter from parents and an assent form from the children were both required for participation.

**Design of Tested Variables**

Ampuero and Vila (2016) identified the key design elements of packaging as color, typography, shapes, and image. Typography, image, healthy messages, and a combination of image and type were tested in this study. Each category is broken down into five variables, and each variable is designed to identify children’s decision-making factors. Participants picked the background color of the package which they indicated was the color of the package of product that they would most like to eat. Green, yellow, red, pink, and blue were selected from the existing SoyJoy® brand. Green, red, and blue were equally selected by the children in the study as a color they would prefer to eat (Kang et al, 2012, 2016).

**Typographic Variables**
Sans-serif types were used for headlines and titles. Five different type attributes were created to study how typographic variables influenced the decision on the preferred snack and perceived as healthy snacks. Table 2 shows sample designs with different type weights, decorated type with shadow and gradation color, 3D type and undulating type respectively.

Table 1. Type Variables

**Stylistic Combination of Design and Typographic Variables**

A study reported that 69 percent of supermarket food for children in Canada contains a cartoon image or childish typefaces on the front of the box (Elliott, 2012). A set of complex design and typographic variables (Table 3) were created to identify their impact on the children’s decision-making compared to the simple variables shown in table 1 and table 2. Two typefaces and product photos and cartoon images were created to observe the decisions.

Table 3. Combination of Design and Typographic Variables

**Information Verbal Messages**
Table 4 shows the messages that were presented to the participants. The messages in B2 are “Real Fruit, Whole Soy, All Joy,” the message in B3 is “Baked whole soy,” the messages in B4 are “Rich Fiber & Heart Healthy Soy Nutrients,” and the messages in B5 contains all three messages.

</tr>
</tbody>
</table>

**Results and Discussion**

The “preferred snack data to eat” from the group 1 and 2 data (n=40) were not affected by the question related to healthy snack choice. The group 3 data (n=20) were affected by the question related to preferred snack to eat because of the reversed order of questions. The “healthier snack choice to eat” data from group 2 (n=18) was influenced by the “preferred snack data to eat” due to the order of the questions.

**Participants**

A total of sixty children were recruited through email and word of mouth for this study. Table 5 shows the number and gender of the participants in each group. A total 22 children participated in the first group (n=22), the second group (n=18), and a total 20 children, 12 boys, and eight girls, participated in the third group.

<table>

</tbody>
</table>

**Typographic Variables**

Table 6 shows the preferred type choices to eat. The typographic style (T3) with normal weight, drop shadow and color gradation effect in the inside of the letter was selected by 22 children (55%) followed by normal weight with undulating typographic style (T5). The data shows that the order of the questions influenced the children’s choice of preferred snack to eat by the healthier snack choice. The group 3’s “preferred to eat” choice with typography was mixed compared to group 1 and group 2. The reason for selecting the T3 package design for PE varied, but 14 (35%) children out of 40 reported that they responded to the visual elements that grabbed their attention. Table 7 shows the HE selections with the typographic variables.
Children perceived the typographic style with lightweight as a healthy snack for both group 2 and 3. Some children could not make the decision between T1 and T2 in group 2 after the PE question. Children in the group made the healthy snack choice before the preferred snack selection. About half of children perceived the light weight type as a healthier snack choice followed by normal weight type. There were no significant differences between gender and ages.

Image Variables

Table 8 shows that sixty percent of children chose the dynamic line graphics (I1) followed by a photo of realistic ingredients (I3). The reasons for selecting I1 related to its visual attraction. The children described with phrases such as “it is cool,” or “It is eye catching.” The data shows that the participant children in this study were interested in dynamic visual movement. None of the children chose the I2 package, which does not include any illustration or photographs.
Group 2 who answered PE first chose the package with a photo of ingredients and product (I5) as an HE, while Group 3 who answered the HE question first chose the I3 (Table 9) followed by I5. This data shows that when children saw the fresh fruit, they perceived it as a healthier snack than those with graphical images. There gender-related differences when choosing their preferred and healthier snack choice.

Stylistic Combination of Design and Typographic Variables

About twenty-eight percent of children selected stylized text with a simple graphical image (V3) as the PE. A plain text with a cartoon character (V5) was selected as the second ranking, however, the data is not significantly different with regard to the other designs (Table 10). Boys and younger children preferred the package with a cartoon character. The data indicates that the cartoon character was not seen as attractive and it should be reconsidered for future study, while, forty percent of children chose the V3 as the PE after the HE choice. Forty-five percent of children in Group 2 chose plain text with a product photo as an HE followed by V3, while, forty percent of children in Group 3 chose the V3 (Table 11). This data indicates that when a design is simple, children perceived it as a healthier snack.

Information and Messages

About fifty-eight percent of children in Group 2 and 3 chose the package with ingredient information, a health message and a marketing message (B5). Also, forty-five percent of children chose B5 as a snack they would like to eat (Table 12). This data shows that children also read the labels and are seeking information about the product. None of the girls preferred the package with the ingredient information package (B2). Also, the majority of children chose the package with all three pieces of information (B5) as a healthier snack (Table 13).

**Limitation of Study**

This study was conducted in the United States in a largely middle class, Midwestern college town. Therefore, these findings may not adequately represent other demographic groups. Another limitation of this study is that the snack packages were digitally-simulated, this may influence the children’s decision because it didn’t allow for tactile sensations and interaction with the package both of which may affect the decision-making process. Also, the test environment in a laboratory setting could influence children's decision-making processes compared to an actual purchasing environment. In addition, this study was limited to researching only five design variables. This study did not consider the child’s prior experience with this type of snack food or their preferences with regard to snack food types.

**Conclusion and Future Study**

The goal of this study was to analyze which visual elements on snack food packages impact the decision-making process in children ages 9-13. This study found that playful and decorative type styles appealed most to the children when asked to select a snack to eat. The light weight type style was perceived as a healthy snack. The package with a dynamic image followed by with a photo that visually represents its ingredients was selected as a snack that children preferred to eat. When children saw a fresh fruit photo on a snack package, they tended to perceive it as a healthier snack. The packages with a cartoon character and a product photo were not selected as a snack that children preferred to eat. Children tended to consider a snack package with simple and clean visual elements as healthier. This study found that children preferred to read the information on the package when choosing a snack to eat even though the message was given a relatively smaller portion of the packaging real-estate. Also, children considered a package with more information on it as a healthier snack than a package with less information on it. The order of the question related ‘healthiness’ influenced children’s snack selections. The recent research mentioned that “any structured and legible presentation of key nutrient and energy information on the FOP [front of package] label is sufficient to enable consumers to detect a healthier alternative within a food category when provided with foods that have distinctly different levels of healthiness” (Hodgkins et al., 2015, p.1652). Because of the interrelatedness of design variables in the package design, it is important to understand that visual elements that play a dominant role in making the visual and
verbal information clearer and more appealing to consumers. The relationship of design variables on snack package designs should be furthered studied to determine how they impact children’s decision-making with regard to healthier snack choices. The decision-making process is complicated and includes more factors than just visual design variables. Also, children’s behavior within a psychological framework should also be researched to better understand more of the factors that their decision-making process. In addition, design variables are interconnected in the context of a whole design. Therefore, it is critical to synthesize which design elements play a dominant role in affecting the overall perception of a snack food package. Future research will also examine the role of visual design on the decision-making process of adults and other demographic groups.

**Author Biography**

**Sunghyun Ryoo Kang**
She is professor in the Department of Graphic Design at Iowa State University. She received a B.F.A. degree in the field of applied arts from Ewha Womans University in Korea. She earned an M.F.A. degree in graphic communication from the University of Houston and then taught graphic design in Korea for nine years. She earned an M.A. degree in graphic design from Iowa State University and joined the faculty of the Department of Art and Design at Iowa State University in 2000. She has an extensive research and publication background in the areas web design for visual communication and usability, design evaluation, design for diverse users and teaches undergraduate and graduate courses for BFA and MFA programs.

**Nora Ladjahasan**
Nora Ladjahasan is an Assistant Scientist IV at Institute for Design Research & Outreach at Iowa State University (ISU). She is also the CDDIAL program coordinator, a program at ISU Community & Economic Development Extension that works with communities and local organizations/ agencies on economic and social issues utilizing community surveys and other secondary data analysis. She has a PhD candidate in Rural Sociology at ISU and obtained master degrees in Community and Regional Planning at ISU and Bangkok, Thailand. She has conducted several program evaluations in the college, and other faculty/staff evaluations in relation to promotion and other administrative positions. She is currently assisting the College of Design faculty/staff with their researches, and graduate students for their thesis. Her involvement ranges from IRB (Institutional Review Board) applications, development of survey materials, sampling design, data collection techniques, data analysis up to result interpretations. She also gives lectures to research design classes discussing the importance IRB teaches research methodology. She has been working with faculty on their researches doing both qualitative and quantitative data analysis. Faculty researches ranges from issues related to color, autism, student health center design, prison design, snack food packaging design, food experiences, web design and the like.

**Debra Satterfield**
Debra Satterfield, Associate Professor of Design, California State University Long Beach, has extensive research and publication in design for social inclusion, design for behavioral change and the design of educational learning experiences for children with cognitive and physical disabilities. She has published this work through the International Society for Autism Research (INSAR), the Design Research Society (DRS), the International Association of Societies of Design Research (IASDR), and Interaction Design and Children (IDC). She is conducting research on user participatory design for and with children with autism spectrum disorders.
She is also currently researching non-cognitive factors that influence time to graduation for university students and is a researcher on the High Value Degree Initiative, a California state initiative to improve 4-year graduation rates for students at state universities. She teaches in the BA program at CSULB and offers courses in introduction to user experience design and “Research Methods for Inclusive UX Design.”
An IEC 62366-Based Case Study of a User Interface Design Process for a Rehabilitation Device

Abstract

The authors performed a usability improvement study for a shoulder continuous passive motion (CPM) rehabilitation device based on the usability engineering process of IEC 62366, a mandatory standard for the development of medical devices. To enhance the usability of the entire development process for a shoulder CPM device, the authors 1) performed user research to determine design requirements and 2) evaluated the usability of the device. Requirements for a shoulder CPM device were derived through rehabilitation device comparisons, functional analysis, context inquiry and observation, and interviews. The authors used expert reviews and comparison usability evaluation methods for shoulder CPM prototyping. The methods and techniques of these design researches were declared in IEC 62366, but IEC 62366 does not include any guideline in detail. The results of this study can be used to guide the development of a user interface that meets the level of usability standards required for medical devices.

Keywords: IEC 62366, Usability, Usability Engineering Process, User Interface Design, Rehabilitation Device, Shoulder CPM

Literature review

In the version 3 revision of IEC 60601-1, an international standard for electrical devices, usability was introduced as a supplementary standard. The IEC 60601-1-6 specifications describe how to create devices that conform to the IEC 62366 standard. This usability engineering process assesses and mitigates risks caused by usability problems associated with correct use and use errors (Chae, 2015; IEC62366, 2014). According to international standard IEC 62366(2014), use errors caused by inadequate medical device usability have therefore become an increasing cause for concern. Many medical devices developed without applying a usability engineering process are non-intuitive, difficult to learn and use, and cause errors. As healthcare evolves, less skilled users, including patients themselves, are now using medical devices, while medical devices are becoming more complicated. Design of the user interface to achieve adequate usability requires a very different skill set than technical implementation of the interface (IEC62366, 2014).

This study is a follow-up study to ‘A Study on Shoulder CPM Design Guideline Considering Body Size of Korean, (Kweon et al., 2016) and ‘A Study on the Usability Evaluation of Shoulder CPM for Patients Who Need Upper Rehabilitation, (Lee et al., 2017)’. The design process and
improvements in usability were carried out in collaboration with a medical device company and a design specializing company according to the IEC 62366 framework.

**Methods and Scope**

‘Annex D: Guidance on the usability engineering process’ in IEC 62366 includes an overview of usability engineering, a review of the usability engineering process, and associated analysis and design techniques. Figure 1 in Annex D maps the elements in the design cycle based on subclauses of international standard IEC 62366.

Our study to enhance the usability of a shoulder CPM device involved two components: 1) research into user design requirements and 2) usability evaluation of the design. This is the development process corresponding to Figure 1 above. The 'User research/conceptual design' and 'Requirement and criteria development' (gray) in Figure 1 correspond to ‘Research into user design requirements (gray circle) in Figure 2. These elements also correspond to 'Detailed design and specifications' and ‘Evaluation’ (blue) in Figure 1 and 'Usability evaluation of design' (blue circle) in Figure 2.

**Figure 2 : Design process for a shoulder CPM device.**

The authors focused on the usability of engineering process elements related to the desired
characteristics of a shoulder CPM device (work space optimized for three rehabilitation exercises and how to use them at home without specialist help). In this study, the requirements for a shoulder CPM device were derived through rehabilitation device comparison and functional analysis, context inquiry and observation, and interview. The authors used expert reviews and comparison usability evaluations for shoulder CPM device prototyping.

**Research into User Design Requirements corresponding to IEC 62366 –Usability Specification**

In IEC 62366: 2007 + A1: 2014, '5.5 Usability Specification' of 'Usability Engineering Process' specifies the following:

*The usability specification shall describe at least:*  
- Use scenarios related to the primary operating functions, including;  
  - Frequent use scenarios; and  
  - Reasonably foreseeable worst case use scenarios;  
- User interface requirements for the primary operating functions, including those to mitigate risk;  
- Requirements for determining whether primary operating functions are easily recognizable by the user.

‘Requirements by Use Process,’ ‘Work Space,’ and ‘Usage Method’ correspond to the above ‘Usability Specifications.’

**Requirements by Use Process**

The rehabilitation device is a continuous passive motion (CPM) device for the shoulder for patients who have difficulty exercising independently. Repeated and continuous manual exercise conferred by this type of device helps functional recovery. The main application of CPM is to increase joint mobilization and to induce smooth circulation, thereby improving muscle strength (Jeong et al., 2014).

![Figure 3: Actual use of ARTUS-701S](image)

The leading CPM products are the OptiFlex shoulder CPM device, the Kinetec Centura
Anatomical shoulder CPM machine, and the Artromot S3 shoulder CPM device. Eugene Medicare
ARTUS-701S is the dominant product in Korea, and ARTUS-701S and 701ES are used as standard
devices in university general hospitals in Korea(see Figure 3). Four products except ARTUS-
701ES are all-in-one products that attach to a chair. The ARTUS-701ES is a stand-separated
product that is separate from the chair. The CPM’s program supports two or three detailed
movements such as elbow, wrist combined movements in addition to shoulder movements.
To examine the use of upper CPM products in Korea, the authors visited a general hospital of a
national university that uses upper CPM products and a national rehabilitation center that uses
upper extremity rehabilitation robots. Patients were mainly exercised in the order of flexion -
extension, adduction - abduction, horizontal adduction – abduction. In the hospital, CPM devices
were available for both the shoulder and the elbow, but only the shoulder CPM was used because
of the many patients who undergo shoulder surgery. Patients require CPM treatment for 2-3 weeks
or 2-3 months, and devices have to be rented for use at home after hospital discharge. The authors
reasoned that shoulder CPM devices should be able to be used both in the hospital and at home,
and the authors argue that it is necessary to develop middle- and low-cost shoulder CPM devices
that support the three types of exercises that are predominantly used for shoulder treatment (see
Table 1): flexion-extension, adduction-abduction, and horizontal adduction-abduction.

Table 1: Three types of exercises widely used for shoulder treatment.

<table>
<thead>
<tr>
<th>Flexion-extension</th>
<th>Adduction-abduction</th>
<th>Horizontal adduction-abduction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flexion and extension are movements that occur in the sagittal plane. (Muscolino, 2011)</td>
<td>Abduction and adduction are movements that move a structure away from or towards the centre of the body. (Muscolino, 2011)</td>
<td>Horizontal abduction is abduction in the horizontal plane.</td>
</tr>
</tbody>
</table>

Because the shoulder is a sensitive and unstable joint, the shoulder CPM device should have firm
body fixation to maintain a stable posture and take into account natural biomechanics (shoulder,
arm, and wrist movement). In a previous study that investigated shoulder rehabilitation robots, the
existing center of rotation of the shoulder rehabilitation robot was fixed; if the distance between
the rotation center of the product and the center of rotation of the shoulder is not properly corrected
for, shoulder impingement syndrome can occur after treatment (Kim et al., 2013). Therefore, the
development of a shoulder CPM device for hospital and home use should fulfill the following safety criteria: 1) the patient should be able to maintain a stable posture during the exercise and the device should allow shoulder movement; 2) the shoulder CPM device should have a structure and form that take into account a patient's natural biomechanics during exercise, and 3) the shoulder CPM device should facilitate CPM with the correct posture without the help of a specialist. These usability criteria are based on expert reviews of existing products. 1) A shoulder CPM device is required for patients who need to continue shoulder treatment at home. 2) It should be
able to perform three movements: flexion - extension, adduction - abduction, and horizontal adduction - abduction. Natural biomechanics should be incorporated into the device actions when performing these three movements. 3) The user interface should enable the patient to use the device intuitively and stably without the help of a physiotherapist. Unlike other medical devices, rehabilitation devices are less likely to pose a serious danger to users during use, but users are more likely to be ordinary people than experts, so ease of use for novice users is important. Table 2 shows the requirements for a shoulder CPM device derived from analysis of existing products, a field survey, and interviews of experts.

</tbody>
</table>

Table 2 : Requirements for use corresponding to IEC 62366 usability specifications.
Work Space

Existing integral-type domestic shoulder CPM devices are designed to move arms completely forward or laterally (0°). A professor of physical therapy advised that, when exercising the arm, the arm should be able to move to +30° forward and -30° lateral. According to a domestic hospital physiotherapist, detachable-type CPM devices allow adjustment of the angle of the arm during exercise, but the patient can change their body position. Thus, existing Korean shoulder CPM devices have limitations in achieving optimized and stable movement of a user's hands, arms, and shoulders during flexion-extension, adduction-abduction, and horizontal adduction-abduction exercises. To design a shoulder CPM device that overcomes these limitations, the authors considered the user's natural biomechanics (hand, arm, shoulder movement) in the work space. Standard shoulder treatment exercises were recorded by MyoMotion using Noraxon's IMU sensor, as shown in Table 3. The data are reported in 'SizeKorea' which provides Korean body size data, arm length, upper arm length, and shoulder length data from the female 5th to the male 95th percentile of the Korean population (20 - 60 years). A human CAD simulation program and a 3D modeling program were used to simulate the motions associated with the three types of exercises using human body dimension data. Based on the simulation results, the authors derived length, angle, and range data for the hand, arm, and shoulder during these exercises (Kweon et. al., 2016).

<table>
<thead>

<td>Explanation</td>
<td>Record movement of hand, arm, and shoulder during active/passive exercise using MyoMotion.</td>
<td>Human CAD simulation using Korean size data.</td>
<td>Simulation results: Simulation of angles, ranges, and lengths for three different exercises.</td>
</tr>
</tbody>
</table>

Based on the simulation results, a specialist review by a physiotherapy specialist was performed on the developed shoulder CPM prototype. The position, height, and length of the components of the shoulder CPM device that will allow for natural biomechanics are described below. The position of the shoulder CPM body should match the shoulder height of the user so that the user can lean against the CPM body, as shown in Table 4. This will ensure the correct posture and increase stability during exercises. The shoulder axis of the shoulder CPM should match the shoulder axis of the user. In flexion-extension and adduction-abduction exercises, the shoulder axis of the CPM should be located beside and behind the user's shoulders. For horizontal adduction-horizontal abduction exercises, the CPM device should be located above the shoulder.

<table>
<thead>
<tr>
<th>Position of shoulder CPM device body</th>
<th>Height of shoulder CPM device body</th>
</tr>
</thead>
</table>

Table 4: Position and height of the shoulder CPM device's body (Kweon et. al., 2016).
The user should position the arm to be exercised so that the arm and hand are placed on the shoulder CPM device, leaving the arm at +30° from the front and -30° from the side, rather than completely at the front and side (0°), as shown in Table 5. The lower arm of the shoulder CPM device should be able to support the user's arm from underneath so that the user can mount his/her arm. The hand portion of the shoulder CPM device should be able to support the hand so that the user's palm direction is inside the user's body.

Table 5 : Arm and hand rest positions and lengths(Kweon et. al., 2016).

<table>
<thead>
<tr>
<th>Position at rest</th>
<th>Length at rest</th>
</tr>
</thead>
</table>

Usage Method

Consultation with a clinical specialist revealed that it is difficult for the user to assume the correct posture and operate the CPM device if the user has an unstable shoulder. At the hospital, a therapist is present for assistance, while at home, the help of a caregiver is required for correct posture and device settings for CPM device use. Table 6 below shows how to adjust the CPM device to ensure the correct posture and positioning.

Table 6 : How to fit shoulder CPM to user body size.

<table>
<thead>

<th>Adjustment portion</th>
<th>Adjust shoulder left and right positions</th>
<th>Adjust shoulder height</th>
<th>Adjust shoulder and elbow angles</th>
<th>Adjust arm and hand lengths</th>
</tr>
</thead>
</table>
Exercise type, angle, time, and speed of our prototype shoulder CPM device can be set using the remote controller attached to the shoulder CPM device. In a hospital setting, a therapist will often use several exercise settings to accommodate a variety of patients. At home, one exercise setting can be used for the patient. Thus, 12 lists of 12 basic setting values are provided so that the user can select one to start the exercise or change the setting value. The function of the shoulder CPM remote control is shown in Table 7. Functions included in the remote control are based on review of the recommendations of a physical therapist and physical therapy professor.

</tr>
<tr>
<td><strong>Setting the exercises</strong></td>
<td>Provide 12 lists, choose one of the 12 factory defaults to change your workout settings</td>
</tr>
<tr>
<td></td>
<td>1) Selection of exercise type: Front, Side, Horizontal</td>
</tr>
<tr>
<td></td>
<td>2) Choice of exercise time: 1 - 90 minutes, 5 minutes can be selected, the default is 30 minutes</td>
</tr>
<tr>
<td></td>
<td>3) Select the speed of motion: Select 1 - 5 steps, default is 1 step (speed is 40 - 140 degrees per minute)</td>
</tr>
<tr>
<td></td>
<td>4) Minimum angle and waiting time selection: 0 - 180 degrees, 1 - 5 seconds (default value is 0 degrees, change by 5 degrees)</td>
</tr>
<tr>
<td></td>
<td>5) Select the maximum angle and waiting time: 0 - 180 degrees, 1 - 5 seconds (default is 120 degrees, change by 5 degrees)</td>
</tr>
</tbody>
</table>

The remote control, which provides a list of 12 preset values, is efficient in that the user does not have to change the type of exercise, time, speed, angle, and wait time each time they use it. This can be done once the user is in position to exercise; they then select the stored item.

**Usability Evaluation of a Design Corresponding to IEC 62366 – Usability Validation**
This chapter corresponds to the '5.9 Usability Validation' process of IEC 62366: 2007 + A1: 2014, Usability Engineering Process. The final phase of the usability engineering process is usability validation. Usability validation is performed to ensure that the right product is built. Validation is important for the user interface because unexpected interactions between the device and the user might occur that can only be discovered by validation.

User Interface Comparison

Usability evaluation of shoulder CPM devices was conducted using a standard product developed and used in Korea (hereinafter referred to as the E product) and a product developed by a medical device company and design specialization company in this study (hereinafter referred to as the J product). The purpose of the comparability usability evaluation was to investigate the learnability, effectiveness, efficiency, and satisfaction of the user interface of the shoulder CPM device (J product) under development compared with the existing shoulder CPM device (E product). As an off-the-shelf product, ARTUS-701ES, which is used as a standard device in university general hospitals in Korea and has a function similar to that of our device under development, was selected. A comparison of the characteristics of the user interfaces of the two products is provided in Table 8.

<td>- It is possible to set exercise time, angle, speed, load, upper limit standby, and</td>
<td>- Using the remote control, the user can set the exercise mode, time, angle, speed, and</td>
</tr>
</tbody>
</table>
The overall process of use was the same for the two products. However, there were differences in the user interface between the two products with regard to location of the power source, how exercises are set with the remote control (in the E product, settings are changed by touching each item; in the J product, default setting values are selected and changed if desired), and how to adjust the shoulder, arm, and hand positions of the CPM device (E is adjusted by lifting or rotating the fixing part, while J is adjusted by rotating the fixing part).

**Usability Evaluation Plan and Results**

IEC 62366 defines usability as a characteristic of the user interface that establishes effectiveness, efficiency, ease of user learning and user satisfaction. In this study, the authors performed usability evaluation of effectiveness, efficiency, learnability, and satisfaction of shoulder CPM devices based on this definition. A summary of the usability evaluation is provided in Table 9.

There was a statistically significant difference in learning time for the E and J products (p < .05); users learned how to use the J product faster than the E product. The difference in learning time between the two groups is likely due to the learnability of the control method for position, angle, and length in the J product. The E product needed a longer average learning time because the majority of subjects did not intuitively know how to adjust height, length, and angle, and the control method was not consistent. Furthermore, even knowing how to use the product, it was often not possible to produce a smooth adjustment. Therefore, the control method of J product is more intuitive, easy to understand, and consistent than that of the E product.

There was no statistically significant difference in the task success of the two products (p > .05). This suggests that there is no difference in the ability of existing product E and the developed product J to perform their basic functions. This can be interpreted to mean that there is no difference between the two products in basic power on, off, and device adjustment according to body dimensions or change of motion set-up to drive shoulder CPM.
There was also no statistically significant difference in user satisfaction between the two products (p > .05). Subjects were unfamiliar with the rehabilitation equipment that they were using, and neither of the products received high satisfaction scores.

The extent to which error factors affected the performance of the task was assessed. The authors did not set a limit on the number of errors and measured the error level from a low of 0.2 points to a high of 1 point according to Jeon(2011). Table 11 shows the factors that had the highest redundancies among the error factors listed for each product.

Common errors in both E and J products included difficulty in adjusting and manipulating shoulder height. The E product required a lot of power to adjust the shoulder height. The J product required that the shoulder position be ascertained while the operating part was positioned behind the device, and that the shoulder height be adjusted when in a standing position.

Table 11: List of two product use error factors * Low: 0.2 points to high: 1 point.

</tr>
</tbody>
</table>

For the J product, it was difficult to judge the proper posture and settings for treatment, and the inconvenience of the upper arm/lower arm fixing device had reported. In the case of the J product, length and angle should be adjusted freely, not on a step-wise basis. This is difficult for novice users who do not have enough information about suitable positions for treatment; setting the correct value is therefore difficult. In the case of product E, the value can be set within a range as shown in steps 3 and 4. This appeared to be easier for novice users. However, to satisfy both novice users and professional users who might require a more nuanced configuration, the set-value step should be taken into account. Furthermore, for the J product, to adjust the lengths of the upper and lower arms, two pipes must be fixed by turning them. Several users found that this was inconvenient because fixation between the two pipes was not ensured.

For the E product, interference with the device’s work space by the chair and an inconvenient elbow angle adjustment method caused many errors. For the elbow angle adjustment, difficulty was encountered because users were not familiar with how to lift the adjustment device. Finer angle adjustment is also required; the adjustable elbow angle did not provide the proper angle for treatment.

**Conclusions**

This study used the usability engineering process of IEC 62366 to evaluate the usability of a prototype shoulder CPM device. The authors found that the usability of the developed product was better or equivalent as that of a commercially-available standard product. Our study findings and recommendations can be summarized as follows.
The authors developed a shoulder CPM device by collaboration with a medical device company, design company, and university. In general, the level of usability of an end product relies on all parties involved in development recognizing the importance of usability. Based on the usability engineering process in IEC 62366, the importance of usability should be kept in mind throughout the whole development process, from planning to design and manufacturing.

The authors defined the workspace as a design study method, which is not mentioned in IEC 62366. Through this process, the authors were able to optimize the device to perform rehabilitation exercises. There were fewer errors associated with the severity (frequency of reporting and severity score) of interference with the device’s work space and chair during exercise after using optimized exercise settings for the prototype product than the reference product. This means that the designer must consider the context of use based on the use scenarios.

In addition, because the prototype product is designed to be used both in a clinical setting and at home, users will range from experts users to novice. Medical devices are usually used by medical personnel, but this product can be used by the general public who do not have rehabilitation knowledge. Therefore, consideration of use by novices is an important for user interface design. It is also important that the device is able to be operated quickly and accurately, but it is critical that the user interface is designed using easy-to-understand terminology that it is intuitive to use with a consistent operation method. Also, the device should be adjustable without the much power.

In IEC 62366 declare the methods and process of design researches for enhancing usability related safety. But IEC 62366 does not include guideline in detail for designer and design researcher. Therefore this study can be used as an example to guide for development of medical device, especially rehabilitation device.

Author Biography
Agnes Jihae Kim

Agnes Jihae Kim is a second-year Ph.D. student with particular interests in usability, user interface design of products for people with physical disability. She is supported by Global Ph.D. Fellowship from NRF(National Research Foundation of Korea) Grant funded by the Korean Government. She holds a Masters degree in industrial design from Yonsei University(2016), Bachelor of Science degree in industrial design and Bachelor of Interdisciplinary Studies degree in interdisciplinary major of cognitive science from Yonsei University(2014).

Prof. O Seong Kweon

O Seong Kweon is a professor and Head of design and arts at Yonsei University in Korea. He received his Bachelor of Science degree in Industrial Engineering from Hanyang University (1988) in Korea and his Master (1992) and Ph.D. (1994) in Ergonomics from University of Oklahoma, USA. He worked at the LG Electronics Engineering Institute and the Design Research Center, and was the Director of human interface group of the mobile phone division. His research interests are ergonomics, user interface, and universal design.

Prof. Byeong-Jong Lee

Lee, Byeong-Jong is a professor at division of design and art, Yonsei University. He received his Bachelor of Science degree in Mechanical Design from Seoul National University (1988) and his Diplom-Designer from Hochschule fuer Bildende Kuenste(HBK) Braunschweig (1995). Since 1996 he had worked as a professor at Korean Advanced Institute of Science and Technology(KAIST). Since 2003 he has set up a department of Industrial Design at Yonsei University. His research interests are Design Engineering, Social Design and Design History.
Group Storymaking: Understanding an Unfamiliar Target Group through Participatory Storytelling

Abstract

Based on a sound research plan, qualitative user data help designers understand needs, behaviors, and frustrations of a target user group. However, when a design team attempts to design for unfamiliar target groups, it is extremely difficult to accurately observe and understand them by simply using traditional research methods such as interviews and observation. As a result, the quality of user research data can be called into a question, which leads to unsatisfying design solutions. Inspired by a fiction writer’s technique of generating stories together with readers, we present the new method, Group Storymaking, that supports designers to quickly gain broad and clear understanding of an unfamiliar target group throughout a story-making activity with actual users. We envision Group Storymaking as a new user study method that designers can easily implement to learn about an unfamiliar target, involving actual users in a research process with less time and cost commitment.

Keywords: User-centered design; user research; participatory design; storytelling; unfamiliar target users.

User research is regarded as a crucial stage in a user-centered design process. In order to design a new product or system that matches user needs, designers must deeply understand users’ behaviors, goals and frustrations first. However, problems arise when an unfamiliar target group becomes a research subject. The quality of user research data much depends on researchers’ competence in proper planning and conducting the research, and even a skillful researcher struggles with an unfamiliar target. When designers participate in a project which deals with little known target users, it can be a challenge to understand and empathize with those users (Sleger, 2010). In some cases, even user research itself is not allowed, which makes the research far more difficult (Eriksson, 2013).

For example, when young designers work on a project titled ‘developing a new wearable device concept for senior office workers,’ they need to find out lifestyle, interests, needs and current frustrations of the senior target group. However, when they try to conduct user research using traditional methods such as interview and observation, they will face the following problems:

- Their project time and budget are limited; therefore, they need to finish their user research using a few possible research methods within a fixed time period;
- It is difficult to think outside the box, avoid young people’s stereotypes of the senior and elicit creative answers from the target group;
• Since ‘the senior office workers’ are too broad and abstract, it is difficult to narrow down and categorize detailed user types among them;
• Even though designers have developed design scenarios and personas based on user research data, they cannot deeply empathize with the unfamiliar target group, which makes the persona and scenarios lose value.

As shown in the hypothetical case above, the quality of user research data can often be called into a question when designers attempt to design for a little-known target group. Design solutions that lack tangible understanding of target groups are mostly unsatisfying or even damaging to users (Keinonen, 2008).

As a solution to this problem, we propose a novel, easily implementable design method called Group Storymaking based on a fiction writer’s technique (Card, 2010). Fiction writers excel at eliciting interesting, believable episodes of unfamiliar situations and characters. Fictional stories and characters are described so vividly and concretely that readers are captivated and feel empathy with those imaginative anecdotes and creatures. Those stories and characters are not real, but realistic. As design scenarios and personas have a metaphorical matching with fictional stories and characters (Nielsen, 2002; Quesenbery, 2006), how fiction writers create stories and characters became the motif for our research. In this work, we aim to explore the strengths and distinctions of the Group Storymaking method and examine whether the new method can provide designers with representative, trustworthy and insightful user information that broadens their understanding of an unfamiliar target group.

Background and Related Works

Many researchers, designers and developers have reported difficulties in conducting user research on an unfamiliar target group. Antle (2006) discussed problems associated with defining child-users due to limited access to children and designers’ self-referential, distorted preconceptions about children. Slegers et al. (2010) and Duysburgh et al. (2012) pointed out difficulties in using traditionally used research methods for the disabled such as hearing impaired children. Campbell (2013) described various challenges in designing for the inaccessible developing world. Dee and Hanson (2016) argued that recruiting and communicating with the elderly or ‘vulnerable’ people are often a demanding task for designers. These studies emphasize that using commonly used research methods, such as interviews and observation, to research on unfamiliar target groups can be challenging. Instead, designers should devise different research methods that enable in-depth understanding of target groups that are especially unfamiliar to them. The Cultural Probes method (Gaver et al., 1999) is a classic example of a newly proposed user research method based on the motivation to design for the elders.

Information gained from such ethnographic user research is often embodied as a design persona, or “hypothetical archetypes of real users” as Alan Cooper describes (2015). Based on well-planned, in-depth research data, personas work as a human reference by guiding designers to build a tangible representation of target users, to facilitate the communication of information about the targets among team members, and to build empathy for the targets (Cooper, 2015). However, Chang et al. (2008) portray that when a target group is hard to understand and research on, designers in practice use not only data from qualitative user research but also their own
assumptions and experiences in the process of making personas. Pruitt and Adlin (2006) argue that this kind of practice may lower the value of personas as they do not properly reflect real users and are not deemed credible. To address such a credibility issue, past studies have attempted to combine participatory design with a persona to acquire insightful user research data and a reliable persona. Nielsen (2012) involved potential users in two design workshops that took advantage of personas and scenarios to help users come up with future solution. Van Doorn et al. (2013) conducted a case study where children performed as research collaborators to interview their peers or grandparents, gain user information and fill in given templates to create personas by themselves. Dodge et al. (2017) derived 4 persona skeletons from the results of participatory design workshops where users designed eco-feedback technology for their own homes. Nevertheless, these works do not put stress on a specific situation where researchers are faced with little-known target users. Applying participatory design to studying and creating personas of unfamiliar users is expected to be advantageous, as treating potential users as partners (Sanders & Stappers, 2008) can benefit designers and users by facilitating learning about each other (Roberston & Simonson, 2012). The designers can access the users’ tacit knowledge and real stories that are hardly gained when users are viewed as research object. The users can learn about technologies from the designers and create a shared problem space between the designers and them, thereby offering creative insights which the designers might overlook from traditional interview or observation methods.

Based on this notion, this paper presents a new user research method that facilitates understanding of an unfamiliar target through participatory storytelling. When designers attempt to use commonly used research methods for a little-known target group, they often have difficulties in making user research plans and figuring out what type of information they should collect. As a solution to this, our new method gathers rich firsthand user data with unfamiliar target users by letting them collect and classify useful information about themselves, not from them as most traditional user research methods do. Since target users are the ‘experts’ of their own experiences, they are better at providing their data than designers who barely know about them. We also combined a storytelling technique with our method to assist users in telling their stories in an easy, natural way. Besides, empathy is a key in understanding unfamiliar target groups as literatures portrayed (Koskinen, 2003; Lewis & Coles-Kemp, 2014), but designers tend to fail to achieve it using traditional research methods unless they are highly experienced in conducting serious user studies. Our new method is expected to foster designer’s empathy for a target group through storytelling even if s/he is not skillful at user research.

Developing the Group Storymaking Method

Motif for the Method

Group Storymaking is inspired by a renowned fiction writer Orson Scott Card’s ideation technique called ‘A Thousand Ideas in an Hour’ (Card, 2010). It is a story building workshop that involves readers to complete a short story within an hour. The writer begins with any sentence that s/he likes and keeps asking the audience what will happen next, which ends up with forming well-organized, interesting storylines and characters as in Figure 1.
A designer participating in a Group Storymaking process is like a writer in ‘A Thousand Ideas in an Hour’ workshop. A designer generates a character and his/her stories together with a group of people. Starting with a simple question and continuing to ask cause and result questions to actual target users, the designer ‘fleshes out’ characters and scenarios using firsthand experiences of users. Also, low accessibility is a problematic issue in designing for an unfamiliar target group. To address this, Group Storymaking is processed online in order to help designers access people located in remote places as well as to support real-time communication and active interaction among those people and designers.

In Group Storymaking, a character is as much important as episodes. An alive, round character created from Group Storymaking is full of insightful attributes of potential users since that character is grounded on users’ experiences and opinions. Such a well-made character can help designers better understand an unfamiliar target group. Besides, by having a main character in a story, non-designer respondents can participate in Group Storymaking more actively as they can empathize with the character that resembles them and better imagine how that character will behave. To support designers in construction of a character in Group Storymaking, we revised Scott Card’s ‘10 components of a character’ guideline: 1) actions; 2) motivation; 3) past experience; 4) reputation; 5) stereotypes on occupation, gender, age, family role, racial characteristics, and ethnographic nature; 6) relationship with other characters; 7) habits and
behavior patterns; 8) talent and ability; 9) preferences; and 10) physical characteristics (Card, 2010). We assumed that ‘1) actions’ belongs to ‘7) habits and behavior pattern’ as they both referred to the concept of behavior and that ‘10) physical characteristics’ belongs to ‘5) racial characteristics and ethnographic nature’ as the latter includes descriptions of physical appearances. During the Group Storymaking process, designers keep asking questions until enough information about these 8 components is collected to build a vivid character.

Developing the Group Storymaking Guidelines

To develop detailed guidelines for the Group Storymaking method and evaluate its effectiveness, a three-phase study was conducted. In Phase 1, we compared an online 1:1 interview and an online group interview. A designer was recruited and asked to conduct one unstructured online 1:1 interview and one online group chat interview with the same design theme using Kakaotalk, the most widely used instant messenger in Korea, in order to examine the potential of our idea. It was discovered that the online group chat where the respondents were allowed to stimulate each other generated more insightful responses and helped the designer better understand the target.

In Phase 2, multiple online group chats were conducted to establish detailed guidelines for the new method. In this phase, story-making chats were conducted where we generated stories following the method used in ‘A Thousand Ideas in an Hour’. Different groups of potential target users for ten design themes were recruited with whom we conducted ten group story-making chats and created personas. Analyzing their contents, we highlighted special issues that occurred, questioning strategies, and key Q&A parts that led to design insights and important information about the target groups. Findings revealed that it was important to first establish a character’s basic bio profile before generating his/her stories, to illustrate the character’s day from morning till night and to ask questions especially on the character’s needs and frustrations as these might not appear in the previous responses. These key points were developed as the guidelines for the Group Storymaking method. To begin with, the designer gives a name and an age to a character by asking ‘What will be this character’s name and age?’ to the respondents. Next, the designer asks questions about character’s basic bio profiles, which will act as common ground for the respondents in the next steps. Then, the designer asks how the character spends a day in order to let the respondents chronologically describe a day of the character and various episodes that may happen in that day. Finally, the designer asks questions, if necessary, about the frustrations of the character or any more information that s/he has to know.

In Phase 3, two designers were recruited and asked to conduct two Group Storymaking activities with the same design theme on two different channels: Kakaotalk and Facebook Group. The Group Storymaking activity using Kakaotalk was successfully implemented, but the other one using the Facebook Group page failed in receiving enough useful responses. We found it was important to make sure all respondents were participating real-time with full concentration. As a result, the most suitable platform for our new method turned out to be an online instant messenger which supports anonymous chatting. In our guidelines, we suggest using an anonymous chat room in Kakaotalk. Kakaotalk is the most popular instant messaging application in Korea that supports anonymous group chatting in both mobile and PC environments. It is a suitable platform for conducting out method as it allows for quick and easy recruitment of diverse, remote respondents. After creating an anonymous chat room, the designer sends the hyperlinks of the chat rooms to the respondents that s/he has recruited, and asks various
questions based on the Group Storymaking guidelines.

Figure 2 depicts the overall process of Group Storymaking, and Figure 3 shows the detailed guidelines for Group Storymaking that we developed through the above three-phase studies. In Figure 3, the left part describes the steps of Group Storymaking. A designer begins with an introduction and goes through each step to complete the entire Group Storymaking process, where the designer determines basic biographic information of a character to form common ground identity (name, age, gender, etc.), depicts a day of the character to probe its behaviors, perceptions and wishes, and asks additional questions related to the character’s frustrations or needs to elaborate persona description. The boxes on the right of the guidelines in Figure 3 work as tips for designers. As most designers are hardly aware of the 8 components of a character, we provided the list on the guidelines. To help designers better elicit useful responses, we also present some questioning strategies such as ‘Keep asking what will happen next’ or ‘Calling a character’s name instead of saying this character helps respondents to feel empathy and participate actively.’

If the designer thinks s/he has collected enough information on ‘the 8 components of a character’ given in the guidelines, s/he can stop the stork-making activity. The responses can directly be ‘copy-and-pasted’ as persona details without extra analysis.
Examining the Group Storymaking Method

Based on these guidelines, a study was conducted to explore how Group Storymaking works and what pros and cons it has by comparing Group Storymaking with one of the most popular, commonly used traditional user study method in a user-centered design process, 1:1 face-to-face interview. To facilitate comparison, we examined design personas made from the results of each method as they are tangible representations of what has been achieved by each method.

The study was set up as Table 1. We recruited 8 designer students who already had experience in conducting user research as well as using personas and scenarios in a design process. Design students were considered to be more proper participants for our study, as professional designers with rich experiences might not be highly susceptible to minor problems that could occur in a design process, which would make it difficult to examine the effectiveness and distinctions of our method. Design students or design novices, however, usually lack experience in user research compared to professional designers. Therefore, the fact that even such design students can successfully grasp unfamiliar target groups using Group Storymaking would mirror the effectiveness of the method.

To begin with, we showed the participants several examples of design themes and target groups, and asked each of them to select one unfamiliar theme and target among those given examples. We then asked each participant to implement 1:1 face-to-face interviews and Group Storymaking so that s/he can compare both experiences. To compensate possible learning effect, we equally randomized the order of implementation of the two methods; 4 participants (P1, P2, P5, P6) conducted first 1:1 interviews and then Group Storymaking, while for the other 4 participants (P3, P4, P7, P8) the order was inverse. Prior to the beginning we asked all the participants to first
write down questions for 1:1 interviews in order to avoid interview questions being influenced by the result of Group Storymaking. Also, one method should be completely finished before conducting the other one in order to prevent the former from affecting the latter. For example, we did not allow the participants to first interview a couple of people, conduct Group Storymaking in the middle and come back to conduct a few more interviews.

</table>

Before beginning, we provided the participants with our Group Storymaking guidelines and a commonly used persona template with blank spaces for basic bio, behavior, needs and frustrations. However, if those who had to conduct interviews first were already aware of the guidelines, the interview questions might be affected by them. Therefore, we provided those four participants (P1, P2, P5, P6) with our guidelines after they finished interviews.

As for interviews, each participant implemented 3-4 individual face-to-face interviews with 3-4 different interviewees. The participants could only use the interview questions that they had listed at the beginning, but they were allowed to improvise other derived questions if necessary. As for Group Storymaking, each participant conducted one Group Storymaking activity with 5-8 respondents, using an anonymous chat room of the online instant messenger Kakaotalk as shown in Figure 4. The participants followed the guidelines that we provided during this activity.

We also asked each participant to create 2 different personas: one from the result of 1:1 interviews and the other from Group Storymaking as shown in Figure 4. After 1:1 interviews, each participant transcribed the scripts to analyze them and create a persona. As for Group
Storymaking, each participant directly rephrased the responses from the Group Storymaking activity and put them in a persona template without extra analysis.

![Image](image_url)

Figure 4. An example of Group Storymaking activity (left) and the personas that a participant submitted (right), each based on the 1:1 interview (top-right) and Group Storymaking (bottom-right).

After all the participants finished user research and persona submission, they discussed the new method in debriefing focus group interviews. We conducted two focus group interviews (i.e. four participants in each group with an equal gender ratio) to evaluate and refine our method. We organized the two groups in a way that each participant was well aware of or even belonged to at least one target group of the other participants in the same focus group. In this way, the participants could evaluate each other’s personas from an actual target user’s point of view.

Each focus group consisted of three sessions. In the first session, we discussed pros and cons, memorable issues, and any general opinions on the Group Storymaking method. In the second session, we provided printed versions of all the eight personas that the participants in the same focus group had made. The participants were asked to evaluate and discuss those personas in order to validate whether Group Storymaking actually enabled in-depth understanding of an unfamiliar target user or not. The participants highlighted persona details that caught their eyes, either positively or negatively. In the last session, the participants shared opinions on the Group Storymaking guidelines to refine them together.

Transcripts of these discussions, Group Storymaking processes and persona descriptions were analyzed using affinity diagramming until recurring themes emerged.

**Findings**

A summary of the findings regarding the two methods is demonstrated in Table 2. In this section, we recapped these results as two primary findings: (1) quick and broad understanding of unfamiliar targets throughout Group Storymaking, and (2) trustworthy and insightful responses from Group Storymaking.

Quick and Broad Understanding of Unfamiliar Targets throughout Group Storymaking

The Group Storymaking method allowed for quick, broad understanding of an unfamiliar target group in an efficient manner. While deep-rooted needs and frustrations were revealed more during the individual face-to-face interviews, Group Storymaking method enabled designers to rapidly learn much about general features of a target group when designers have little or no knowledge of that target. The participants mentioned that they would conduct Group Storymaking first to gain basic knowledge about a target, and this knowledge would supplement follow-up 1:1 interviews to gain more in-depth information and find out tangible design opportunities:

P2: “When I was setting up interview questions, I didn’t know what to ask because I knew nothing about my targets, but Group Storymaking guided me what to ask, so it was easier to carry on.”

P5: “Group Storymaking helped me to understand the general, common features of the target, and interviews were used to find special particularities.”

For instance, there were notable differences in descriptions of the two ‘male university students who often play Futsal’ personas that P2 made. The persona’s frustrations found from 1:1
interviews (Figure 5) seemed were more intuitive and closer to design-related problems, but other biographic information was rather plain, superficial or too personal to be generalized as a concrete feature of the entire target group:

P2: “When you interview people and they have different opinions, I become confused because I don’t know how to decide which one is right. When details are different, I have to make an abstract persona. For example, when one says he makes a reservation in the morning and the other says in the evening, I write like ‘make a reservation THAT DAY.’ I make it vague.”

![Figure 5. ‘Male university students who often play Futsal’ persona based on 1:1 interview (translated, yellow=details that participants mentioned as representative and empathizing, blue=details that participants mentioned as unreliable or not empathizing)](image_url)

The other persona based on Group Storymaking (Figure 6) contained plenty of details about not only Futsal-related behaviors and habits but also his overall lifestyle which shapes it as a realistic persona, while his frustrations, although very empathizing, seemed to be complex, social problems from which designers need to extract practical value.
Besides, with little restriction of time and space, designers can implement Group Storymaking several times much more quickly than a 1:1 face-to-face interview. This enables designers to get used to an unfamiliar target group in a short time period:

P3: “Recruitment was really fast. [...] You can do this right in front of your desk, and so do respondents. So it was quick and easy. Also, after an interview I had to transcribe it, but there was no need for transcription in Group Storymaking, which made it more efficient.”

Trustworthy and Insightful Responses from Group Storymaking

Participants mentioned that the responses from Group Storymaking were vivid, honest and specific. During the Group Storymaking activities as in Figure 7, respondents who belonged to an actual target group collaborated to construct a hypothetical character in an anonymous third-person-manner based on not only their own previous experiences but also ‘expert’ knowledge that they had as they belonged to a certain target group. Since the respondents felt that they are not telling their own stories but a character A’s stories, they actively participated in the story-making process and generated more specific, frank responses than in the interviews:

P2: “People thought they were not telling their stories, but telling a character’s story during Group Storymaking, so they were more active. During the interview, the interviewees were not willing to honestly tell their secret stories.”

P6: “Because Group Storymaking is anonymous... During the interview, people see each other’s face and know who they are talking to, so they say things carefully, but when (they are) anonymous, they can say anything.”
Thus, responses generated from Group Storymaking were trustworthy and representative of the target groups. During 1:1 interviews, the designers interpreted each interviewee’s response as how s/he behaves, while during Group Storymaking the designers found the responses as how a random, ordinary person A in a target group generally behaves:

P1: “When I saw many people were agreeing with each other, I could be sure that their opinions were common and representative among most target users. When I was doing the interview, I could not be sure if my interviewees’ opinions were universal or just hers.”

P3: “People got inspired by each other and came up with more stories during Group Storymaking. [...] For me responses and personas made from Group Storymaking seemed more realistic and representative because they were what many people agreed on.”

What designers gained from Group Storymaking was not raw data that needed extra manual analysis but verified information that actual target users agreed on. As a result, designers’ subjective misinterpretation and assumptions that frequently happen during a raw-data analysis stage could be minimized. Throughout Group Storymaking a designer could extract numerous
commonalities which respondents have validated to be representative features of a certain target group, ensuring the reliability and representativeness of the responses gained.

**Discussion and Potential Benefits of Group Storymaking**

**Guide to Planning of User Research on Unfamiliar Target Users**

When designers have too little understanding in their target group to plan and carry out concrete user research, Group Storymaking can work as a universal, logical guideline to start with. Listing up interview questions or planning for observation can be a challenging task for designers who are unfamiliar with their target group, as they are not confident of what to ask and record. At this point, Group Storymaking guides them to obtain information that they need and to probe into their target step by step starting from ground zero. Especially, Group Storymaking helps designers to acquire even sensitive information from unfamiliar users. Since respondents anonymously tell a story as if it is not theirs, designers can gain what people are reluctant to tell specifically and/or honestly.

Because of this nature, Group Storymaking can be used as a rapid pre-user-research method for designers to quickly study and familiarize with a little-known theme or target group. A persona created by Group Storymaking consists of trustworthy, insightful details which are common features of the target group where that persona belongs to. Therefore, it helps designers to delineate in their mind a basic image of a representative user in a certain target group. Referring to personas and design scenarios created from Group Storymaking, designers can screen and recruit relevant participants and set up a sound research plan.

**Potential as a New User Study Tool with a Bigger Number of Participants**

Group Storymaking minimizes the role of designers in the process of user data collection by involving a group of actual target users in that process. A possible future scenario can be increasing the number of respondents who participate in one Group Storymaking activity. We suggest applying crowdsourcing to Group Storymaking so that a statistically meaningful number of people can participate in real time to construct design scenarios and personas composed of abundant firsthand user data even without a designer’s control. Also in this way, a digital archive is expected to be developed to work as a computationally supported user study platform, where various types of scenarios and personas are created, saved, shared among designers, and employed for diverse design projects.

**Limitations of the Study**

This research is based on a sample of Korean design student participants aged between 23 to 26. It is necessary to validate the new method with other design researchers and practitioners that belong to a more general global population before generalizing the findings. Beyond this, despite our efforts to deal with a variety of design cases and target users, not all the situations where unfamiliarity is often an issue were not covered in this study, such as designing for children, the elderly or the disabled. We leave these investigations to future work.
Conclusion

We developed Group Storymaking as a new method for enabling designers to gain broad understanding of unfamiliar design project themes and target user groups as well as to elicit trustworthy, specific and representative information about that target by directly engaging even remote target users in the design process. Based on a fiction writer’s ideation technique, Group Storymaking utilized the method for making fictional stories to create factual stories of real users.

We found that a storyline with a character in a fiction writing and a design scenario with a persona have common features, and therefore the ideation technique that fictions writers use could be applied in a design process. Most responses from Group Storymaking based on our guidelines were perceived as insightful, representative and believable by actual designers. The new method is quickly and easily implementable, and it can involve target users in a design process with less time and cost commitment. Designers can also use Group Storymaking as a rapid pre-user-research method to quickly get familiarized with unknown theme and target group.

Furthermore, we suggest combining our method with crowdsourcing. By doing so, a persona archive as a new user research tool can be developed. A statistically meaningful number of actual target users are expected to offer valuable stories throughout the group interaction and communication without designers’ great efforts in planning and carrying out qualitative field research.

Acknowledgement

We would like to thank all the participants and colleagues who we engaged in this work. This work was supported and funded by 2016 Winter-Spring KAIST URP Program and partially by the ICT R&D program of MSIP/IITP [R7124-16-0004, Development of Intelligent Interaction Technology Based on Context Awareness and Human Intention Understanding].

Hankyung Kim

Hankyung Kim is a MS candidate in the Department of Industrial Design at KAIST. Her research interest is creative user experience design for intelligent agent and IoTs. Kim received
Soonju Lee
Soonju Lee is now working in mobile game industry. Her research interest is mobile game user experience including exer-game. Lee received her BS and MS in industrial design from KAIST.

Youn-kyung Kim
Youn-kyung Lim is an associate professor in the Department of Industrial Design at KAIST, where she leads the Creative Interaction Design (CIxD) lab. Her research interests have been in the areas of experience-centered design and prototyping in HCI, with a design-oriented perspective, especially focusing on enabling creative interaction design. Lim received her PhD in design from the Institute of Design at the Illinois Institute of Technology in Chicago.
Developing a Matrix for ‘Designerly Way of Creating Shared Value’ (DCSV): Four examples of CSV via perspectives of design

Kyulee Kim, PhD Candidate of The Hong Kong Polytechnic University, Hong Kong, kyulee.kim@connect.polyu.hk

Abstract

Today, while profit maximization is still the bedrock of the capitalist model, people have embraced the idea of social contribution as a useful strategy in businesses. In this recent movement, Creating Shared Value (CSV) strives for a win-win solution that creates both social and business value. While in its early stage, CSV is showing promise and potential; society is witnessing a paradigm shift from practices of corporate social responsibilities (CSR) to CSV which is more sustainable and effective approach. Since Porter and Kramer originally introduced the concept in 2011, CSV’s application has expanded to many areas of business management, but it has not been discussed comprehensively in design research as of yet.

The title of this paper, “Designerly Way of Creating Shared Value” (DCSV) is inspired by Nigel Cross’s famous book, *Designerly Way of Knowing* (2006). ‘Designerly’ is an adjective describing ‘how’ designers think and behave that is different from professionals in scientific disciplines. The aim of this paper is to propose a new matrix illustrating the link between creating shared value and design, and to systemically describe the existing examples of DCSV (Cross, 2016). The paper will begin with an introduction to the concept of CSV followed by a brief literature review on CSV in design research. The second part will focus on demonstrating the new DCSV matrix by illustrating the four examples that exemplify it.

*Keywords*: Creating Shared Value (CSV), Business & Social Innovation.

Introduction

Although the practice of CSV may have been around for a longer time, the theory of itself was first published and termed in 2011 by two business professors, Michael Porter and Mark Kramer, in an effort to increase the awareness of CSV’s capabilities as a competitive business strategy (Porter & Kramer, 2011). CSR activities were conventionally organized to demonstrate a company’s social contribution with its non-profit activities. CSV is a concept that evolved from CSR with an aim to create a single solution for both the society’s and company’s gain. In essence, CSV aligns the interest of the business and the needs of the ecosystem, society, in which it operators in.

Meanwhile, design as an “interdisciplinary discipline” (Cross, 2007, p. 46), has a long history of satisfying multiple stakeholders in one project by collaborating with other fields. Scholars have illustrated numerous cases where design played an imperative role.
in developing a successful strategy in business (Liedtka & Ogilvie, 2011; Martin, 2009; Pink, 2006; Verganti, 2009). In addition, philanthropic values have been a common theme in design activities; there has been many design researchers discussing socially and ethically responsible designs (D'Anjou, 2009; Tromp et al., 2011; Wang, 2015). These examples highlight design’s contribution in competitive strategy in businesses as well as philanthropic practices. This research is to build upon the tacit optimism in discovering ways of design’s contribution to create shared value. This research was initiated by the curiosity of finding various situations where socially responsible design can also accomplishes economic success or where design finds profit-making businesses opportunities by doing socially good. If a business seeks for such an efficient solution and finds new business opportunities in a creative way, design not only can enhance the process of creating shared value, but also find new areas for innovation.

CSV is a term invented from the field of business rather than field of design. Moreover, there has been very little research done defining the coded knowledge to support designers who seek to create shared value. Therefore, while there is potential for further progress in this new field, currently a gap exists between CSV and design due to the lack of familiarity among designers; additional knowledge needs to be discovered in order to effectively incorporate the concept of CSV in design. The aim of this paper is to demonstrate a general framework of CSV that designers can refer to when researching or practicing design for creating shared value.

Literature Review: Existing design research on CSV

A vast amount of studies exists on social design, socially responsible innovation, design management, and design as marketing or business strategy. It is either society-centric value creation of design or business-centric value creation of design, but fails to satisfy both the needs of society and business. Since idea of CSV is still young and developing, direct connection of CSV in design research have yet to be made. This section explores few existing design studies that touch directly or indirectly upon the ideas of CSV.

In Design Issues, a design researcher, Thorpe raised a meaningful question around “Design’s Role in Sustainable Consumption” (2010). The author’s argument stems from design’s long history of creating consumer products that cause many social problems. The paper ponders upon issues on consumerism and ways that design can participate to cure the problems while simultaneously remaining as a marketing strategy.

In the Design Management Review (DMJ), Cooper and Koo, published case studies of product designs as a means of corporates’ social responsibility. In the article, they also briefly point out Porter and Kramer’s CSV as a further option of socially responsible product design (Cooper & Koo, 2011). Followed by the article in DMJ, in 2016, Koo published an article, “The Role of Designers in Integrating Societal Value in the Product and Service Development Processes” at International Journal of Design. Koo again focused on discovering the main motivations and roles of designers’ creating socially responsible product and service design (SRD) as source of corporates’ social responsibility (Koo, 2016). Koo briefly identified the possible shared value result, as a notion of Porter and Kramer’s CSV, by indicating creating SRD may accomplish economic profit.
On the other hand, Brand and Rocchi in “Rethinking Value in a Changing Landscape,” that was published by Philips, underlines that design solutions that cure social problems are worth to look at for sustainable economic growth as opposed to conventional monetary-centered industrial developments (2011). In the paper, the two authors claim that social designs can widen the audience of design and business; thus social problems can actually become opportunities for both design and businesses.

Den Ouden in Innovation Design (2011) and Advanced Design Methods (2013) enlightened readers that there are four levels of perspectives and stakeholders to consider during the design process. She introduced idea of shared value in the language of design researcher. This is also one of the first direct indications to the terminology CSV in design research. Den Ouden not only explored challenges of satisfying more than two stakeholders in one design solution, but also elucidated benefits of shared values.

**Limitation of Existing Research on CSV and Research Difficulties**

Reviewing Porter and Kramer’s CSV and existing design research on CSV in previous section, there are some limitations and research difficulties. First of all, there are very limited resources of design research on CSV. The common contribution of the six academic literatures was to enhance the awareness of shared value in the design community and introduce new design opportunities in shared value. However, most literatures neither show an actual design project organized to simultaneously create social and business value, nor discuss roles of design in CSV. The absence of design research in CSV may prove the need for additional study, but potential obstacles stand around the development of the topic.

Secondly, one difficulty may rise because the concept of CSV is rather at a developing stage compared to socially responsible design and business. CSV has evolved from CSR with an aim to fulfill both societal and business needs through a mutually beneficial solution. CSV is an important concept to bear in mind when an individual has to solve a social problem in an organization or to create a CSR activity. For example, most successful CSV solutions are created from re-organizing companies’ existing systems or utilizing its most accessible resources. However, CSV cannot cover all social activities. Thus, CSV may not be the best derivative of CSR because of its constraints of having to create both social and business value (Crane et al., 2014).

Another obstacle comes from the challenge of incorporating CSV with design because it was originally made as business theory, not design. Therefore, in order to successfully merge the original objectives of CSV, beyond its application in design, the study also needs to prove it can deliver sustainable growth to business for it to be adopted.

**Developing a Matrix for ‘Designerly Way of Creating Shared Value’ (DCSV Matrix)**

In order to select relevant DCSV examples and interpret each case under perspectives of design, building a structured system is necessary. A matrix for ‘designerly way of CSV (DCSV
Matrix) Figure 2 provides twelve subgroups within the topic. There are four different types of CSVs, including CSR on the y-axis, and there are three categories of design on the x-axis. It total, the matrix produces twelve different types of DCSVs.

According to the background research on CSV, there are three levels of CSV with CSR activities categorized as level zero (Lee et al., 2014). While CSR fulfills social responsibilities, at CSV level 1 new business strategy enhances a product and market by reconceiving the existing one, at level 2, CSV improves productivity in company’s existing value chain, and at final level, CSV enables development of the “entire cluster” (Porter & Kramer, 2011; Lee et al., 2014, p. 469).

In the matrix, design is segmented into three different levels. First established by Danish Design Centre in 2003, The Design Ladder has been adapted by various design scholars including Brigitte Borja de Mozota and Cara Wrigley. Having set non-design value as level zero, the first level of design is focused on style and aesthetic value. At level two, design is described as process; at this level, design is seen as a method to develop rather an early stage for the end result, which will need multidisciplinary efforts to achieve. Finally, step four is where design blossoms into a strategy and functions significantly towards innovation. At this level, design is intrinsically embedded into a company’s core vision and development process by taking a role in creating tangible value (Kretzschmar, 2003, Mozota, 2006, Wrigley & Straker, 2015).

The categorization of CSV is very relevant to understand careful development of CSV according to its level of sophistication. Also, The Design Ladder fits well to describe contribution of design in each of cases of designerly way of CSVs, because this classification was built originally to illustrate various roles of design with an economic and business perspective.
Four DCSV Examples

Four examples of DCSVs are found from various sources mostly from desk research. The following narrative data was acquired from reviewing and analyzing the companies’ website and other linked articles for their marketing purposes.

Example 1: A Furniture Company - Type C1 and D1

A globally successful furniture company developed a temporary online platform to form a sharing economy for the second-hand furniture market. The furniture company uses its website as online store of their own products to advertise the lists of second hand furniture items. The company launched a new space on its online platform to link the buyer and seller of the second-hand furniture. Moreover, it utilized internal design resources to restore the old furniture and advertise them for free through their own online sales channel. The company articulates and promotes products according to the advertising standards the company use for selling own products. The company not only facilitated the sales of second-hand furniture, but also contributed to waste reduction. This serves as a case where a free creative service translated into additional sales for its own furniture (https://vimeo.com/77769027).

Example 2: A Toy Company - Type C2

An globally renowned toy company designed a new packaging that is more durable, lighter in weight, and efficient in size. The package is developed not only to reduce production cost, but also lower the carbon emission during the distribution process, and save larger amounts of cardboards to “guarantee that trees will not be used at a greater rate than the forest can reproduce, that animal and planet life will be protected, and that forestry workers have fair working conditions” (https://www.lego.com/en-us/aboutus/responsibility/ourstories/smaller-boxes). It is a win-win strategy; the new solution enhances the company’s profits by reducing manufacturing cost. Moreover, the new package design also serves an ethical purpose of benefiting the environment and forestry workers.

Example 3: A Jewelry Brand - Type b1

There is a start-up Jewellery brand, whose products are made from recycled bombshell brass in Cambodia. The brand creates elegant jewellery targeting for luxurious fashion industry, but aims to send an important message of the serious social problems caused from abandoned minefields in Cambodia. The Jewellery brand tries to imply subtly the importance of peace by referring to countless injuries and deaths of innocent local residents from uncontrolled landmines in the region. Moreover, the company contributes to society by manufacturing its products locally and hiring the local craftsmen. The purpose of its socially responsible campaign, main source of inspiration of the jewellery design, main product material, major source of company’s profit, and the core story for the marketing are all intrinsically interrelated (https://emiandeve.com/category/materials/).

Example 4: A Smartphone Manufacturer - Type d2 and d3

The motto of a start-up smartphone manufacturer is to create a more transparent business. It
designs smartphones that are long lasting, convenient to repair, and easy to reuse and recycle. Also, their business aims for social impact by increasing the awareness that illegal and dangerous smuggling occurs behind the scenes of making fancy mobile phones. A smartphone in general constitutes of 38 materials such as gold, iron, copper. These materials are often dug and processed from developing counties in Africa, and there are various social problems caused from the illegal trading between the local material producers and global distribution agencies. The founder started his innovative journey in hopes to alleviate this social issue. First, the company aims to create a good working environment for the company’s employers and mine workers by acquiring necessary minerals for its product only from ‘fair’ trading. With the socially responsible purpose, it also designs phone that is aesthetically and functionally attractive for the users to persuade choosing the ethical and socially responsible products over other more popular smartphones in the market (https://www.fairphone.com/en/).

Discussion 1: DCSV examples from large enterprise vs. SMEs

First, it is necessary to clearly differentiate the characteristics of DCSVs from large enterprise and small and medium size enterprises (SME). Please note SME, according to European Union, a company with annual revenue less than 50 million Euros or fewer than 250 staff members (http://ec.europa.eu/growth/smes/business-friendly-environment/sme-definition_en).

The first two examples belong to global companies, IKEA and Lego. The last two examples are stories of two start-up companies, Emi & Eve and Fairphone, both of which were established in 2013. All four examples demonstrate clearly how DCSV works and how design is integrated into the process of creating shared values. However, there are few distinctive features that are unique from one group (DCSVs in large enterprise spectrum) from the other group (DCSVs in SME spectrum).

![Figure 5 (left): DCSV in Large enterprise spectrum](image1)

![Figure 6 (right): DCSV in SME spectrum](image2)

DCSVs in the large enterprise spectrum often launched as temporary CSV activities as a
means of a marketing strategy or corporate’s social duty. Furthermore, CSV solutions in large companies only partially influence the core value of the entire company because there are many other active programs in parallel, because of other obligations or interests to fulfill. On the other hand, for smaller companies like Emi & Eve and Fairphone, CSV solutions are rather permanent, and the interest of business and the society are completely aligned from the beginning; smaller organizations’ core social mission and source of profit are more intrinsically related. For example, because Emi & Eve and Fairphone are start-ups that were planned and activated by philanthropic stimuli from the initial stage, the social and business value entirely overlap (figure 6). Meanwhile, the metaphor depicted in Vann Diagram (figure 5) shows how the interests of the company and the society meet only in the intersection. Although there are some different organizational traits, in both groups, whether the size of company is big or small, tackling social problems became a good motivation for creating innovative products, services and systems.

Discussion 2: Using DCSV matrix to understand the four examples (Figure 7)

The first example describes IKEA’s free eight-week-long eventful service. The story fits into C1 in the DCSV matrix. IKEA’s sharing economy platform for second-hand furniture improves productivity from existing business operations. Conventionally, as a furniture manufacturer, selling non-profit making products through their online platform is counterintuitive it competes with its new products. However, IKEA found peoples’ recurrent needs, selling and dealing with old furniture when prospective customers buying their new furniture. Therefore, such services increased the firm’s revenue by adding extra
reason to visit the website and offering a convenient service for prospective buyers of IKEA furniture. Moreover, IKEA utilized their product design resource to polish the old furniture to increase their commercial value and professionally photographed and published on the website to properly advertise. To sum-up, design has stylistic and decorative role for creating shared value in the example one. Moving forward, IKEA’s free platform lightly touches the CSV 3. If the service expands globally, it can initiate a cluster development because repairing and recycling old furniture can help not only cutting unnecessary waste, but also benefit the seller and the next owner of the old furniture.

The second example, Lego’s “Big Planet Saving in Smaller Boxes” project satisfies two criteria for TYPE C2. In the section of the matrix, design appears as process, and level of CSV is to achieve improve efficiency in company’s existing value chain. The new package design redefined the productivity in both economical and societal value system. Furthermore, the design took in a role during the process of developing new outcome to facilitate the company’s ethical goal while the final end product, which is efficient packaging design, aesthetically and ergonomically considered. The role of design is clear and package design plays a pivotal role during the process of making the plan realized.

Applying the various criteria from the DCSV matrix, the heroine of the third example, Emi and Eve is a case of CSV 1, “reconceiving product and marketing” (Lee et al., 2014, p. 469) by raising a critical social issue in Cambodia and by increasing awareness of important human value. Moreover, the brand is starting to expand the CSV1 into CSV3. The company is at the early stage of planning for collective development for both the company and local community by employing local craftsman and by re-investing some of the profits for vocational training. Also, Emi and Eve is a good example of design as style where business is facilitated by stylistic and aesthetic power of design. Design plays a pivotal role during the process of launching the socially responsible business. All in all, a case of Emi & Eve situates b1 that starts to expand towards d1.

The final example is a story of type d2 and d3 in the DCSV matrix. Fairphone built new smartphone design and manufacturing system to solve the social problems caused during the procedure of illegal material trading. First, design plays a significant role of this example. Design is essentially embedded to the business during the process of innovating a new socially responsible business solution from the early stage; hence, the example satisfies the criteria for ‘design as process.’ Later, design becomes a pivotal business strategy that makes the business competitive in the extremely competitive smartphone market. Looking at the ‘y-axis’ of the matrix, Fairphone is based on CSV 3 model because the business aims for cluster development; it creates a business that cures the social problem and adopts the same problem as the competitive business strategy.

Conclusion

This paper introduced creating shared value (CSV) under the scope of design research. The research offers a new system that enhances the understanding of any other examples of CSV by categorizing CSV into four sub-levels and design into three sub-groups. Moreover, the four DCSV examples demonstrate various roles of design in the facilitation of creating shared value.
Moreover, this study is only in its initial stage and requires further research area development. Various cases can be examined and interpreted through the DCSV matrix. Ideally understanding the components of the DCSV can help designers to plan systemically creating shared value. Accumulative data from more examples in the future with detail descriptions may extrude various facts such as common key success factors and additional design value creating levers.

Nature-inspired organizational design framework for open collaboration platform development

Sojung Kim, Ulsan National Institute of Science and Technology, Ulsan, South Korea, sojung@unist.ac.kr
Joon Sang Baek, Ulsan National Institute of Science and Technology, Ulsan, South Korea, joonsbaek@unist.ac.kr

Abstract

Over the last two decades, for-profit and non-for-profit organizations have increasingly adopted open collaboration, such as open innovation and crowdsourcing, as a strategy for innovation. Information and communication technology (ICT) has played a major role in forming open collaboration communities, but organizational design also needs to be considered to encourage the active participation and collaboration of actors. Nonetheless, organizational design aspect has seldom been addressed in developing open collaboration platforms. In this research, an organizational design framework for open collaboration was developed through a nature-inspired design approach. This framework suggests that the self-organization mechanism of social insects provides inspirations for the design of the platform, especially in terms of setting simple rules to induce behaviors of the actors and facilitating interactions among them. Since the open collaboration strategy depends on external actors who are not in employment relationship, an organization cannot force their contribution. Accordingly, the organization’s capability to induce the spontaneous participation of actors is essential, and it implies the potential role of designers in platform design based on a thorough understanding of actors. We thus claim that designers can bring a new perspective to organizational design. Open collaboration platforms serve as an exemplar in which designers contribute to the design of an organizational environment that fosters collaboration.

Keywords: Bio-inspired design, biomimetics, Crowdsourcing, Open Innovation, Platform strategies

As social and environmental problems become increasingly complicated, social innovators are adopting open innovation strategies (Murray, Caulier-Grice, & Mulgan, 2010). This collaborative approach to innovative problem-solving, such as open innovation and crowdsourcing, is referred to as open collaboration (Levine & Prietula, 2013). In open collaboration, the involvement of stakeholders including citizens in social innovation process is critical to understanding problems and generating ideas in daily life (Aitamurto, Holland, & Hussain, 2015; Bjögvinnson, Ehn, & Hillgren, 2012). Thanks to the development of information and communication technology (ICT), now more stakeholders can participate in the design process in a more convenient way through social media and social network services.
(Hagen & Robertson, 2012). Considering expanded design scopes into systems and environments (Bjögvinnsson et al., 2012) and open collaboration cases based on ICT (Forte & Lampe, 2013; Seltzer & Mahmoudi, 2012), collaboration platforms could be a proper design object. By designing platforms which are attractive and convenient for the crowd, designers would be able to support the open collaboration of diverse stakeholders and contribute to social innovation.

Although advanced ICT has taken a critical role in facilitating crowd collaboration in diverse fields, it is not a sufficient condition to take advantage of collective intelligence. Organizational design that is suitable for increased amount of information and new relationships between stakeholders should be taken into account (Snow, 2015). How, then, should the organizational design approach be modified for and reflected in the collaboration platform design? In this research, self-organization, which is introduced as one of the principles of open innovation (Murray et al., 2010), was given prominence. In particular, self-organization mechanism of social insects was investigated since bees and ants have been appreciated in the management field for their excellent self-organized performance based on simple rules (Bonabeau & Meyer, 2001; Mead, 2014). The potential of the natural ecosystem as a source of inspiration for innovative solution for organizational problems has been suggested by several studies (Fewell, 2015; Holbrook et al., 2010; Mead, 2014) and empirical cases (Bonabeau & Meyer, 2001). Since both a social insect colony and a community for open collaboration pursue collaboration based on reciprocal relationships among a crowd of members (Gulati, Puranam, & Tushman, 2012), self-organization mechanism of social insects could be a good source of inspiration for designing an open collaboration system. Accordingly, this research aims at suggesting an organizational design framework for open collaboration based on self-organization phenomena in nature. Along with this aim, the following research questions will be addressed:

1. **How do we apply the mechanism of self-organization to organizational design for an open collaboration platform?**

2. **How can designers contribute to applying the self-organization mechanism to organizational design for an open collaboration platform?**

**Open Collaboration**

Diverse studies have shown different views on open innovation, crowdsourcing, and open collaboration as delineated in Table 1.

Previous studies on open innovation, crowdsourcing and open collaboration imply that making a clear definition of and distinction among them is not a simple work. Nonetheless, in this study, open collaboration was selected as a representative term to emphasize the significance of collaboration in social innovation. To integrate the findings from the literature reviews, open collaboration needs to (a) involve a crowd, (b) encourage voluntary participation of a crowd, (c) provide a mutual benefit, (d) facilitate interaction and synergy among crowd members, and (e) allow transparent and participatory decision-making.

The requirements of open collaboration can be implemented in online platforms thanks to advanced ICT (Cabiddu, Castriotta, Di Guardo, & Floredu, 2013; De Vreede et al., 2013; Forte & Lampe, 2013). However, this does not mean that technologies promise the active collaboration of a crowd. An open collaboration community engages autonomous participants of equal status through an open system, so a conventional organizational structure and management method are unfavorable for attracting these participants (Gulati et al., 2012). Therefore, the organizational design for open collaboration aims at integrating different actors into a networked community and allocating resources, tasks and decision-making power for mutual benefit of all stakeholders (Baldwin, 2012). The significance of organizational design is emphasized especially when technologies are utilized to induce the participation and collaboration of the crowd (Kornberger, 2016).
Organizational design for open collaboration

In accordance with the importance of organizational structures in strategy change (Fjeldstad, Snow, Miles, & Lettl, 2012; Snow, 2015), several suggestions on organizational forms for open collaboration have been made recently. The previous studies introducing the elements of organizational design for open collaboration are summarized in Table 2.

Table 2 The summary of organizational design elements for open collaboration

<table>
<thead>
<tr>
<th>Source</th>
<th>Elements of Organizational Design for Open Collaboration</th>
</tr>
</thead>
</table>
| Meta-organizational design (Gulati, 2012) | **Permeability of boundaries**  
- the strictness of the procedure to become a member of a community  
- a closed boundary is easier to manage  
an open boundary is better for inviting more participation  
**Degree of stratification**  
- the differentiation of roles and the status of members  
- A hierarchical structure: simple management and higher motivation to take higher status  
- A heterarchical (equal) structure: higher ownership and attachment to the organization but difficulties of reaching an agreement |
| Actor-oriented organizational scheme (Fjeldstad et al., 2012) | **Actors** who have the capabilities and values to self-organize  
**Commons** where the actors accumulate and share resources  
**Protocol/processes/infrastructures** that enable multi-actor collaboration |
| The principles or organizational design for business ecosystems (Baldwin, 2012) | **Proprietorship of core components**  
the owners of a platform, which is an irreplaceable core component in the business ecosystem, have discretion in the business  
**The number of for-profit owners of the core components**  
Participants of the platform, who produce optional components, prefer platforms with small numbers of owners so that they can claim a larger portion of the profit |
| Task and knowledge contingencies (Lakhani et al., 2013) | **Task decomposition**  
Open innovation strategy is advantageous when the tasks are modularizable  
**Problem-solving knowledge distribution**  
Open innovation strategy is advantageous when the knowledge required for problem-solving is broadly distributed |
| Design principles for organizing distributed innovation (Kornberger, 2016) | **Interface design**  
- manage the interactions and information exchanges among the actors  
- ’meeting points’ mediating inside and outside the organization and the interface for smooth communication between subsystems  
**Architectures of participation**  
- Modularity: the tasks should be modularized so that scattered actors can handle the tasks independently  
- Granularity: the size of the task modules must be small enough to be completed by the members |
- Integration efficiency: the completed modules of the tasks should be easily and efficiently integrated

**Evaluative infrastructure**
- visualize implicit values of the work process and results
- underpin the decision-making process
- be perceived as a new value in the community

Although the aforementioned five studies have different frameworks to articulate the organizational scheme for open collaboration, they embrace a common point: a desirable organizational design for open collaboration necessitates certain environmental conditions for collaborative and communication activities. These activities facilitate the actors’ voluntary participation.

To maximize the performance of the autonomous independent units, they need to be supported by the platform (Gray & Vander Wal, 2014). On a platform, technology facilitates the interaction between the actors and resources so that they can generate and exchange value (Parker, Van Alstyne, & Choudary, 2016). The problem is that developers and designers are not used to designing a platform that can support the diverse interactions in a large user community (Gray & Vander Wal, 2014).

Designing the local level rules to induce global-level behavior is extremely tricky because of the difficulties in anticipating the global pattern from the local conditions (Elmenreich & Friedrich, 2009). Self-organization in nature has the characteristics that are in many ways common with the organizational forms for open collaboration (Gulati et al., 2012). We may then be able to learn from it to design protocols and platforms for open collaboration.

**Mechanism of self-organization**

Self-organization refers to “a process in which pattern at the global level of a system emerges solely from numerous interactions among the lower-level components of the system (Camazine, 2003:8).” Self-organization can be observed from diverse types of living and non-living entities, such as a school of fish or a pattern in tidal sand. Nonetheless, the collaboration of social insects such as nest construction by bees and foraging by ants (Detrain, Deneubourg, & Pasteels, 1999) are the most representative examples that show the power of self-organization.

The self-organization of social insects emerges from feedback loops based on iterative local interactions (Fewell, 2015). An entity acquires information through direct communication with other individuals or through so-called stigmergy, indirect communication using a shared environment as the media. This information is transmitted in the form of either signals or cues: signals are the conspicuous stimuli that have developed in the evolution process, the cues are incidental and subtle (Camazine, 2003). Based on the signals and cues, individuals make decisions how to behave. In the process, their decision-making is affected by biological and
physical parameters: biological parameters are innate characteristics of the organisms, and physical parameters are related to environmental or physical conditions.

Finally, the accumulation of individual interactions leads to positive and negative feedbacks for the colony. Specifically, when the colony members find an attracting signal made by co-workers, more of them participate in the activity, and the signal becomes even stronger. After the task is done, they stop generating the signal, and the collaborative group dissolves naturally (Allen, 2010). In this decentralized manner, the community resolves intricate problems at a systematic level.

To conclude, self-organization enables a community to achieve complex and large-scale outcomes through the collaboration of a large group of members. The individual members communicate locally, make decisions, and enact them according to a set of simple rules programmed in them and the environmental changes. Figure 1 summarizes the mechanism of self-organization. In this mechanism, a single actor does not need to understand the global conditions nor need direct control; it is similar to the organizational design approach for open collaboration. Self-organization strategy reduces the burden of information acquisition, information processing, and decision-making on individuals (Camazine, 2003). Furthermore, the failure of one or several individuals is not critical for the success of the community, and communities can easily adapt to environmental changes (Bonabeau & Meyer, 2001). For these advantages in terms of robustness and flexibility, the self-organization strategy is effective in handling dynamic problems (Holbrook et al., 2010). Considering the strengths of self-organization and the analogy between self-organization and the organizational design approach for open collaboration, self-organization can be an inspiration for the design of open collaboration platforms.

Figure 1 Summary of the self-organization mechanism
An organizational design framework for open collaboration

Based on the literature studies on organizational design for open collaboration and the self-organization mechanism, an organizational design frame was established. This framework consists of 5 elements: (a) organizational goals / required tasks & resources, (b) actors, (c) commons, (d) task design, and (e) information communication. The issues addressed in the previous studies are associated with these elements of the framework (Table 3). This framework was then applied to designing the structure of an open collaboration platform (Figure 2).

(a) Organizational goal / required tasks & resources

An organization is composed to achieve the organizational goals, and it is equivalent to the global-level pattern that emerges from the self-organization approach. According to the goal, the tasks to be executed are clarified. Each task entails requirements to be completed, such as capabilities or resources, and these resources include information and human resources as well as material resources and facilities. After clarifying the organizational goal, tasks and requirements, the suitability of open collaboration strategy is evaluated depending on the decomposability of tasks and the degree of knowledge distribution. Open collaboration is effective when the tasks can be divided and assigned to multiple workers and the necessary knowledge can be acquired only through the collaboration of several actors.

(b) Actors

Basically, actors are invited through an open call (Estellés-Arolas & González-Ladrón-De-Guevara, 2012). However, the high permeability of a community boundary includes the risk of involving disqualified members and contributions. To avoid such a risk, an organization can provide attractive elements for target users and execute prescreening or post management on members’ contributions.
Analogous to the biological parameters of social insects, the intrinsic characteristics — mental model, needs and capabilities — of actors are also the important factors in organizational design. Even though the community members are provided with same stimuli, the behaviors of individuals may vary depending on their intrinsic parameters. Thus, the types of actors and their intrinsic parameters are taken into consideration when designing the protocols that influence the active participation and collaboration of actors. In the same context, stratification of an organization is determined depending on whether the desire for a higher position or ownership is influential in motivating a community.

(c) Commons

Commons indicate resources shared by the platform users, including the platform itself (Fjeldstad et al., 2012). Sharing common resources and the environment freely is more effective in encouraging the participation of actors than having exclusive ownership. Regarding self-organization phenomena, commons also include the influential factors on decision-making and the behavior of actors. Through the commons — namely, stigmergy — actors can engage in indirect communication. Thus, the environmental parameters of commons are highly relevant to the information communication aspect of platform design.

(d) Task design

The tasks identified along with the organizational goals are modularized with consideration of the motivations and capabilities of actors so that they can take charge of each module independently. The modules are designed to be integrated easily after all the modular tasks are finished. In particular, positive and negative feedback systems control the collaboration of actors and integrate their work as a collective outcome. In this context, considering how to utilize the information on progress or outcomes of each task as cues or stigmergy can improve the efficiency of the information system for open collaboration.

(e) Information communication

In a self-organized community, entities produce information intentionally (signals) or incidentally (cues), and this information is exchanged through direct (peer-to-peer) or indirect (stigmergy) communication. Especially cues and stigmergies are useful for facilitating expeditious communication. A reservation system is a good example: when a customer chooses a seat, the information on seat occupancy is automatically updated and shared with other customers through the seat map, without intentional or direct communication. Thus, the suitable methods of information generation and transmission need to be adopted depending on the context and availability of the information sources.

With respect to evaluation, the scoring of collaborativeness and the quality of outcomes can enhance the motivation and collaboration of actors. Furthermore, collective decision-making
based on the evaluation of individuals is an effective strategy to derive optimized solutions. Since the new values formed in the evaluation process are strongly related to the motivation of actors, the evaluation system designed in line with the intrinsic parameters of actors can encourage participation and collaboration without monetary rewards.

**Analysis of an existing platform using the framework**

For a better understanding of the applicability of this framework to the platform design, Adopt-A-Hydrant, a platform to support the crowdsourcing of hydrant maintenance in Boston, was analysed using the framework.

(a) Organizational goal / required tasks & resources

The purpose of this platform is keeping the hydrants available and accessible for emergencies. After snow falls, more than 13,000 hydrants in Boston need to be shovelled and cleared of snow. This task can be executed in a more efficient way when it is shared by citizens. The residents who live near a hydrant and possess the equipment and labour capabilities to remove the snow would be suitable for this task. In addition, the information on the location and the condition of the hydrant to be managed is required.

(b) Actors

This service is provided by the city of Boston, but participation on this platform is entirely dependent on the individual citizen. Besides, Adopt-A-Hydrant does not entail a hierarchal structure in its user community.

(c) Commons

In this case, the hydrants in Boston are the objects to be managed and are the media through which citizens can interact indirectly with each other. While the hydrants are physical resources, the Adopt-A-Hydrant online platform and the map with the marking of the hydrants are the digital environment to obtain the required information to adopt a hydrant.

(d) Task design

The task of maintaining the hydrants in Boston was modularized by cleaning one hydrant around the home or the workplace. This modularized task is simple and manageable enough to be handled by individual citizens. Since a modular task includes the entire process of hydrant maintenance, the performance of the tasks hardly affects each other. Thus, the integration of tasks leads to more hydrants being cared for rather than the higher degree of completion of tasks.
(e) Information communication

The most significant information for carrying out the task is the location and adoption status of the hydrants. The platform provides this information on the map: the hydrants already adopted and those that have not yet been adopted are marked with green and red location symbols, respectively. The participants can look through the map or input the address to look for an adoptable hydrant. When an actor finds an appropriate one, he or she can give the hydrant a nickname and register it for adoption by clicking on a red location symbol, whereas clicking the green location marks shows the name of hydrant and the adopter. If a citizen finds a hydrant covered with snow, he or she can send a reminder to the adopter through this hydrant information page. The registration of adopting hydrants is a signal issued by the citizens, but the current state of hydrant adoption in Boston is visualized on the map as the cue.

Discussion

Application of the self-organization mechanism to organizational design

Considering the complexity and broad scope of problems handled in open collaboration platforms, self-organization, which has advantages in distributing the burden of information processing and decision-making, could be a useful strategy. This research reveals the similarities between the self-organization mechanism and the functioning of platforms for open collaboration: achieving organizational goals through indirect control based on autonomous decision-making and activities. Moreover, self-organization mechanism provides some useful concepts which have not been addressed in the previous studies on organizational design for open collaboration. For instance, we can enhance collaboration through applying actors’ intrinsic attributes to setting the platform policies, adopting the suitable communication mode between direct interactions and stigmergies or between signals and cues, and facilitating positive or negative feedbacks. Accordingly, we suggested an organizational design framework for open collaboration based on self-organization phenomena.

In addition, the analysis of Adopt-A-Hydrant platform using this framework implies how it could contribute to open collaboration platform design practice. To be specific, the names of a hydrant and its adopter displayed by clicking the green location marks are the elements that make the adopters feel responsibility and attachment to their hydrants. However, this platform lacks the functions for positive feedback. To maximize the effect of stigmergy, the platform could provide processed data such as total number of adopted and unadopted hydrants or local adoption rate, and set communal goals to stimulate the community members. Moreover, functions for inviting neighbors through inter-actor communication could encourage the participation of new adopters. As this analysis shows, elements of this self-organization framework could be utilized as a standard for diagnosing the existing platforms, and further, a guideline to design a new platform. Although the potential of this framework need to be validated through empirical studies, self-organization would be worth considering as a strategy to raise the social impact of an open collaboration platform.
Role of designers in organizational design

While the power of design thinking and design methods has been valued in the management field, the contribution of designers in organizational design has been scarce. In the organizations in industrial economies, the decision-making authority over the organizational form and management strategy has been monopolized by the management, and employees were directly controlled by their supervisors. Thus, designers could rarely intervene in organizational management issues. However, in the organizations using the open collaboration strategy, tasks are performed by external actors who do not work exclusively for the organization. Reflecting this change in the relationship between organizations and workers, recent studies on organizational design are focusing on creating an environment for open collaboration, such as an interface for communication and protocols or a process for task distribution and integration. In this context, platforms can be addressed as an organizational environment, and it implies that the opportunities for designers to contribute to organizational design are expanding.

First, designers can bring new perspectives to organizational design. Attitudes towards devising an optimized solution to a problem and designer methodologies to find a creative solution are beneficial for organizational design for open collaboration. For example, the self-organization mechanism of social insects was used as inspiration for organizational design in this research. Getting inspired by nature is one design approach with a long history, and many nature-inspired design methodologies have been introduced in the design research field. However, most previous studies suggesting the potential of biomimicry for management are based on theoretical investigation rather than empirical verification (Mead, 2014). To promote nature-inspired organizational design as a pragmatic approach for constructing or improving organizations, further studies to provide an organizational design methodology for practical applications and to validate its effectiveness would be necessary. To this end, designers are expected to contribute to deriving design directions from natural principles and executing the solutions (Kennedy, Fecheyr-Lippens, Hsiung, Niewiarowski, & Kolodziej, 2015).

The other task for designers concerns the application of a self-organization mechanism. In the process of developing a framework based on self-organization phenomena, the significance of intrinsic parameters was recognized. With regard to intrinsic parameters, the effect of motivational factors on human behavior is different from that of the behavior of non-human organisms. In addition, human beings have a higher level of autonomy in reaction to external stimulation than social insects, which means that a protocol that is designed based on insufficient apprehension of the intrinsic characteristics of actors has the risk of resulting in totally different behavior patterns from the expectations. Accordingly, a fundamental understanding of motivational factors and their influences on behavior, especially collaborative behaviors, are needed. The differences of needs and motivations between different groups of actors should be clearly identified and applied to the platform design process. Considering the traditional role of designers, i.e., extracting implicit user needs and providing users with satisfying products, we believe that designers are apt to design an external environment that
attracts the spontaneous participation of actors. Nevertheless, additional expertise, such as system design and organizational design, is required for designers to take part in platform design.

**Conclusions**

In this research, an organizational design framework for designing an open collaboration platform was developed based on the self-organization mechanism of creatures in nature. In particular, the communication patterns that can be observed in nature, such as the feedback effect through local interaction and stigmergy, show how the information system can be improved to enable efficient communication and collaboration between the actors. Additionally, the application of self-organization phenomena to organizational design stresses the importance of consideration on the intrinsic characteristics of participants in organizational design, which means that designers have more opportunities in organizational design than before.

The practical contribution of this research is the introduction of a conceptual foundation for open collaboration platform development. The framework inspired by self-organization encompasses the design issues that were suggested in the previous studies on organizational design for open collaboration. The analysis of the existing platform using the framework also implies that this framework could be a guideline for the integrated platform design approach and contribute to improving platforms. Improvement of the open collaboration platform would encourage the participation of diverse actors in the process from problem identification to solution implementation and contribute to establishing participatory culture in social innovation in the long run.

Regarding the academic contribution, this research calls for interdisciplinary collaboration to promote innovation. In this research, biological phenomena were investigated to generate inspiration for organizational design, which has mainly been handled in the management field. Additionally, the potential contribution of designers in the application of the self-organization mechanism to organizational design for the open innovation platform was suggested. Accordingly, collaboration among researchers in biology, management and design are necessary for further progress in this research. To devise a new organizational design to support the novel innovation strategy based on advanced ICT, the approach to design an organization also needs to evolve. In this context, this research implies that unfamiliar knowledge and perspectives of different disciplines could generate inspiration for innovative solutions.

Nonetheless, the limitation of this research is that the framework was developed using a theoretical approach. To complement these limitations, the effectiveness of nature-inspired organizational design needs to be examined by empirical validation. For future work, the tools and processes to design the open collaboration platforms will be developed based on this
framework, and tested through practical applications.

Abstract
The more society gets complicated and developed, the more demand for various products. As a result, we are living in a flood of various products. However, considering how people consume and use products in their daily life, it is not difficult to find people transforming, changing the original purpose or adding value to existing products instead of buying new ones. This phenomenon has been defined as everyday design. In a sense that everyday design provides a better understanding of actual uses in real context, it deserves to be studied. Therefore, this paper attempts to figure out an underlying mechanism of everyday design. For this, a conceptual framework was developed, whose focus was on what triggers everyday design, what goals are set, and how a product is transformed. The conceptual framework was validated with a photographic inventory of users’ everyday design in our daily life. The conceptual framework could provide a better understanding of everyday design in a systematic way. If it is considered in the product development process, it could contribute to an increase of use satisfaction as well as sustainable design. The limitations and a further study are discussed at the end of the paper.

Keywords: everyday design, unselfconscious design, hacking, product design, sustainable design

As a society gets more developed, product demand for proper purposes also increases and various products appear in the market to satisfy the demand of consumers. As a result, we are living in a flood of various products these days. It is no exaggeration anymore to say that we are buried under all kinds of products. Interestingly, this phenomenon appears more in developed countries than in developing countries: i.e. there are more diverse products designed particularly for a function in developed countries than in developing countries. For instance, there are a variety of kitchen appliances ranging from electric whisk and potato masher to vegetable peeler and silicon spatulas in Western European countries. However, only a knife and a wooden spoon are used to prepare food in a kitchen in the 3rd world. Because of such lack of resources in developing countries, it is not difficult to find people transforming, changing the original purpose or adding value to existing products (see the left example of Figure 1). This way of transforming existing products for different purpose is sometimes observed in developed countries as well. A good example is that there are people who hack IKEA products for their own pleasure (see the right example of Figure 1).
Historically, the phenomenon was explained first with the concept of unselfconscious design (Alexander, 1964). According to his notion of unselfconscious culture, people unconsciously design things for goodness of fit. As the unselfconscious process learned informally and iterative process over time, this culture existed before the advent of professional design and the culture is still shown in our everyday life. Dix (2007) supports creative misuse and suggest appropriated design of guidelines. Related with appropriated design, bricolage describes the practice that people invent appropriate artifacts immediately within everyday settings (Louridas, 1999). Also, DIY communities and amateur communities such as IKEA hackers have shown their appropriated redesign in specific their context (Rosner & Bean, 2009). This appropriation is in line with Alexander’s unselfconscious process. Kim and Lee (2014) defined this term as ‘everyday design’ by defining a user as a more creative and proactive agent. Emphasizing the role of user, they addressed that the behaviors of people to designed products are not the result of design but the production of creative processes. Brandes and Erlhoff (2006) also introduces non-intentional design with cases of creative uses of products by users, not by designers. As many terms have been used to denote this phenomenon, the term everyday design is used in the study to emphasize the quotidian nature of this activity.

Considering discrepancies between expected context by designer and real context by actual users (Crilly, Maier, & Clarkson, 2008), bottom-up approaches have been increasingly emphasized and designers have adopted co-design approach for understanding and applying users’ needs and ideas. Ihde (2008) and Redström (2006) emphasized the consideration of unintended uses and use of unintended users in product development process. In a sense that unselfconscious design provides designers with real context of users in interaction-oriented process and designers can get inspired with actual users’ redesign (H. Kim & Lee, 2014), an understanding of this phenomenon could help to increase the satisfaction of users. Furthermore, it could also contribute to more sustainable design because people tend to use satisfied product longer. After Blevis (2007) introduced the term sustainable interaction design, many studies propose material effects of sustainable design. His focus was on the linking between invention and disposal, and finding opportunities in reuse product and materials. Odom et. al (2009) tried to understand the motivation or preserving and discarding artifacts. These studies provide a useful source of underlying framework of sustainable design.

When users encounter with a product, users can have information of a product through touch,
vision, smell, sound and action. Based on these information, users judge a product and utilize it as a solution. This explains solution-based design approach (Helms, Vattam, Goel, Yen, & Weissburg, 2008; Kruger & Cross, 2006). A good example is an abandoned antique table sewing machine that is reincarnated as a tea table for a café. As opposed to solution-based design approach, problem-driven design approach first considers understanding the a given problem with information and knowledge. The emphasis is on defining the problem, and then searching a solution. For instance, people put a pen between pages of a book to bookmark (Figure 2).

![Image](image-url)

Figure 2: Examples of design approach. An antique table by solution-based design approach(Left). A bookmark by problem-driven design approach(Right).

Consumers purchase and experience a product for particular goals. This goal is the key to understand why people do everyday design. Based on previous theories of user experience, Kang et. al (2016) redefined five dimensions of user experience: sensory, instrumental, episodic, value, symbolic experience. Sensory experience is related with the human sensory system, the sensorial component of experience. We like the smooth texture of a fountain pen, and the beautiful shape of a chair, for instance. Instrumental experience is evoked from how easily and effectively instrumental goal is achieved. For example, some people like a coffee machine because they can save time and effort. Episodic experience is related with users’ memories or episodes with a product. A father likes the necktie given by his beloved daughter for the first time in his life. Value experience is related with users’ value, such as self-improvement, personal and common benefit. Some people love organic cosmetic because of environmental sustainability. Symbolic experience is generated from symbol or representation that a product socially stand for. For example, some people love Nike’s running shoes because it represents young, energetic and urban health lifestyle (Figure 3).
From the perspective of recycling and habits, ways of reuse are presented by users. The principle is on reuse techniques combined with other prosperities to understand reuse composition of users’ redesign: Reuse, Remake, and Remanufacture (S. Kim & Paulos, 2011). Reuse is defined that use of original products for other purpose then originally designed by simple operations. A good example is a lightbulb vase, which becomes a small vase for fishes. Remake refers to changing the functions of the original products with simple crafting and manufacturing. For example, to give a personal identification, a key chain is made of keyboard keys with alphabets. Remanufacture means a complete reconstruction of the original products with complicated ways with tools. For instance, can phones work like a phone through thread (Figure 4).
Although previous studies have emphasized the importance of understanding user’s behavior in real context through the phenomenon of everyday design, there are no studies dealing with a holistic framework of how everyday design happen and what reasons motivate people redesign original products in a systematic way. In order to get a complete overview of all aspects involved in this everyday design, a conceptual framework was developed and is presented in Figure 5. The conceptual framework for this study consists of four agents working in unselfconscious design: a user as a principal agent interacts with product A under context A, and he/she redesigns product A to product A’ for a best fit in context B. In the process of everyday design, three steps are involved: approach, goal and transformation. Approach refers to the trigger of unselfconscious design, and there are problem-driven and solution-based approaches. At the stage of goal, he/she targets expected experiences with his/her everyday design. Finally, transformation is applied to the original product in order to achieve the goal. This ends up with product A’.

Therefore, this study, as an exploratory study, attempts to empirically reveal if the conceptual framework of everyday design works in practice, under a premise that every user is a designer and they creatively and appropriately redesign and transform products. The objectives of the study include what triggers everyday design, what goals are set, and finally how it is transformed. In this way, this study could contribute to bridging the gap between intended use made by designers and actual use made by users and it could lead to sustainable design with products people love to use.

1. METHODS

This study has a characteristic of exploratory study to figure out the underlying mechanism of everyday design. Thus, a selection of everyday design cases was made among many of products in our everyday life.

1.1 Sample

For sampling in the study, two researchers spent two months hunting cases of everyday design in our everyday life. A total of 30 cases was collected through the method of photographic inventory collection (Desjardins & Wakkary, 2013).
1.2 Data analysis

Three researchers were involved in the analysis phase, whose background was industrial design and whose experience in design was more than five years. The photographic inventory was analyzed in terms of approaches, goals, and transformations. Because the cases were collected by taking photos without involving their users, the interpretation of the cases was made purely based upon the expertise and experiences of the researchers. With the interpretation, the cases were categorized in terms of similarity (Figure 6).

2. RESULTS

In order to figure out the underlying mechanism of unselfconscious design, the 30 photographic samples were analyzed in terms of approaches, goals and transformation and categorized based on similarity.

2.1 Products used for everyday design

Everyday products with low technology took up all the cases, which ranged from bricks and dishes to chair and hairclip: a person made a door step by laying bricks in front of the entrance, a broken dish was used for an interior item hung on the wall, a person was carrying a heavy bottle of liquid with the chair with wheels. A hairclip was used to stop up the plastic bag with breads (Figure 7).

In the process of redesigning products from the original ones, there were two types of everyday design in terms of functionality. One is that primary functions designed by designers for a context are completely changed to fit for another context. For instance, a fire extinguisher...
functions as a door stopper although its primary function is to extinguish fire. Another good example is that an ice cube mould is used for organizing pens on the desk (Figure 8).

Figure 8: Examples of primary function change: fire extinguisher (left) and ice cube mould (right)

The other is that a product is used for another context utilizing the primary functions given by the designer. For example, a plastic basket for cookies is used for putting fishes in. Clothes peg is also used for tying up electric cables of computer and its accessories (Figure 9).

Figure 9: Examples of maintaining primary function: plastic basket (left) and cloth peg (right)

It was shown that primary functions were changed in 57% of the cases while primary functions were maintained in 43% of the cases.

2.2 Approaches of everyday design
As previously described, there are two approaches by which people are triggered in the context of everyday design: problem-driven approach and solution-based approach. According to the analysis, problem-driven approach took up 67% while solution-based approach 33% among 30 cases (Figure 10)
A good example of problem-driven approach was that people use the back of a chair as a rack when they need to hang wet towel. The iron gate of the outside is an example of solution-based approach. The iron door became a table used in a café (Figure 11).

Figure 11: Examples of problem-driven and solution-based approaches: chair for hanging a towel (left) and iron door used as a table in a café (right)

2.3 Goal of everyday design
The five dimensions of positive user experience were used to identify goals of unselfconscious designs in the study. The most often mentioned goal was the instrumental experience (90%) (i.e. functionality, usability and efficiency) among 30 cases (Figure 12). For example, a plastic basket with many holes was used for drain remained water of dishes and bowls after washing dishes. This was followed by sensory experience (63%). A good example is that a Korean traditional pot used for making soybean paste or soy source became an umbrella stand in a company. Value experience took 37% of all the cases. For instance, packing materials for protecting fruits during transportation was used to cover plant pots. Episodic experience was mentioned in 17% of all the cases as goal of everyday design. A traditional winnowing basket that could be worn when children wet their beds was used as an interior item in a restaurant. Symbolic experience took up 17% of 30 cases. A good example of this goal is a sake lover who transformed a pack of sake to a case of tissue paper on the dining table. Figure 13 shows the examples with pictures.
2.4 Transformation for everyday design

In terms of the ways to transform the original products for everyday design, three dimensions such as Reuse, Remake and Remanufacture were adopted for the study. Remake cases took up the largest number of transformation with 50% of all cases (Figure 14). For example, a billiard cue redesigned as a pointer by making a hole on the billiard cue. Reuse cases had similar ratios with Remake ones (43%). A hairpin used for a plastic bag clip is a good example to explain the reuse transformation. Remanufacture cases took up only 7% of all the cases. For instance, a paper of receipt became the price tag of a book. Figure 15 shows the examples in pictures.
3. Discussion and Conclusions

All the 30 cases collected for this research were products with low technology. A possible explanation is that the type of products would be perceived as easy and comfortable to transform considering the simplicity and the price. It might also imply that low technology products could be more sustainable than high technology products because the type of products mainly appears in everyday design. In the study, it was also revealed that transforming the primary function for best fit in a context is more observed than maintaining the original functions of a product in the context of everyday design. The implication of the finding is that people might have creative inclinations dealing with redesigning their own products. Perhaps, it might have to do with their concerns about sustainability. Let say, they might come to be creative thinking again and again of how to utilize their products instead of discarding.

In terms of trigger to everyday design, problem-driven approach was twice more than solution-based approach. In the context of everyday design, it seems that people see their everyday products as alternatives to tackle problems they suddenly meet unless there are proper solutions to the problems. The goals that people redesign a product themselves could be explained with the five dimensions of positive user experience. Instrumental experience was most frequently mentioned for unselfconscious design. This result is in line with previous studies in which instrumental value explains the major reason of negative user experiences with products, and the value was ranked as most important factor that influences positive user experience (Kang et al., 2016; Kim & Christiaans, 2014). Interestingly, value experience was ranked higher in the study of everyday design than in the study on positive user experience.
with products. It might imply that the value of sustainability is taken into consideration more in everyday design. There are three types of product transformation for everyday design. The number of Remake cases were the highest and this was followed by Reuse cases. Remanufacture cases were least reported. This result corresponds with the findings of Kim and Paulo’ study (2011). The main difference between his study and this study is technology level of the cases used in the studies. In their study, e-waste which refers to high technology products were used while in this study, low technology products in our everyday life. Considering this difference and the similar results between two studies, it seems that the level of technology applied to products would not influence the way of transformation in the context of everyday design.

**Design implications**

This study tried to empirically evaluate if the conceptual framework of everyday design works in reality. The results show that everyday design could be explained better with the conceptual framework. Through the conceptual framework, the phenomenon could be better understood in a systematic way. If a better understanding of actual use of our everyday products in actual context is made in the product development process, it is expected that products can be better designed in a way to reduce the gap between intended use by designers and actual use by users and per se to increase satisfaction with products. In this way, this study could contribute to more sustainable design because people tend to possess longer if a product deliver positive user experience through satisfaction.

**Limitations of the study**

Nevertheless, the study has limitations that include sample size and location. It is not sufficient to generalize the findings only with a total of 30 cases. And the cases were collected only in South Korea. As a creation activity, unselfconscious design might be influenced by culture. In addition, the goals of redesign activity were identified not by interviewing with the users but by the interpretation of researchers involved in the study, which might be biased. Therefore, a follow-up study is planned with a number of everyday design cases including diverse locations as wells as interviewing actual users.

**Acknowledgement**

We especially thank Sorin Kim who helped much collect the data of the study. This work was supported by the ‘Promotion of Special Design-Technology Convergence Graduate School’ of the Korea Institute of Design Promotion with a grant from the Ministry of the Trade, Industry & Energy, Republic of Korea (N0001436).

**Author Biography**

**Soyoung Kim**

Soyoung Kim is a doctoral researcher at Emotion Lab, Ulsan National Institute of Science and Technology (UNIST) in Korea. She earned a Bachelor of Arts at Ewha Womans University and a Master of Engineering at KAIST. Her doctoral research is a new use of everyday products. She focuses on sustainability and emotion in the human-product interaction.

**Kwangmin Cho**

Kwangmin Cho holds a BSc and MSc in integrated industrial design and engineering system design from UNIST. He likes creating something with various tools and materials. His interests are in figuring out design problems in public space and improving them in order to provide positive
experiences for people.

Chajoong Kim
Chajoong Kim is an associate professor at the School of Design and Human Engineering, UNIST, South Korea and the founder of Emotion lab whose focus is on research through design making in the school. He holds a Master of Science (design for interaction) and doctoral degree (product experience) from the School of Industrial Design Engineering, Delft University of Technology in the Netherlands. He was a mechanical engineer and with his engineering knowledge and experiences, he has combined design and engineering in developing products and services. His research interest includes product experience, usability, human-product interaction, user diversity, cultural differences in design and cognitive aspect in usability. His research has been published in peer-reviewed journals such as International Journal of Design and Journal of Design Research. He has also conducted many design projects with companies such as Philips, Bang & Olufsen, Samsung, LG and Fokker Elmo.
Collaborative design education with industry: Student perspective by reflection

Abstract
This study suggests that student reflection on academic and industry collaborative projects can enhance student’s understanding on the design process to solve live industry problems. It contributes to the body of design literature to support students learning of explicit and implicit knowledge (Boling et al., 2016; Land et al., 2016; Salama, 2015). A 2017 learning-by-making (LBM) unit in the School of Architecture and Design, at the University of Tasmania, Australia, developed a unit for students to collaborate with Neville Smith Forest Products Pty. Ltd. (NSFP). NSFP is a local Tasmanian timber product manufacturer who currently stockpiles out-of-grade timber that has limited market applications. Undergraduate design students from second and third year Furniture, Interior and Architecture degrees collaborated with NSFP to value-add to their out-of-grade resource in the LBM unit. A series of design challenges, observations of industry practice and access to out-of-grade timber from NSFP exposed students to live industry problems and provided them the opportunity to build professional design skills. Students reflected on the collaborative LBM unit in a reflection journal, which was used to provide evidence of their learning experiences. The collaborative environment between academia and industry allowed students to acquire an understanding of timber product manufacturing that helped them develop empathy towards the industry problem and influence the development of new products. This study presents how student reflections influenced a change in their design process as they progressed through sequential design challenges to address an industry problem by adopting Valkenburg and Dorst (1998) reflective learning framework.

Keywords: Academic-Industry collaboration, learning-by-making, live project, design process, reflection.

The School of Architecture and Design, University of Tasmania, Australia, has a reputation for its learning-by-making (LBM) classes having conducted over 100 projects, over 20 years (Burnham et al., 2015; Salama, 2015; Carpenter, 2011). LBM units are designed to expose students from all design disciplines to real design work and allow them to explore design practice through thinking, making and reflecting on these processes. LBM units focus on live community or industry problems and facilitate the process of design from ideation through to fabrication whilst collaborating with peers in groups and a client. This study presents the change in student design process after participating in design challenges to address an industry problem. The change in process was substantiated through student reflections expressed both explicitly in a journal and tacitly through observations. These reflections demonstrated students transformative learning from design students to novice designers with industry experience.
In February 2017, a summer semester LBM unit was offered to School of Architecture and Design students for them to collaborate with Neville Smith Forest Products Pty. Ltd. (NSFP)—a Tasmanian oak hardwood timber product manufacturer who supplies local, domestic and international appearance markets. NSFP currently manufactures a diverse range of Tasmanian oak products and flooring profiles for interior applications. Their current manufacturing process produces a series of Australian standard graded timber products, as well as out-of-grade products that fail to comply with *Australian Standard 2796.2* (2006). This material has limited secondary product applications thus generating a stockpile of low value timber with little market demand. A brief was developed for students to design, develop and prototype new products utilising NSFP current stockpile of out-of-grade timber. The aim was to value-add to the resource and thus provide new market opportunities for NSFP. The NSFP design challenge presented in this study provided students with a live industry problem that gave them experience in identifying an opportunity to develop new products and to recognise the expectations that industry has for commercialisation.

**Literature Review**

Current literature claims pedagogical design exercises that present opportunities and experiences to students such as industry project-based learning or live projects are key threshold concepts for students to transition from student designers towards competent and confident design professionals (Boling et al., 2016; Burnham et al., 2015; Blumenfeld et al., 1991; Hokstad et al., 2016; Osmond & Turner, 2010; Salama, 2015).

A characteristic of the assessment and activities associates with the transitional moments where students appear to progress through the threshold concept, appear to be problem-based, experimental, related to work and ‘real-world’ design activities and often involve group work; in other words there is a focus on ‘doing as learning’ (Osmond & Turner, 2010).

There is no denying that real-world design activities differ from typical academic studio-based activities given the difference in industry and academic approach to design projects and design processes (Hokstad et al., 2016; Kim, 2016; Kotlarewski et al., 2016; Salama, 2015). In circumstances where industry seeks to engage with design and designers, the intention is to create value that can help gain a competitive advantage (Fonseca, 2016; Gemser & Leenders, 2001).

Where possible, it is argued that student exposure to real-world design activities is a key experience and opportunity that can assist student’s transition through threshold concept learning (Burnham et al., 2015; Land et al., 2005; Land, Meyer & Flanagan, 2016; Meyer & Land, 2005; Meyer & Land, 2006). It is common for students to become frustrated, lose confidence or stuck in a cycle of the unknown early in design exercises. It may be better for students to experience such difficulties in a controlled environment earlier in their degree to learn how to overcome such difficulties and therefore learn how to approach challenges in future learning and employment opportunities. Student reflection upon these difficulties, opportunities and experiences in a reflection journal is an integral learning activity that demonstrates evidence of student learning (Ellmers, 2006; Moon, 2004; O’Connell & Dyment, 2006; Clifford, 2002; Webster, 2004).

The process and reflection assessment task encourages the student to identify critical incidents from the design process and contextualise them within the outcomes of the
final design artefact. This is significant in that the student assumes responsibility for identifying important moments of the design process there by encouraging them to be independent learners (Ellmers, 2006).

A study by Valkenburg and Dorst (1998) was influenced by the work of Schön (1983). They indicate Schön’s (1983) work has proven itself useful for describing design activities and focus their attention to describing reflective practice in team designing in figure 1. They illustrate four different activities that design teams exercise as the mechanism of reflective practice.

![Figure 1 The mechanism of reflective practice; the four design activities and their interplay (Valkenburg & Dorst, 1998)](image)

The four activities, naming (identifying important parts of the design task), frame (focusing on the context), moving (generating ideas), and reflecting (explicit documentation of actions) are presented as a flow diagram. Valkenburg and Dorst (1998) use this flow diagram in their study to present reflective practice in team designing, compare two case studies and quantify the time spent by design teams in each activity. Mapping the mechanism of reflective practice was applied to this LBM study to indicate the transformative learning experience that students gained from the industry project-based unit. The overall mapping of the student reflective practice is illustrated and presented in the discussion on this study.

**Research Methods**

Observations of students and reviewing student reflections were used to substantiate transformative learning in the LBM unit. These research methods provided evidence that students were developing their ability to approach design challenges both explicitly through critical analysis of their key learnings and tacitly through making, as an individual and a group member. The LBM unit presented in this study ran intensively over 10 days, consisting of 13 students divided in five groups.

This LBM unit exposed students to three design challenges that gradually introduced new variables in a controlled environment to provoke threshold concept learning. The first design challenge—ran on day one—was a short three hour activity used to expose students to the overall design expectations of the unit. In three hours, students were expected to follow a set of rules to design and prototype a scaled cardboard product. While students worked,
observations of the students design process and design skills where noted and recorded as photographs by the lecturer. Students were also encouraged to record and document their design process and product developments—typically as photographs and sketches—throughout the design challenge. This evidence was later compiled in student’s reflection journals to highlight critical thinking and key learnings.

The second design challenge—ran on day two—was another short three hour activity, again bound by a set of rules to design and prototype a scaled timber product using timber off-cuts. Before the second design challenge started, students were given a tour of NSFP mill to observe the manufacturing process of timber products. The exposure to manufacturing constraints was intended to add another variable to the student learning experience to assist the development of their design process and timber product. It was expected that the tour of the mill would highlight key industry constraints such as production lines, resource management and product handling.

The third design challenge ran from day three to day 10. This design challenge gave students more time to move through the design process and develop more products with timber that NSFP specifically supplied. This challenge presented a live industry problem to the students as they had to meet a dead-line, consider implementing the product into NSFP production line and develop a range of products with the specific timber supplied.

The gradual increase in responsibility of students was intended to build student design competencies and prevent overwhelming the students with a live industry problem at the commencement of the LBM unit. The controlled exposure to design activities was used to review their explicit individual journal reflections and to observe evidence of these developments in students tacit knowledge in response to the industry brief, as well as their learning.

**Discussion**

The opportunity and exposure to industry that students gained from the LBM unit helped them develop valuable insights that assisted individual reflection and the development of tacit knowledge on the underlying industry problem, the design process and their design skills. Outcomes from these key areas helped students develop design competencies that assisted their approach to the design challenges in the LBM unit.

Design challenges one and two encouraged students to be creative, try something new, fail quickly, reflect on the outcome and then further develop the idea. This process was both sequential and iterative. The first design challenge was a product design cardboard activity conducted on day one. Students had three hours to design, prototype, develop and reflect on their process, product, and group collaboration. The design challenge was broad yet constrained by rules, giving the students the freedom to design any product—in groups of two and one group of three—at 1:4 scale, using only cardboard. The restriction to cardboard only, was to challenge students to develop a product that was aesthetically pleasing, structurally capable of holding 5 kg and could be easily manufactured within the design studio environment. Figure 2 depicts the student reflective process through the cardboard design challenge.
As observed during the first design challenge and shown in figure 2 students were inevitably confronted with the cardboard design challenge and became confused. In–line with Valkenburg and Dorst (1998), students approached the design challenge by first identifying the important aspects of the activity (naming): what am I doing? They then began framing the context of the design challenge: to design and develop a product out of cardboard. A lack of understanding the relevance of the cardboard design challenge limited student confidence and added to the task frustration that led students to fail to let go of the first concept they produced (moving): generating an idea. At the end of the challenge, students presented their product and reflected on the journey (reflecting). Initial reflections of the design challenge as anecdotal evidence was: What was the intention of the challenge? Why are we designing a product with cardboard when the unit is about timber product development? In response to the first design challenge, students identified their lack of exploration and conservative approach was a constraint to developing a cardboard product that taught them something new by making. Explicit student reflections later highlighted:

- Today helped me realise the importance of failing early and not becoming attached to the point that it prevents further innovation and critical thinking.
- Too much time was spent finalising the design, therefore when it came to making/testing we were rushed for time and had little time for corrections.
- It is possible to over plan. Continuing to design without trial is a pitfall.

The second design challenge was to develop a product with NSFP timber off-cuts. Prior to the design challenge, students were given a site tour of NSFP where they observed the management of green timber and processing of dry timber to manufacture interior fit-out and flooring products. Students observed NSFP facilities and manufacturing processes and began identifying opportunities to implement new product manufacturing lines for out-of-grade timber. After the site visit students were briefed on the second design challenge. They again had three hours to design a product, prototype and develop it and reflect on the process and product development. Given the students had a similar experience the day before they were equipped with the knowledge and expectation of the challenge. Unlike the cardboard design challenge, student groups were allowed to use additional products such as glue and fasteners to manufacture their 1:4 scale product out of timber-off cuts. Figure 3 depicts the student journey through the timber design challenge.
An obvious difference existed between the first and second design challenge. Students were given background knowledge of NSFP timber processing and product manufacturing through the site visit and were aware of the expectation to generate a series of concepts. This change in structure allowed the students to “frame” the context of the project before “naming”. Students immediately began generating ideas (moving). Observations noted that students were better equipped with experience and expectations from the first design challenge. Students even combined concepts to develop hybrid products that incorporated a series of features and functions. The experience attained from the previous design challenge through reflection gave the students the courage to try something new and accept that the first concept that they produced was likely to be discarded and forgotten or developed into another concept generation. In relation to the timber design challenge students noted:

- Great process of design development today. The product field opened up many more ‘potential use’ opportunity’s rather than narrowing the options (as it felt like I did on day 1). I believe I can already feel an increase in design flow and critical thinking since yesterday’s cardboard challenge.
- Making/experimenting with our own ideas in the first prototypes we were able to bring our knowledge together. By bringing my idea about using the high feature knots for natural light and hangings, we were able to build on this for prototype two. From today’s design challenge and the visit to NSFP I started to realise [that] the natural aesthetics [of] these high feature products have a future in interior lining [products].

By day three, students had a better understanding of the type of process and product developments that were expected. Each group of students created a return brief that highlighted their perspective of NSFP, the industry problem, opportunities they considered worthy of exploration and how they proposed to address them (framing and naming). Again, students immediately began exploring concepts by making (moving). Observations noted students typically spent a day developing each concept. Between concepts students would confidently and naturally reflect on the product and process. This reflection was later documented explicitly in their reflection journals (reflecting). Figure 4 illustrates the process the students used to satisfy the NSFP design challenge.
Since the first design challenge the students expanded their design skills and ability to critically reflect on their process and product development. They were more confident with their concept execution and presented their work professionally to NSFP. More time was spent making and reflecting during the third NSFP design challenge as the students had learnt what the expectations of the academic studio outcome should resemble and what industry collaborators desired. The progression through figure 2-4 demonstrated that the students increased their ability to develop concepts beyond the initial ideation stage and were able to reflect on their practice. The act of reflection allowed students to justify their process and product developments confidently which assisted with their concept deliverance to NSFP. Final student reflections highlighted:

- I have truly enjoyed the process of learning by making over the course of 10 days. I believe my ability to develop, analyse and critique both myself and other student’s designs has progressed greatly.
- It felt good to produce something that would work in a commercial situation as opposed to only seeking budget solutions.
- Overall, the unit has me thinking so differently about how I go about my [future] work.
- I personally found this unit worked really well from a collaborative point of view.

At the conclusion of the design challenges, NSFP representatives were present during the student presentations. While the focus of this study is not the student product outcomes, the use of tangible products proved useful to demonstrate student creativity and the LBM process to NSFP. This was an opportunity for students to engage in their groups with NSFP for feedback. This was also an opportunity to demonstrate the capacity of student skills to NSFP. This constructive reinforcement of industry engagement was important for the students to build a relationship with NSFP and to build student confidence in the lead up to the main NSFP design challenge. The same could be said for the experience gained from industry with design students, as they typically do not engage with designers.

**Research Contribution**

Student reflection on this academic and industry collaborative project demonstrated
enhanced student willingness to explore innovative timber design outcomes by using a product design and development process to solve a live industry problem. Initial design challenges that were simple in nature yet challenging enough to demonstrate the design process and the importance of understanding and addressing the design problem were critical to prepare the students for the main project. By resolving the design process through modelling and making, students had a better success with the tectonics as they are not removed from the abstract world of paper or digital modelling (Burnham et al., 2015; Hokstad et al., 2016; Salama, 2015; Wallis, 2007). Furthermore, student exposure to real-world practice in an industrial context substantiated this, as did involving key industry partners in student presentations and reflections. From the first to third design challenge, student’s confidence and their ability to make informed decisions without guidance from studio lecturer increased.

Students gradually become self-motivated and driven to develop their ideas by prototyping and actively reflecting on their work. In addition to studio observations, explicit reflections in student journals provided evidence of transformative learning. The act of making followed by the act writing allowed students to better identify what they had achieved, what did not work and why, and justified how well they had address the industry and design problem. The reflection journal ultimately outlined the process that the students employed to development, prototype and refine their design outcomes. Reflections on sequential learning outcomes from design challenge one, through to three also helped the students prepare for the next design challenge and to address the unit outcomes.

Future studies

This study reinforces the design literature that collaborative student learning environments between industry and academia can assist students build design competencies and therefore prepare them for industry employment. However, previous LBM studies by Wallis (2005) and Moon (2004) on reflective learning suggest difficulties are experienced in transferring knowledge to another educational context or workplace. This indicates the need for further research and developing ways that allow students to develop greater independence from educational contexts. Another limitation in this study was not all students explicitly communicated their new knowledge attained from the LBM unit in their written reflections. This suggests that while the opportunity was presented through the LBM unit, it may not always be immediately enacted by students who know how or why to reflect on these events. Other mediums of capturing student transformative learning could be explored such as daily video reflections and time-lapse of development work in studios and workshops. It would also be beneficial to conduct future studies with the same students prior to their graduation to see how they continued to develop their approach to industry projects as they gained more experience throughout their degree. There is also an opportunity to consider what impact student exposure to a global industry in two different context has on their professional development. Furthermore, incorporating and testing different methods to engage students in reflecting—taking into account the vexed issue of the influence of assessment—could be explored.

Conclusion

Collaborative learning environments between industry and academia exposes design students to live industry problems that can help them develop new processes and built
confidence to approach design opportunities in the real-world. In this study, students generally improved their process and approach to design challenges as they progressed through the three design challenges presented. Key to this improvement was individual reflections by the students that highlighted new knowledge attained from the experiences. Student reflections documented in journals and observations of students in the LBM unit demonstrated evidence of design developments and an increase in design competence as students became more independent and self-motivated to develop products to satisfy an industry problem. This was illustrated by incorporating Valkenburg and Dorst (1998) mechanism of reflective practice against student’s transformative learning process development. Industry collaboration also added to the students learning process as industry typically grounded the students work to ensure the outcomes were feasible and commercially relevant to the business. The authors of this study hope the findings in this research to be useful for developing student learning experiences and may help prepare students for industry employment after their studies.

**Author Biography**

Dr Nathan Kotlarewski
Nathan is a Postdoctoral Research Fellow from the ARC Centre for Forest Value, at the University of Tasmania. He is an Industrial Designer with a background in Timber Product Design and Development. His research delivers new knowledge on Australian plantation hardwood timbers in order to develop innovative applications with industry partners for the built environment.
Dr Louise Wallis
Louise is Lecturer at the School of Architecture & Design at the University of Tasmania. She is active contributor to design learning and teaching research in architectural education as evidenced by her roles in national teaching grants (2006, 2009 & 2011) in Australia. Her published work focuses on influence of Higher Education Institutions on architectural studio models, instruction methods and the effectiveness of design/build studios.

Michael Lee
Michael is a Senior Technical Officer for the Centre for Sustainable Architecture with Wood (CSAW) at the School of Architecture & Design, University of Tasmania. He has years of experience in the timber industry, predominantly in senior testing, technical and project management positions. Michael coordinates the daily running of technical aspects of CSAW's Tasmanian Timber Promotion Board and provides a vital link to the timber industry, general public, designers and architects.

Associate Professor Gregory Nolan
Gregory is an Associate Professor at the University of Tasmania's School of Architecture and Design, and is the Director of the University's Centre for Sustainable Architecture with Wood (CSAW). He has published in books, journal articles, and conference publications, all with a key focus in sustainable design, environmental aspects of construction and building performance, as well as the broader use of renewable materials in the built environment.
Gregory is an experienced research manager and has directed and conducted numerous industry funded projects.

Megan Last
Megan is a marketing professional, who at the time of the LBM unit was the Marketing and Product Development Manager at NSFP. She currently runs her own timber company working with industry to develop new products and markets connected to out-of-grade timber for the purpose of fully utilising and adding value to Tasmania’s forestry assets.
Study of the implementability of tactile feedback while operating touch panel device - From two directions of efficacy & feasibility -

Jien Wakasugi, Kyoto Institute of Technology, Kyoto, Japan, b3124503@edu.kit.ac.jp
Masayoshi Kubo, Kyoto Institute of Technology, Kyoto, Japan, m-kubo@kit.jp

Abstract

In a few years, the number of apparatuses with touch panel displays like smartphones will increase. People who are visually impaired, hearing impaired and disabled can use tactile feedback for receiving incoming communications. However, opportunities for tactile feedback applications are limited.

Our hypotheses follow: as there are haptics patterns suitable for use cases, we will design haptics samples of tactile feedback and inspect their effectiveness. This study focuses on haptics patterns showing a relationship between the user’s impression and various use situations. Previous studies have been insufficient, so our target subjects inspected a limited number of objects.

This study consists of two inspections:

1) We collected various haptics patterns that users had defined and analyzed the first inspection. For the next inspection, we manufactured a smartphone prototype. We matched the impression of eight haptics patterns types that we got from the subjects in the first analysis with different situations and tested various replies.

Tests were repeated and recorded for various situations. As different haptics vibrations were added to emails, we inspected whether subjects could distinguish a difference in their meanings. Thus, we added different haptics patterns that corresponded to various situations. We concluded the hypothesis was effective for subjects. We could inspect the hypotheses in relation to subjects’ impressions of the haptics pattern.

2) Additionally, we obtained different results between elders and youths. Consequently, we suggested design guidelines for the new tactile feedback of the smartphone application. We suspect that haptics will be possible for a variety of interactive designs.

Keywords: Haptics, Emotion, Situation

1. Research background

In recent years, the number of devices equipped with a touch panel on a display typified by a smartphone has increased. Although it has made it possible to perform intuitive
operation, it has been conventionally pointed out that a user interface without a physical clue becomes a cause of erroneous operation. On the other hand, effective application of haptic feedback, which is "tactile (vibration) stimulus issued in line with investigation" is expected.

Tactile feedback is used today in incoming phone calls, games and other situations. Tactile feedback is also provided for inputs used in gestures such as touch, pinch, swipe, etc. in touch screen devices including smartphones. However, existing haptic feedback does not have many patterns, and opportunities to use are limited. However, in reality there should be suitable patterns according to the situation, and it is necessary to design a haptic feedback pattern according to the situation. In order to solve this problem, we focused on the "impression and situation" that the pattern of haptic feedback gives to the user in various situations.

2. About the experiment

In this research, we investigate what kind of impression the user receives for haptic feedback. Hypothesis: A specific image can be given by tactile sense.

In order to verify the above hypothesis, we set up surveys of ① and ②.

①: Collection and convergence of various haptic feedback patterns
②: Impression evaluation of haptic feedback pattern collected

2.1 Collection of haptic feedback patterns

Various patterns and their convergence are necessary to collect patterns according to the situation. So we asked 5 collaborators (students) to create.

We used Arduino IDE (Arduino) and library Adafruit DRV 2605 Library for pattern creation. Arduino is a microcomputer board and is used for prototyping etc. The equipment used is 1100 rpm at 5 V with the microcomputer board FLORA (made by Adafruit) and the DRV 2605 L vibration feedback module (the same manufacturer) and the coin type vibration motor Vibrating Mini Motor Disc (the same manufacturer). There are 116 kinds of commands available in the pattern, and up to seven commands can be combined in the pattern. Also, the patterns created by collaborators are four: joy, anger, fear, and relief. By this alone, the degree of difficulty to create is increased, so we chose expressible expressions to connect with 4 patterns using a book called emotion expression dictionary.

The following is a description of the pattern created by collaborator A.

Table 2.1.1 Haptic feedback pattern created by collaborator A

2.2 Impression evaluation experiment of haptic feedback pattern

In order to investigate the impression of the created pattern, various opinions were collected. We conducted an investigation using impression words for impression evaluation. Regarding impression words, we refer to past studies [1], [3]. The outline of the experiment is shown below.

2.3 Outline of experiment

Implementation Period: December 12 - 27, 2016
Experiment subjects: 21 elderly (11 males, 10 females), 12 healthy young people (8 men, 4 women)
Experimental place: Kyoto Institute of Technology 15th Building, Building 1
Experimental tool: Equipment used in pattern collection, experiment model ([138×66×10] mm)
Survey item: Investigate the impression of user-defined feedback pattern

Implementation method: Impression evaluation experiment was conducted by giving information of 5 steps of Semantic Differential (SD method) and situation of 1-5 using 8 collected patterns and impression word pair.

3. Experiment results

In this experiment, patterns created for subjects were experienced randomly in each of the three situations (request, reminder, report). Subjects are divided between young and elderly groups. And among them are young healthy people and elderly groups in request situation. This also applies to reminder and report. Among them, there was a significant difference between the impression received by the subject and the elements constituting the vibration such as the magnitude and length of the vibration.

Fig. 3.1.1 Vibration No. 8 Evaluation of anger (Elderly)

The way of viewing this graph is as follows. For example, when the score of C (dark-bright) score is high, the subjects have a bright impression.
Both the elderly and the young people highly rated No. 8 and rated No. 5 low. The difference between the two vibrations is that the magnitude and vibration interval are different.

4. Summary of Experiment

From the research of this research, I found the necessary elements for the haptic feedback pattern suitable for the situation. First, although a significant difference appeared between the request and the report, it did not appear in the reminder. Because this was not so familiar with prompting, I think that it was because Nuance 's way of catching was limited compared to the other two. As for the request, it became clear that the elderly person can give the impression of clear impression, brightness, comfort, strength, by enlarging the vibration. During the experiment, we considered that favorable evaluation gathered in a large pattern that was easy to judge because it was difficult to distinguish weak patterns. Pattern No. 8 was created by imaging anger, but many elderly people had a positive impression (Table 3.1.2). There seemed to be few people feeling discomfort to large vibrations. In the case of young people the maximum and heaviness - a light correlation, a weak - strong positive correlation was seen. As for young people, there were many subjects who received impressions similar to those of preparers for pattern No. 8 (Table 3.1.3).

5. Discussion

As for the reason why the way of capturing the impression of young people and senior citizens differs in terms of requests and reports, it is thought that many elderly people are not so familiar with equipment equipped with haptic feedback such as smart phones and game machines compared to young people. As a result, older people tended to receive large vibrations positively. Or because the collected patterns were created for young people, it is thought that the opinion of the elderly is not reflected, which is considered as a factor.

6. Conclusion

The following conclusions are summarized from these analyzes.

I . The impression that the magnitude of haptic feedback gives to users is different.

II . Depending on the situation the user's impression on haptic feedback is different.

Although it was partial, I could prove the hypothesis "can give a specific image by tactile sense".

7. Future Challenges

Although we gathered diverse patterns, there are biases in the creators, and there are problems such as difficulty of cooperators for pattern creation being not visual. Also, since feedback constituent elements are also uniquely defined, it is necessary to examine the experiment and consider the correct setting.

Abstract

This paper presents the main process of a graduate course entitled ‘Generative Design Research for Sustainability’ offered in the Department of Industrial Design at Middle East Technical University in the spring semester of 2015/2016 through exemplary design research cases conducted by the graduate students at the doctoral level. These cases focus on the adaptation of the generative tool and the method, namely Experience Chart (EC) Guide tool (Kulaksız, 2016) and Experience Reflection Modelling (ERM) method (Turhan, 2013), in line with the graduate students’ particular research topics. First, the paper provides the course objectives, outcomes and process, then, it explains the EC Guide tool and the ERM method to be adapted and implemented within the context of the course. Then, these generative tool and method, and their adaptations are demonstrated through the exemplary cases (i.e. efficient use of working environment in design studios, lighting practices in kitchen environment, and interactive prototyping practice) selected from the submitted assignments considering their quality, originality and comprehensiveness. The main emphasis of this paper is on the adaptation and implementation of the EC Guide tool and the ERM method through providing the experiences, insights and suggestions of the graduate students who are also the co-authors of the paper. Based on that review, major conclusions and findings are presented through comparing and contrasting these cases for the future development of the course.

Keywords: Generative Research Methods and Tools, Sustainable Design Considerations, Design Research, Qualitative Research, Industrial Design

Literature Review

‘Generative Design Research for Sustainability’ course provides the graduate students with a
basis for a better understanding of generative research approaches in line with design considerations for sustainability such as enabling post-use services including product maintenance, repair, upgrading via product part replacement and/or refurbishment, and understanding local usage patterns and encouraging effective use of resources (e.g. energy, water, etc.) (Turhan & Dogan, 2014). It includes the exploration of current issues in participatory and generative research approaches (Sanders & Stappers, 2014) for integrating sustainable design considerations; the examination of various generative tools and methods for having a better understanding of people’s needs, preferences and desires by involving them in design research, and facilitating their active involvement (Martin & Hanington, 2012; Hanington, 2007, 2003; Sanders, 2008; Sanders, Brandt, & Binder, 2010; Sanders & Stappers, 2013); the development and implementation of an activity and/or product oriented design research project incorporating sustainability considerations into these methods and tools; the discussion and presentation of findings and conclusions from the generative design research projects. Throughout this course, the students:

- Understand the current issues in participatory and generative research approaches;
- Examine various generative tools and methods, including the Experience Chart (EC) Guide tool and the Experience Reflection Modelling (ERM) method for design researchers;
- Conduct user observations via the EC Guide with participants on a selected activity and/or product;
- Prepare a research brief integrating sustainable design considerations for the selected activity and/or product;
- Develop and implement EC Guide as a generative research tool;
- Discuss and present findings and conclusions from the EC Guide adaption and implementation;
- Develop, adapt and implement ERM as a generative research method;
- Discuss and present findings and conclusions from the ERM sessions;
- Develop research directions for idea generation phase; and
- Evaluate and present the generative design research process.

Research Methods

This paper is based on the perspectives of various people involved in the course (i.e. graduate students, and two course tutors), and communicates its conclusions and insights through their involvement as the principal and co-authors. The course is offered by two of the co-authors, Doğan and Turhan, who developed the ERM method within the context of Turhan’s doctoral thesis (Turhan 2013) and undergraduate design education projects. Similarly, the EC Guide tool was developed by two of the authors, Doğan and Kulaksız, as part of Kulaksız’s master’s thesis (Kulaksız, 2016). Other authors are the doctoral students and research assistants in the Department of Industrial Design whose final course submissions are presented as exemplary cases in this paper.

Throughout the course, the graduate students adapted and implemented the generative design research tool (i.e. EC Guide) and the method (i.e. ERM) considering their design research topics and related products or/and activities. They integrated these tool and method into their
design research to better understand sustainable design considerations derived from the perspective of potential users, and to develop research directions for idea generation phase. They also recorded their experiences and insights, and shared these with the course participants via presentations and class discussions. These submissions included observational, evaluative and reflective feedback from the graduate students and they are presented in this paper.

Experience Chart Guide for User Observations

The EC Guide is a user observation tool that is particularly developed and assessed within the design education context (Figure 1 & 2). It aims to guide design students while capturing and documenting user observations as part of exploratory research to inspire and inform their early design decisions. It helps them remember and pay attention to important considerations before, during and after the user observations.

The EC Guide (Figure 1 & 2) starts with the empathy as a pre-observation stage conducted by the students individually. This is followed by four main stages that are participant & environment, observations, thinking aloud, and memories & dreams with the involvement of the participant.

Figure 1. Front page of the EC Guide.
Empathy: The students explore the activity of inquiry to get familiar with it before the user observations, and document their individual experiences. This familiarization enriches their knowledge about the activity, its phases and context, and the related product(s) of focus that would make them more attentive while observing the participants. The students can easily recall their own experiences during the user observation by referring to this part and ask participant her/his opinion about issues that they would remark during their own engagement with the activity.

Participant & Environment: The students document their general impressions about the participants and the activity environment. Although they are flexible about the type of information to seek and express in this stage, they are advised to pay attention to the interaction between people, objects and activities existing in the field of observation. Insights gathered in this part help the students evaluate and analyse the observation findings within its context.

Observations: The students observe their participants while they carry out the activity of inquiry, and document their insights on the timeline provided. They pay attention to and highlight activity phases, perceived experiences of the participants corresponding to these phases, and feedbacks that the participants receive from the activity environment.
Thinking Aloud: The students together with the participants go over the notes documented during the observation to better understand their viewpoint. The students ask for clarifications and explanations to understand the underlying reasons of the participants’ activity related behaviours. The students also ask them to demonstrate the activity phases via enacting. By doing so, they are able to take photographs for each activity phase and important details without the concern of disturbing the natural course of the observation.

Memories & Dreams: The students interview the participants about their past experiences (i.e. memories referring to complaints, accidents, appreciated qualities and alternative uses) and future expectations (i.e. dreams referring to suggestions and further ideas) regarding the activity of inquiry. By doing so, they gain more detailed insights from the participants that might be difficult to receive during the previous stages. As the participants just experience the activity of inquiry, it is easier for them to recall their earlier experiences and generate their future expectation by reflecting on the whole process (Sanders & Stappers, 2012).

The students are also provided with a digitally editable EC Poster template as a presentation medium of user observation findings (Figure 3). It has similar characteristics with the EC Guide, and facilitates the communication of insights through a semi-defined layout. Within the content of the course, the students were asked to conduct two user observations via the EC Guide considering their specific research topic, and present their insights in the EC Poster format.

Figure 3. The layout of the EC Poster template.
Experience Chart Guide as a Generative Tool

The graduate students evaluated the EC Guide tool and their experiences with it during user observations, as they were required to develop it as a generative tool for gaining more insights into user needs and preferences for their specific research topic. In order to proceed this process effectively, they needed to think about it step by step from the recruitment of participants, the distribution of the adapted version the EC guide as a generative tool, collecting the filled-out generative tools, and to the analysis and presentation of the findings and insights from this phase.

First, they focused on a specific activity considering the findings from user observations. They were advised to go through the limitations and challenges that they faced during user observations, and highlighted them on the EC guide for further iterations. Based on our class discussions in class, they developed insights, and incorporated these into their generative EC Guide that they would develop.

The EC Guide includes a timeline that has generative research features in terms of its ability to get people involved in the process. For instance, potential participants can easily take notes on this timeline to reflect on and share their experiences. The visualization area in the original guide aims to get feedback from the potential participants. These features can be enriched with other alternative parts for the EC guide in order to prime the participants in the process, thus to provide further insights through engaging them in the process more effectively (i.e. activity phases, positive negative experiences and feedback). The EC Guide as generative research tool may include different interconnected phases some of which can be experienced individually by the participants, whereas some can be facilitated by the involvement of the researcher.

Considering the development of generative tool and the changes that the graduate students embraced, they adapted the layout of the EC Guide and the EC poster template. Besides, they enriched their generative toolkit by including necessary instructions. They also provided a summary of their experiences, insights and suggestions while developing and conducting their generative EC toolkit.

Experience Reflection Modelling

ERM, as a design research method (Figure 4) enables people’s involvement in the early stages of the design process to help design researchers better understand people’s needs, expectations and preferences regarding an activity and/or product through creating a medium for knowledge transfer (Doğan, Turhan, & Bakırlioğlu, 2016; Turhan & Doğan 2017, 2014).

Within the context of the course, the students developed a draft ERM toolkit and interview schedule, and evaluated these for further development via focusing on the selected activity of their research area. They used their toolkits and interview schedules for rehearsals to be held during the class. The rehearsals are essential to get familiar with the ERM sessions, understand the difficulties related to the conduct of the sessions, and enable students to assess and further develop their ERM toolkits and interview schedules.
Figure 4. The phases and components of ERM.

Developing the interview schedule: Interview schedule includes brief information for participants, questions related to a lifespan of a product, and questions about additional features and improvements regarding the product. The questions should be developed based on the design considerations in the research brief. The format of the interview schedule should enable the students to easily follow.

Developing the ERM toolkit and the drawing file: An ERM toolkit comprises of 2D and 3D parts which have the potential to represent particular components of a product category. Diverse and various parts can be added as much as possible. However, the parts should represent abstract forms, so that the preferences of the participant won’t be led by the aesthetic features of the parts. In addition to the pre-defined parts, different materials such as play dough, coloured papers and pens, fabric, wire, etc. can be added to meet the request of the participants. Putty-like adhesives such as Tack-it, Blu-Tack or tapes are used to bring together the parts during the 3D modelling phase. The main focus in the toolkit development is to provide diversity to enable the participants to personalize the 3D model based on their preferences.

Conducting the ERM session: During the sessions, the student asks questions by using the interview schedule, and the participant responds as she/he brings together the components of the toolkit. Asking the reasons of the participant’s responses should not be missed, since these would help the student make better interpretations from the ERM analysis phase. The sequence of the
questions may change in line with the responses of the participant. The student should encourage the participant to use the toolkit while responding the questions. The student should not direct the participant while helping the 3D modelling phase. When the participant adds parts to the model and makes changes on the model, the process should be documented for the analysis phase of ERM.

**The Adaptation of the EC Guide Tool and the ERM Method**

**Case 1: Efficient use of Working Environment in Design Studios**

In this case, the researcher explored the efficient use of working environment in design studios in terms of model making process involving materials and tools. Their storage, transportation and life-cycle in the design studio environment were observed and analysed related to sustainable considerations such as effective use of materials and environment. Third-year industrial design students, their design studio environment and design project processes were selected to be explored.

**The EC Guide as an Observation Tool:** The brief of the EC Guide indicates that this tool can be used for a specific product/activity for a short period of time. However, the research in this case contains an environment, a series of activities within a system which are carried out in a long period of time (over a few days), investigating students’ attitudes during model making process in the design studio environment.

Due to the time limitation, *observation* stage was completed during the third-year industrial design studio course hours; although, to observe the whole model making process continued at least a week within and/or outside the studio hours. The EC Guide directs researchers to observe activities step by step; however, this case does not consist of these successive steps. After completing the *observation* stage, the researcher and participants came together, and passed over the notes in the *thinking aloud* stage, which provided the researcher with the opportunity to evaluate findings together with the participants. Due to the intermittent nature of activities, to switch between these two stages became harder. In the last stage of the tool; while *memories* part was like a repetition of the *thinking aloud* stage that the participants talked about their old experiences, *dreams* gave them the opportunity to analyse their thoughts and create new ideas. The EC guide was very effective in terms of organizing the observation process. The division of the process into different stages helped the researcher examine the research area from different views.
The EC Guide as a Generative Tool: While developing a generative tool, the EC Guide was adapted and reformed in order to gather insights from the participants. The layout and the content of it were changed, and it would comprise of seven stages including project definition, project process, model making process, definition of problems and suggestions for problems divided into three: environment, actor and product/system (Figure 6). First and second stages were formed to make participants familiar with the process. Next two stages were asked to participants to explain their model making process and the problems being encountered in this process, and remaining stages aimed to incorporate suggestions into these problems, and their visualisation via quick sketches and diagrams.
Due to the lack of explanations on the adapted EC guide, the participants could not complete it as planned. Therefore, the adapted EC Guides were collected and revised, and the participants refilled them. It is very significant and critical to make each stage clearer and more descriptive. After the researcher went through the charts, the information gathered was reviewed together with the participants, and the missing parts were clarified. This stage supported the findings, and helped the participants rethink their notes. To arrange and categorize the stages of the activities, and match those with the photographs effectively the EC Poster (Figure 7) was prepared.

This experience is more participatory-oriented, so that every detail needs to be considered carefully. The researchers have no chance to interfere with the process. Making the participants more willing to and comfortable with filling out this toolkit can lead to collecting deeper information. Before the analysing stage, meeting with the participants is important to resolve incoherent parts, and to make every detail clearer.

The ERM Method: For the ERM method, the research topic mainly focused on organising the studio environment, model making tools and materials. Prior to the ERM sessions, interview schedule and toolkit were prepared, and a rehearsal session was conducted during the course hours. This process informed the researcher about how the process would work, and helped her/him identify problems and reorganize the process accordingly.
One of the most difficult stages of the ERM method was preparing the toolkit for a design solution which would not exist until now, so the toolkit was developed based on potential design solutions. Therefore, generally various sizes of 2D forms which can be used in developing 3D models were preferred (Figure 8).

![Figure 8. The ERM toolkit (left) for Case 1, an example from an outcome of the session (right).](image)

The participants were familiar with the topic, since they attended the first observation stage. The researcher asked the participants to decide on their suggestions for a proper scale, and marked the area on the wall with the paper tape, which became very helpful for the rest of the process. This marked area was utilized for other solutions. The participants tried to find solutions in terms of their past model-making experiences, and the ERM toolkit helped them recall their problems, and express their needs. In addition, the plan of the studio environment was given to the participants in order to foster their imagination, and help them provide their insights and suggestions more effectively.

During the analysis stage, based on the sustainability considerations, including effective use of materials, tools and environment, the insights and themes were arranged and their connections were formed. For the poster presentation, many elements such as photographs, drawings, quotations and graphical representation were used (Figure 9).
Case 2: Lighting Practices in Kitchen Environment

The researcher, in this case, explored the lighting practices in kitchen environment to gain insights into the users’ diverse needs, experiences, expectations and concerns related to electricity consumption. Participants’ use patterns and insights were acquired and analysed in line with the related sustainability considerations including resource effectiveness, clarity of feedback and adaptability to user needs, preferences and use behaviours.

The EC Guide as an Observation tool: The researcher used the EC Guide as an observation tool in two diverse households while participants performing activities such as preparing food, serving tea and cleaning dishes. The empathy stage of the EC Guide enabled the researcher to recognise the potential interactions and use patterns that need to be further explored through the actual observations, and also to develop probe questions for more detailed participant responses. During observation stage, as the main activity continued for a long period of time, the researcher preferred to take photographs without interrupting the activity and explored these further in the following stage. Thinking aloud stage complemented the observations, and revealed detailed...
information about the participants’ concerns and insights that were difficult to receive solely through observations. In memories and dreams stage, the data received from the participants was quite detailed, yet often irrelevant to the main focus of the study. In the visualisation area located in this stage, even the researcher tried to encourage the participants to draw, both participants hesitated to visualize as they felt uncomfortable with the quality of their sketches. The design of the EC guide, including interrelated phases, enabled an effective analysis process. The documented data was easily transferred into the EC Poster (Figure 10).

As adapting the EC Guide, documenting the participants’ activity patterns and responses simultaneously was often found difficult which might have been supported with voice recording. The incorporation of the EC guide requires some effort from the researcher while facilitating the sessions, yet the received data is quite detailed compared to conventional user observation.

The EC Guide as a Generative tool: As adapting the EC Guide as a generative tool, the researcher reconsidered the main focus of the research and limitations of the previous phase. In that sense, the guide was revised through including new phases (i.e. frequency and duration of use, electricity consumption, etc.) and omitting (i.e. empathy phase) or combining others (e.g. problem areas) to be able to capture the participants’ experiences and insights that would be essential for the particular research. She also included a complementary semi-structured interview session to probe into the participants’ statements documented on the tool. The adopted
guide was distributed to two participants to be filled out and returned prior to the interview sessions to prepare an interview guideline.

The adopted generative tool has six stages including **use environment, frequency and duration of use, use experience, resource consumption, problem areas** and **design suggestions** (Figure 11). In the **use environment** stage, the participants were asked to take the photographs of the kitchen environment, and note down the number, location and features of the existing light sources.

![Figure 11. Adapted version of the EC Guide as a generative tool for Case 2.](image)

In the second stage, the participants were asked to track their lighting patterns throughout the day and record the frequency and duration of use on separate timelines provided for each light source. In the **use experience** stage, the lighting use patterns in the kitchen were documented as performing a certain activity (e.g. preparing food). In the **electricity consumption** stage, the participants were asked to visualise the intensive or unnecessary resource use in the related use patterns defined on the previous stage. The aim of this stage was to explore participants’ understandings and their perception of resource use rather than evaluating their knowledge. The **problem areas** stage questioned the lighting patterns leading to intensive/unnecessary resource use while the final stage, **design suggestions**, asked for the participants’ design suggestions to reduce electricity use resulting from the lighting behaviours.

The EC Poster format was revised to be able to present the findings and insights effectively (Figure 12). The adapted toolkit and interview sessions required some effort from the researcher and the participant, yet, the received data was quite comprehensive.
The ERM Method: Within the context of the research, ERM was adopted through a scaled model of a kitchen environment and one-to-one model of the light switches. Prior to the sessions, an interview schedule was prepared encompassing use experiences, concerns related to the electricity consumption and such to guide the sessions effectively. The 3D modelling toolkit was prepared including materials such as cardboard parts, coloured pens, play dough, tape, tack-it, acetate, and rope (Figure 13). Through a rehearsal session, the toolkit as well as the guideline was revised (e.g. the ceiling with a grid-like structure to ease hanging lighting units, etc.).
The sessions were carried out with two participants with the help of another researcher for audio visual recordings. As engaging with the toolkit, the participants used the parts quite effectively and even unexpectedly (Figure 13). For instance, the parts developed for the light sources (i.e. tubular fluorescence lights) were used to support the main structure of the kitchen. The waffle structure walls enabled the participants to create overall environment easily while the grid structure of the ceiling allowed them to manipulate the environment quite effectively.

The video recordings were verbatim transcribed and interpreted to develop sustainability considerations and themes. Later, the findings from the ERM sessions were transferred to a poster through demonstrating the relations between the considerations, themes, insights and images from the ERM sessions with specific time slots (Figure 14).

Case 3: Interactive Prototyping Practice

The researcher in this case aimed to investigate skills, knowledge acquisition and storage habits of industrial design students practicing open-source interactive prototyping tools. The structure and the aim of the research were shaped in accordance with the sustainability considerations to gain insights about the causes of material waste during the prototyping activity.
The EC Guide as an Observation tool: The EC Guide was utilized in the study with two participants who were asked to make a simple interactive prototype of a product of their own choice. At the empathy stage, the past experiences with the prototyping activity were documented by the researcher to get familiar with the phases in order to develop the questions to be asked in the next stages of the study. At the Participant & environment stage, the essential information about the participant and the environment was documented. However, it was challenging for the researcher to execute observing the environment, photograph-taking and question-asking procedures all at once. During the observation and think aloud stages, most of the observation process went flawlessly in terms of data collection, which provided considerable amount of data. Memories and dreams stage was useful for visualising the participants’ experiences, expectations, and to summarize all the cons and pros. The elements questioned in dreams section of this stage (i.e. suggestions and further ideas) could be combined into a single area, since it creates some confusion.

The use of the EC Guide for user observations allows the researchers to gain reasonable amount of key data which was extracted from the participants (Figure 15).

The EC Guide as a Generative tool: The EC Guide was flexible to adapt for the research topic of inquiry. It also allowed the researcher to improve it considering the previous phase to fit the needs of prototyping activity. The adapted tool (Figure 16) was utilized in the study with four participants, all of which were third-year industrial design students. All of the stages in the

![Figure 15. The EC Poster for one of the user observations.](image-url)
adapted tool included clear explanations of how they should be completed. *Activity timeline* stage included three different timelines grouped and presented together, which were *physical*, *phigital* and *digital*, as they represented different aspects of prototyping activity. *Phigital* is a new word which is a combination physical and digital, since particular prototyping activities can be both. Positive, neutral and negative signs were advised to be used as bullet points to understand simply how they feel about a certain phase. Furthermore, *follow up talk* stage was added to replace *memories & dreams* stage, to elaborate more on the study conducted with the help of the researcher, after the earlier phases were completed by the participants individually. The participants were encouraged to take photograph, which led the researcher to collect more data from that particular prototyping activity.

![Interactive Prototyping Practice Guide](image)

Figure 16. Adapted version of the EC Guide as a generative tool for Case 3.

In this stage, the participants had the opportunity to visualize their experiences and ideas with simple sketches, most of the points were made clearer with verbal explanation.

**The ERM Method:** Before starting the ERM sessions, the models of the essential standard components, storage units, tools and a laptop computer were produced for the participants so that they could transform them whichever they preferred (Figure 17).
A voice recorder, a camera and a video recorder were used for the sessions for audio-visual recordings. Pens, tape bands, adhesives, cutting tools and many other transformation tools were utilized during the sessions for the participants to modify their models by the toolkit, to show where the problems are, and the key points of how the enhancements can be made.

Two participants were volunteered for the sessions to be carried out. One of them was a doctoral student, while the other one was an undergraduate student, both were experienced about the interactive prototyping.

The participants were reluctant to make any changes on their ERM models, since the components/parts of the ERM toolkit were designed in a very detailed way. Interestingly, the participants were willing to complete an interactive prototype for the activity, which was not the main aim (Figure 18).

One of the most useful toolkit element in the sessions was the waffle structure which helped the participants create separators, boxes, and even prototypes in a much faster fashion than a standard planar element.

Figure 18. An example from an outcome of the session: a prototype and an attachable storage unit created with the toolkit.
In the analysis part, the key insights and solutions provided by the participants were rephrased. Main research themes were generated according to the data extracted from the sessions. The presentation board (i.e. ERM Analysis Poster) was developed around three different strands of the main research considerations which were storage practices, skills and knowledge acquisition and waste/leftover materials and/or parts (Figure 19). The insights and solutions gathered from the analysis of the sessions were placed on the board and connected together when related to another insight, solution or consideration.

![Figure 19. ERM Poster presenting the findings from the sessions.](image)

**Conclusions and Insights**

The integration of the generative tool and method into the ‘Generative Design Research for Sustainability’ course would enable the educators to understand the potentials of the adaptation of EC Guide and ERM, and further develop the course accordingly. This experience would also encourage the graduate students to adapt diverse tools and techniques, and to develop their own methodology in their future design research projects.

Using templates for the adaptation of tool and method (i.e. EC Guide and ERM) appears to be helpful and engaging for the students. The Experience Chart part in the EC Guide mainly follows
a linear process which is effective for more specific activities (e.g. brewing tea, coffee, baking, grilling, etc.). The adaptation of EC Guide appears to be particularly difficult for the research topics to be explored in the long run – such as activities and tasks involved in design studios for the duration of a design project.

The adaptation of EC Guide led to the alternative and new stages to be included in this tool such as *model making* processes and *design solution* areas for the first case, *resource consumption* for the second, and *physical/digital prototyping* stages for the third one. Encouraging the participants to take photographs for documenting their experiences was somewhat challenging for the researchers, and alternative means of doing this could be searched – such as uploading images to blogs or online platforms while considering the confidentiality issues (e.g. restricted or private access of collected data). Areas for visualisation on the adapted EC Guides pose also challenges for the participants with no or limited skills for sketching and/or drawing. In that case, the role of researcher would be more prominent in facilitating and helping with this process.

The participants in some cases required further clarification for some of the components of the adapted EC Guides, which led to further revisions in the research phase. Within the time limitation of the course, the researchers were only able to understand and experience initial constraints of the EC Guide tool and the ERM method, which could be further explored with additional researches or pilot studies.

For the ERM adaptation, the researchers developed very detailed and thoroughly designed toolkits involving many parts which could be tailored to the participants’ needs and preferences for personalization. The development of the toolkit can be considered as a lengthy process, and for educational learning goals and outcomes, this process could be planned as a teamwork, or some of the components can be co-developed and adapted through a more collaborative approach. Some toolkit parts, for instance the waffle structure, was mutually incorporated into the ERM toolkit by diverse researchers, which would show that a pool or an online platform for sharing ERM toolkit could be created for studies focusing on diverse areas. This might also decrease the number of toolkit parts remained unused. The researchers also needed help while conducting the ERM sessions in terms of audio-visual recordings. As different areas in the room were used throughout the ERM session, the angle of the cameras required to be changed accordingly. For that reason, these sessions should be planned and organized comprehensively in advance.

The adaptation and incorporation of these engaging EC Guide tool and ERM method into the course schedule led to a very intensive but productive process for the graduate students, which could potentially help them plan and facilitate their future researches through adapting a more participatory and generative approach.

**Author Biography**

**Mert Kulaksız**

He is a graduate student at the doctoral level in the Department of Industrial Design, Middle East Technical University (METU) in Ankara, Turkey and works a research assistant at the same institution. His research interests includes user observations as a part of the exploratory design research, generative design research methods, and evidence based design in design education. He holds M.Sc. and B.ID. degrees in industrial design from the Department of Industrial Design, METU. His master’s thesis explored the potentials of a user observation tool for collecting user data to inspire and inform the early stages of the design process. He also works a design researcher at METU/BILTIR- UTEST Product Usability Unit since 2016.
İltr Güngör Boncukçu
In 2012 she graduated from the department of Industrial Design at Middle East Technical University (Ankara, Turkey) and in 2015 she received her master’s degree. Research for masters focused on the 3D virtual worlds as new learning environments for industrial design studios. The aim of the master’s thesis was firstly to explore 3D virtual worlds in terms of their current state in the world and secondly, to examine educational applications and to discuss their potentials, possible advantages and disadvantages for ID education. She now works as a research assistant and is working towards her PhD at METU, Turkey. Her research interest includes design education with focus on new learning environments, teamwork, participatory design, the use of online tools in design education, sustainability, and system/service design.

Dilruba Oğur
She is graduate student at the doctoral level in the Department of Industrial Design, Middle East Technical University (METU) in Ankara where she also works as a research assistant. Her doctoral research focuses on exploring individuals’ everyday practices responsible for intensive household electricity and water consumption to influence them towards sustainable directions through developing design directions with a generative approach. She holds a M.Sc. (2014) and B.ID. (2011) degrees in industrial design from the Department of Industrial Design, METU. She is also a researcher at Sustain Design Research Lab (SustainDRL) at METU since 2014. Her research interests include product design for sustainability, design for behavior change and generative research methods.

İsmail Yavuz Paksoy
He graduated from the department of Industrial Design at Izmir University of Economics (Izmir, 2012) and he received his master’s degree from Middle East Technical University (Ankara, 2016). The aim of the master’s thesis was to explore attitudes towards 3D surface textures for functional and hedonic product improvement. He now works as a research assistant in Middle East Technical University, where he is also a graduate PhD student. His research interest includes design for interaction, additive manufacturing, interactive prototyping, IoT, and industry 4.0. He is also an entrepreneur, since he is the cofounder of a company where medical utility devices are designed for diabetic patients.

Senem Turhan
She is both a design researcher and an educator. Her study areas are human-centered research (generative research, participatory approaches), design thinking and futures thinking. She pursued her post-doctoral studies at UNSW, Sydney. She previously worked as a post-doc researcher at SustainDRL and research assistant at Middle East Technical University. She got her M.Sc. and Ph.D. degrees at the same university. Her master thesis is about the state of sustainable design education in the undergraduate industrial design programs in Turkey. Her doctoral study focuses on generative research for the idea generation phase of the product design and development process.
Çağla Doğan
As a design educator and researcher, she has knowledge and experience at undergraduate and graduate levels. She has several years of teaching experience, including industrial design studios and related theory courses, as well as graduate thesis supervision. She has a well-established research focus on design research and education for sustainability and numerous publications in this field. She also has much experience in interdisciplinary teams and learning. She holds a Ph.D. in product design for sustainability from the Faculty of Environmental Design, University of Calgary, and M.Sc. and B.ID. degrees in industrial design from the Department of Industrial Design, METU in Ankara where she has been founder and projects coordinator of the Sustain Design Research Lab. Her design-based research focuses on product design, design research and design education for sustainability, particularly integrated scales of design and production i.e. relationships among batch production, mass production, craft, do-it-yourself and open design; localization and personalization – product value, longevity and meaning; generative research for sustainability; and grounded theory and research through design.
Social Value Creation through Multidisciplinary Design Education

Steven Kyffin, Pro Vice Chancellor, Northumbria University, Newcastle Upon Tyne, steven.kyffin@northumbria.ac.uk  
Mersha Aftab, Senior Lecturer in Innovation, Northumbria University, Newcastle upon Tyne, m.aftab@northumbria.ac.uk  
Nicholas Spencer, Senior Lecturer, Northumbria University, Newcastle Upon Tyne, nick.spencer@northumbria.ac.uk

Abstract

The paper proposes that design with a multidisciplinary student cohort as active partners can play the role of bringing the four different stakeholder groupings, namely, government, industry, society and academia together within the creative consortia, and create innovation for the greater good of the society.

By studying a selection of social innovation projects undertaken by multidisciplinary student teams as connector-integrators, which engaged with companies, government bodies and community groups, we have examined a combination of ‘four’ different activities across different economic and cultural (human experience) contexts to assess their different degrees of appropriateness in creating future value.

We apply these methods to establish ‘creative consortia’, which has enabled us to reframe the context of the problem space. We believe that the creative consortia has the potential to create more relevance in the solution space, greater engagement in realising the proposition into the future, and a higher opportunity for integration of such future principles into emerging government policy, and national innovation agendas.

Key words - Creative Consortia, Multi-stakeholder Collaboration, Learning and Teaching, Social Innovation, Student led Innovation.

This investigation is a result of post rationalisation of social innovation projects undertaken by the academic group called Multidisciplinary Innovation comprising of students, academics and researchers. The purpose of this reflective investigation was to consolidate a methodological framework involves the students in a connector-integrator role in order to create a successful multistakeholder framework within the premise of learning and teaching environment. Evidence collected from three distinct multidisciplinary student driven social innovation projects highlights the existence of a framework of stakeholders called the ‘creative consortia’.

Multidisciplinary teams co-create and propose innovative and meaningful value for people, and ensure maximum impact, however, the decisions on ‘who’ the stakeholders are, ‘how’ can this collaboration work, and ‘what’ value each stakeholder gains are all questions that surround such collaborations. The challenge for design is to find ways to engage all these stakeholders to propose futures, which offer meaning, value and a sense of transformation for society as a whole. This research sought to answer the following research question: how does a university through a student-led innovation programme ensure that the creative
consortia is maintained, that value is created for all involved stakeholders, and that citizens are empowered?

**Background**

The student projects, part of the MA/MSc Multidisciplinary Innovation programme (MDI), were used as an experiment to consider the principles and practices successful in achieving social innovation to take place on behalf of the client partner. A small number of the students (3-5) were put in multidisciplinary teams (comprising of design, engineering, business, psychology), so that no single disciplinary perspective was dominant, and provide a more comprehensive view on the variety of projects reviewed.

The first project with The Low Simonside was undertaken within a three-week period, and it concluded in ‘stimulating’ the client’s thinking. The work stimulated the client to take action based upon an enhanced understanding of the community, based on insights about the differing needs of the community that the Low Simonside Community Centre serves. The project also energised the community by enhancing their involvement in future change.

The second project is The Town of Colour project, conducted in three phases over two years; the students carried out the first two phases, and the third phase was carried out as contract research. This project realised a much greater impact on the community and has triggered a series of funded community enhancement projects in the project’s town.

The third project with The Percy Hedley Foundation project is on-going. The first phase for this project, conducted by the student community, over a three-month period in 2014, resulted in ‘organisation stimulation’, where students acted as a catalyst for the client. This organisational stimulation led to the Percy Hedley Board of Trustees agreeing to and securing funding for phase two. The second phase being more research-focused aimed at developing a model of responsible enterprise for and operating across the Percy Hedley Foundation. The research provided a platform and route to establishing new enterprise behaviours and activities through appropriate governance, leadership and support.

**Literature Review**

**Design Led-Social Innovation**

Interest in social innovation comes from a variety of fields, including social entrepreneurship, technology, public policy, urban and community development and social movements, with each contributing their own methods and insights (Mulgan, G., 2007). Design (thinking), however, is perceived to be particularly well-suited to tackle many challenges that social innovation poses as it offers a creative approach that combines prototyping potential solutions, actively involving stakeholders and addressing users' needs, with the ability to go beyond established assumptions (Brown & Wyatt, 2010; Murray R. et al. 2010).

Jégou & Manzini (2008) characterise the use of creativity to change and improve existing thought patterns and behaviours by recombining products, services, and knowledge as design-led processes. Manzini, E. (2014) distinguishes two modes of operation in these
processes: when designing with communities, professional designers are participating as peers with the other stakeholders in a project. Here, designers need to support and facilitate the collaboration among the different stakeholders and in the construction of shared visions and scenarios. When designing for communities, however, designers provide solutions for collaborative services (co-created multiple stakeholder projects) in order to make them more accessible and effective by developing digital platforms, scenarios and organising events such as exhibitions and festivals.

Although design led social innovation is known under various different names, such as design and social innovation and design for social innovation, and its definitions are in constant flux due to the on-going discourse, Westley, F. et al. (2012), Chick, A. & Micklethwaite, P. (2011) and Chick, A. (2012) find that credible models share the following common characteristics:

1. Broad-based research
2. Co-creating the solution
3. Conducive physical space(s) that aid creativity and reassures participants
4. Clear process design and facilitation
5. Engaging hands-on design devices (sketching, mock-ups, prototyping and design games)
6. Multidisciplinary support team
7. Tools that aid reflection on the nature of the work and its possible and actual impacts
8. Continual professional development of designers and other team members

The fact that design and designers can play an important role as facilitator-connector in social innovation has been recognised by several authors. Mulgan, G. et al. (2007) state that the people and institutions which connect different people (designers, among others), ideas, money and power play a crucial role in social innovation, forming new social relationships between individuals and groups which were previously separate from one another. Cipolla, C. & Moura, H. (2012) regard design as a connector as one of the design approaches to social innovation, which entails the mapping of the physical, human or strategic resources and understanding their interactions, envisioning relationships that are more sustainable and prototyping them as part of an integrated system. Manzini's (2015) collaborative organisations, made both possible and likely by design for social innovation, are social groups that have emerged in a highly connected environment. In addition, their members collaborate in order to achieve specific results, creating social, economic and environmental benefits.

However, Chick, A. (2012) asserts that designers no longer limit themselves to researching and designing together with stakeholders within a project. Instead, designers are moving beyond project boundaries by enabling future stakeholders to continue the design process. Defined as 'infrastructuring' by Hillgren, P-A, Seravelli, A. & Emilson, A. (2011), it focuses on long-term commitment from the stakeholders, keeps the design structure open-ended and does not need to feature formal elements such as predefined goals or fixed timelines. It is a continuous process where relations are constructed with a wide range of stakeholders and flexible time and resources.

We argue that a strategic ‘connector-integrator’ role of design would actively work towards bridging the gap between the stakeholders involved by creating the right environment for the collaboration, and maintaining the infrastructure. We believe that such an infrastructure is better placed within a university led model and not a government or industry one, nevertheless, the model must be unlike the ones such as the Tripple helix.
Engagement Models for Social Innovation

Historically models such as the triple helix support innovations, with Industry-Government-University collaborations looking at delivering three-way value (Ranga, M., 2015). Nevertheless, due to its limitations the triple helix model is now considered out-dated and alterations are being proposed to this traditional model to suit it to the post-modern needs of innovation. Wise and Høgenhaven (2008) suggest that there is a need for a paradigm shift where innovation models are concerned. According to them the role of users within innovation is growing, and all new models of innovation must include engagement of user communities. Many argue that mere inclusion of ‘users’ would only allow niche innovations that are product based, and commercial in character; and social innovation would need wider participation from different societal groups.

One such example depicting the limitation of a typical triple helix model was the HiCS (Highly Customized Solutions) project that also presented yet another alternative multi-stakeholder collaboration. The projects under HiCS were funded by the European Community 5th Framework Programme, focused on the topic ‘food for people with reduced mobility’, and initiated a collaboration between European enterprises (TNO, Philips), and university research communities (based in Politico de Milano, Cranfield University). Manzini, E., Collina, L., & Evans, S. (2004) concluded these projects as solution oriented partnerships, which focused on creating cross disciplinary, cross sector connections, resulting in co-production of sustainable solutions; i.e. Manzini’s designing for communities process. Whilst these collaborative projects were designed to create several partnership-based case studies, they also created innovative sustainable solutions. An interesting aspect of this European commissioned collaboration was the initiation of a bigger role for the ‘citizen/people’, nevertheless their involvement was limited (Valota, P., 2014), demonstrating a collaboration that was unequal. Undeniably, this suggests that Manzini’s designing with communities an important missing link for the HiCS project.

Scholars such as Eriksson et al. (2005), Yawson (2009), Lundvall et al. (2002), and Thomke & von Hippel (2002) have constantly proposed including the ‘users’ as the fourth pillar to the triple helix, as they believe that most innovation should be user-centred and account society as an equal stakeholder. The inclusion of the fourth pillar as the citizen/user/public gave way to the emancipation of an alternative helix known as the quadruple helix. These multidisciplinary and multi-stakeholder models for innovation have created a new opportunity for the inclusion of the citizens/people as a participant within a social innovation project. Therefore, most traditional models of innovation including quadruple helix are now under threat, by the rise of the need to make use of models, which allow for decentralized, distributed, and user-centred innovation processes, and outcomes.

Whilst the positive impact of university led social innovations have been documented Goddard, J. (n.d.), alternative models illustrating different ways in which student groups and design could be mobilised to have an impact on society, and respond to, or indeed begin to solve social problems have not been investigated.

Role of Design in Creating Multi-Stakeholder Value

The challenge associated with all the above types of systems is that they are always
evolving, and trying to fit the requirements of multiple stakeholders, giving rise to disconnected engagement (Lundvall, B.-Å., 2010). Lundvall, B.-Å. (ibid.) and Nelson, R. R. (1993) put importance on the common values, and common purpose shared between the producers, and users of knowledge within such projects. In order to ensure that any system generates value to all stakeholders there is a strong need for an objective entity to play the role of a ‘connector-integrator’.

One such example can be seen in the social innovation methods created by Philips Electronics (Design) through projects such as “Chulha” (the design and manufacture of a wood burning stove) using a philanthropic approach (Philips, 2008). This was an outcome of a program started by Philips Design, which aimed at aligning the company’s corporate social responsibility programme with its integrated strategy for brand leadership, strengthening employee engagement, increasing trust and customer loyalty, while developing new ways of working and in time creating (co-creatively) innovative solutions. Under the particular ‘philanthropy’ program at that time Philips focused on the problem of indoor pollution caused by biomass fuel in open cookers in rural India.

In order to understand the socio-cultural aspect of the problem space the design team at Philips saw that it had to collaborate with a local sustainable development agency named ‘Green Earth’; their first stakeholder. Further, Philips investigated the local infrastructural facilities, products and production facilities, and distribution channels for existing stoves, and for this they collaborated with a non-profit organisation named ARTI, entrepreneurs, and self-help groups such as SEDT (Socio Economic Development Trust); their second stakeholder. The addition of citizens as their third stakeholder set this project apart as a potential social innovation as compared to the HiCS project. Philips used a design-led approach to involve citizens in the focus group discussions and co-design workshops; an all-round participatory design approach. The project led to the creation of two versions of the stove locally called ‘chulha’. These products were created locally in collaboration with the local entrepreneurs and social enterprises, and were also co-created with the citizens, bringing value to all involved stakeholders, highlighting the true value of a design led approach to multi-stakeholder engagement. However, since Philips Design played led the project process, the outcome of the project was centred to commercial benefits. The knowledge created was solely for the use of the organisation, therefore the project fell short of having a clear social impact; a key limitation of such projects if not led by the university.

Methodology

For each of the three projects data was collected on process, methods, tools and approaches to innovation. Involved students, clients, and other stakeholders were interviewed, and student activity logbooks were reviewed. Analysis of data focused on finding the extent to which design methods and design techniques had been used to identify and bring together the key stakeholders and empower citizens within the framework. Close consideration was given to student teams’ recognition of key stakeholders for a given project and their identification of shared and discrete value.

Analysis and Findings

The analysis identified four-core design-led activities, which were used to engage the key stakeholders namely, observe and understand, interpret, represent and engage and communicate. Additionally, a stakeholder framework was created for each case study,
which was later consolidated into what we refer to as the ‘creative consortia’ (Figure 1).

In the three cases, four key stakeholders were represented, although, the student teams recognised key stakeholders early on in the project, not all stakeholders identified were actively engaged throughout the project. The framework, illustrated the stakeholders who should be engaged in different phases of a project for social innovation, and therefore indicated gaps in the project strategy. The next sections discusses the value of the four identified activities in engaging stakeholders, and through the case studies describes the value created for each stakeholder.

Key Activities for Stakeholder Engagement

Once in multidisciplinary teams the students in their connector-integrator role went through four activities to identify, and manage, stakeholder expectations within the social innovation context. These four activities of stakeholder engagement, which do not occur as a linear process but happen simultaneously where at certain moments one activity becomes dominant, were:

*Observe and Understand:* Using numerous design research techniques to generate a collection of primary and secondary data, numerous fragments to illustrate different people’ perception of the problem space. The data was focused on understanding the ‘beneficiaries’ of the social change (primarily citizens but also considering the gains or losses of other connected stakeholders). As new systems, services, products, events and policies were proposed, this activity helped the students to consider the dynamic amongst stakeholder positions.

*Interpret:* This activity evidenced student teams using interpretation by applying multidisciplinary perspectives to turn stories and data fragments into opportunities, leading to future ideas. They often used storytelling to make arguments compelling, to test and strengthen ideas, and to prepare a communication strategy to support the project pitch.

*Represent:* This activity entailed students creating and exemplifying ideas visually and
dynamically. Multidisciplinary thinking was evidenced in developing ideas specifically for project setting (its community members and organisations) by developing ideas into business propositions and strategy. Key philosophy underlying student activity is that all stakeholders’ viewpoints are given equal weightage and no one stakeholder emerges as the main owner of the outcomes.

Engage & communicate: This activity encompasses a variety of students and stakeholder co-creative engagements. Typically these engagements were workshops designed to shape the shared value using design techniques to enable the contribution of all stakeholder types. Special care was given to represent all the project voices, while being mindful to those who were least influential.

Case Study 1: Low Simonside

Context

Low Simonside Community Association, who is responsible for the future of the local community’s assets, faces a challenge as council funding is reduced and withdrawn. They reached out to the Multidisciplinary Innovation (MDI) group to explore new service opportunities they could provide to help and engage the community. Their questions to the MDI academics and students were: How can we use our resources to deliver new services and enterprise opportunities; what sort of services would attract current non-users; and, how can we better deliver existing services?

Stakeholders and Value Creation

Students identified three main stakeholders for the project – the Community Association, the Community Centre and the community (benefactors) themselves. In later stages of the project students also involved the second stakeholder, the government, but evidence indicates that these local government employees were not active participants in the project, instead they were used as providers of information, which helped the student teams in strengthening their ideas.

Figure 3 indicates that the project space was mostly used to get a better understanding of the community, and communicate the new knowledge to the Community Association. The Low Simonside project delivered clear impact in terms of organisational stimulation, where the Low Simonside Community Association identified the needs of the community, and established ways in which they could have a wider impact.

The three-week project did illustrate the value of this approach for raising enthusiasm and confidence, informing understanding and supporting planning for the transfer of responsibility of community assets from local authorities to community associations more broadly.
Challenges

The student team identified a set of stakeholders that represented the make-up of creative consortia, however, this set of stakeholders were not brought actively into the project space. This project did not set out to influence policy or the council/community relationship more broadly across the region. Nor did it set out to generate any significant research value, and create opportunities for further funding; nevertheless, the project provided a good opportunity for student engagement and learning.

Case Study 2: Town of Colour

Context

Town of Colour was initiated by a multinational corporation looking into building a manufacturing unit in the Ashington area in the North East of England. Ashington, predominantly a poor community, has a history of disengaged ‘citizens’. The corporate was looking to create awareness for their brand within the community, and approached MDI to identify opportunities for creating engagement, services or community enhancements that would allow direct engagement of the people of Ashington. Their questions to the MDI academics and students were: How could corporate social responsibility engage with the people/citizens of the community? How could a social engagement project raise more awareness of the brand within the community?

Stakeholder and Value Creation

The student teams identified key stakeholders in the first phase of the project, the company, the community, and government, evidencing good practice of connecting different stakeholders. Figure 6 illustrates the engagement level of different stakeholders in different phases of the project.
The project evidenced high level of engagement of three-stakeholders in the different phases: Phase one and two - the community (society), the university and the company; and Phase three - the community, the university, and the local government.

It shows that the community, the primary stakeholder, was involved in all the three phases. In fact, in phase three, the community engagement was most prominent, resulting in opportunities of more empowerment of the community.

Unlike Low Simon Simonside, Town of Colour demonstrated that design has an important role to play as a creative lead in a complex project, and also illustrated that design had the capability to bring different institutional stakeholders together. As a facilitator-connector, design, through the university, in the role of academic-student teams and academic-innovator in residence researchers, established and creatively stimulated the stakeholder setting leading it toward socially innovate futures, and strengthening it as a creative consortium.

**Challenges**

While this project evidenced exemplarily stakeholder engagement (three stakeholders), the connection was discontinuous. The interaction with the local government was also very limited, and they were not well incorporated within the project process, leading to them being observers of the impact instead project participants. Additionally, none of the university’s research groups were involved in any of the phases of the project; hence no research grants or new long-term research collaborations were established. Whilst the project proved to be a great opportunity for student engagement and learning, it did not involve the university, beyond better informal relationships between the university and local business, developing knowledge or new methods ‘value’, which the stakeholders could use beyond this specific project.

**Case Study 3: Percy Hedley Foundation**

‘Able 2’, part of the Percy Hedley Foundation, offers day services and a training ground to adults with physical and communication disabilities. They provide training opportunities in cooking, wood and metal work, ceramic products, handicrafts, digital and print media etc.,
therapies such as physiotherapy and salt therapies, and other community services.

**Context**

Percy Hedley Foundation approached the MDI team and student cohort to help them explore business opportunities emerging from Able 2 as new social and commercial ventures and enterprises for their adults. Their questions to the MDI academics and students were: How can Able 2 transform itself into, or to support, social enterprise without compromising the value its services bring to its service users? What other services could Able 2 provide to its users and the community to support enterprise?

**Stakeholders and Value Creation**

Figure 8 illustrates the stakeholders who were engaged in the project space, the company (Able 2 & Percy Hedley Foundation), the service users (citizens), and the service buyers (local stores and broader public). The stakeholders predominantly involved only these two-stakeholders i.e. the society and the industry; nevertheless, the in-depth engagement with the service users, and service buyers by the students enabled them to propose ideas that were immediately applied within Percy Hedley.

Due to the success of the first phase, the project was extended, and now a direct collaboration with the Percy Hedley Foundation Board of Governors has been established. The Percy Hedley Foundation has approved funding and a research assistant has been appointed to take the research conducted by the student’s forward, and few of the outcomes of the second phase are discussed here (Spencer, et al., 2016).

Unlike Low Simonside, and Town of Colour, the project with the Percy Hedley Foundation has established two strong stakeholders, the university through its research group, and the client through Percy Hedley Foundation’s endorsement on the next phase. An emerging objective of this work is to develop positions and evidence to petition, and we hope co-develop this with government on employment policies in the future.

**Challenges**
Percy Hedley set up a longer-term collaboration that, in the end, involved multiple stakeholders from the Government; and, this was unachievable in the other two projects. However, with the increasing involvement of stakeholders from the Board of directors and Government, the project moved into the domain of academic research, hence reducing the function of the multidisciplinary student cohort in the project. Nevertheless, the role of the multidisciplinary engagement was fulfilled by the academic partners who were from both design and business backgrounds.

**Conclusion**

This investigation focuses on university led collaborations that aim at enabling social innovation. We documented and analysed three projects undertaken by multidisciplinary student teams, which focused on social innovation issues. Evidence confirmed four design-led activities, running through an eight-step process, undertaken to engage project stakeholders and empower citizens, achieved by creating non-hierarchical environments for facilitated co-creative discussions. The projects produced community and company stimulation underpinned by creative, and innovative examples, and strategies for community development and change. The evidence suggests that these projects create or strengthen social relationships through, the mutual recognition of the value each stakeholder group has to offer and gain through their positive involvement, and the shared desire to realise better futures by addressing questions deemed by all sides to be important.

The measure of these projects is the increase in appetite for change and the improved coordination of community members. However, the three cases studied fell short of the ambition of the creative consortium. The creative consortium requires a fundamental change in the way we view and approach collaborative project engagements.

University led social innovation projects within the creative consortium require:

- Representation and active participation of the social setting’s stakeholders, from each element of the consortium, within the project space united by a common purpose.
- The means and mechanisms to transform a stimulating project into action for change. Evaluations of resource, network and funding need to be undertaken prior to a project commencing to establish readiness for social action and the scope of change within a network’s means. This might result in funding applications being establish as the goal of early project activity.
- Projects to be undertaken at a scale that can demonstrate and evidence value that is applicable and scalable to regional and national policies.

Within creative consortia, multidisciplinary students, as a connector-integrator needs to:

- Creatively stimulate the stakeholder setting so that common goals and hopes are uncovered; ideas and plans are expressed and developed; obstacles are identified and means to overcome them considered.
- Empower citizens with decision-making, voting rights and autonomy; an environment that is non-hostile and non-hierarchical; and the tools to both, contribute and develop ideas, and to prototype and communicate them.
- Lead toward socially innovative futures by materialising and visualising progress, prototyping the collective vision and illustrating the roadmap.

Our findings indicate that universities, especially the design disciplines are able to advance learning through partnerships with creative consortia in order to improve, transform, and create new ways of working. In this consortium the university’s learning and teaching,
research groups, strategic level business and engagement agendas are all connected through the student project space to generate value (Anonymous, 2016). At this institutional level, the creative consortium can develop four-fold value with each new social setting: (1) meaningful public and commercial engagement; (2) insights into and scalable solutions for social issues; (3) research about the role and value of design as a contributor for social innovation; and (4) valuable experiences with real projects and face-to-face interactions with clients, for our students.

**Acknowledgments**

We would like to extend our special thanks to Low Simonside Community Association, Percy Hedley Foundation and Town of Colour associates for the opportunity. Special thanks to our very capable research assistant Laura McKay for her hard work. Lastly we would like to thank the MSc/MA Multidisciplinary Innovation cohort of the academic year’s 2013 and 2014 for their hard work and resilience.

Author Biography

Steven Kyffin
Professor Steven Kyffin was appointed Pro Vice-Chancellor (Business and Enterprise) in September 2016, having previously been Faculty Pro Vice-Chancellor for the Faculty of Arts, Design and Social Sciences since September 2012 and Dean of Northumbria School of Design since January 2010. He has a Master of Design, Industrial Design, Royal
College of Art London and a Hon Doc of Civil Law from Northumbria University. Of the past thirty years, Steven has spent ten in the London's Design consulting businesses; ten in academia, including Director of Industrial Design at the Royal College of Art and prior to joining Northumbria University, Steven spent ten years in Corporate Design leadership as Director of the Global Design Research group in Philips Electronics.

Mersha Aftab
Currently lecturer in Innovation at the Department of Design, Mersha Aftab started working with Northumbria University, in June 2012. She has a Masters in Design Management and a doctorate in Design from Northumbria University. Mersha joined Philips Design as an intern in 2010 under a collaborative scholarship scheme between Philips and Northumbria University. In 2013 she was awarded her doctorate in the topic ‘design as a functional leader: a case study to investigate the role of design as a potential leading discipline in multinationals’. Mersha’s work has led her to collaborate with Nokia, Daimler, Sony Erricson, Lego, Google and Samsung. Mersha’s interest lies in exploring the role of design in triggering a change in the culture of organisations.

Nicholas Spencer
Nicholas is Programme Leader for the MA/MSc Multidisciplinary Innovation programme. In this role Nicholas helps to develop international educational partnerships that develop new forms of innovation for external commercial and third sector organizations through novel academic, student and community co-creation. Nicholas' first degree is in industrial design and his Doctorate focused on expert designers' experience of practice. Teaching design research into the Design Department's Postgraduate provision and supervising Doctoral Research programmes supports and is supported by the personal research focus of developing new understandings of networked design intelligence.
Interaction between client and design consultant: The stance of client to design consultant and its influence on design process

Haebin Lee, Muhammad Tufail, Myungjin Kim, KwanMyung Kim
Graduate School of Creative Design Engineering, Ulsan National Institute of Science & Technology, Ulsan, Republic of Korea

Abstract

Design is essential in product development but several small and medium-sized enterprises (SMEs) relatively capable of manufacturing are suffered from lack of in-house design ability. For new product design, these SMEs typically employ external designers. In this client-designer interaction, designers propose design solution alternatives to their clients, which clients may accept or reject. In some cases, clients provide designers further design requirements. A study on how interactions are performed and what effects these interactions have on the results of product development is essential to determine what is needed to achieve successful collaborative relationships. Thus, this study analyzed three design development cases that were previously performed to understand how interactions work between clients and designers and its effect on the outcomes. In all cases, the design team developed designs for the clients based on their technological requirements. This study focused on the effect of client stance on the process and deliverables. Clients usually take various actions that accept or reject design solutions or give additional demands. This is because clients take initiative in decision making. Clients' stance was divided into receptive and expressive stances. As a result, a receptive stance ensured the design capabilities of design consultants, whereas expressive stance confined design capabilities to some extent but a new design direction may be proposed based on a client's knowledge, information, and judgment.

Keywords: client-designer relationship, collaborative design, product development, client stance

Designers in consulting firms are engaged in product design development for clients. Many product design works performed by designers include both exterior design and interior structural design. In this setting, product design is essentially achieved through collaborative processes between engineering and industrial designs (Horvath, 2004; Hosnedl et al., 2008; Hubka, 2013; Kim & Lee, 2010). Thus, designers should consider various elements such as a product's exterior, interior, operating structure and parts, and use scenarios.

In this regard, large conglomerates where product development actively takes place frequently operate their own industrial and engineering design teams. However, SMEs that attempt product development for the first time or individual inventors will face great difficulty during product development in general. It is normally important for

those companies without design teams to utilize external designers to gain competitive advantages as a business strategy (Bruce et al., 1999; Filippetti, 2010; Lewis & Brown, 1999; Von Stamm, 1998).

The relationship between designer and client, particularly for SMEs, venture entrepreneurs, and individual inventors, may simply be a commissioner-deliverer relationship. However, it can be a co-work relationship instead. It is, thus important to understand which co-work relationships exist and what is the effect of a co-work relationship? When designers co-work with colleagues from other fields during the design development process, they find it difficult to communicate with them since they have different expertise (Kleinsmann & Valkenburg, 2008). In the product development process, designers and other experts may have different knowledge and experiences, which cause conflicts (Kim & Lee, 2014). This can also be applied to the relationship between designers and clients. The present study focused on this perspective and investigated the type of cooperation between client and designer and its effects. As such, three collaborative design projects under designer-client relationship and how different interactions affect the outcomes were analyzed.

**Research framework**

The case projects were conducted from 2014 to 2016 between our institute's design team including the authors of the present study and three different SMEs. These projects aimed to develop products that had potential market entry based on the ideas, technologies, and patents of each company. The first case project was conducted in 2014 in which a mechanical-based recliner chair was developed proposed by the client. The second case project was conducted in 2015 - a multi-functional baby carrier based on another client's initial design. The third case project was conducted in 2016 in which a radiation shielding garment was developed for a client company who have developed radiation shielding materials. The common points in these three were: (1) a process of typical technology-based product development based on technology devised by a client, (2) the number of employees at each SME less than five persons, and 3) the first time startup of attempting product development through design.

In each case project, an attempt was made to produce design deliverables that satisfy the clients' requirements and marketability. Clients and our design team made continuous interactions for the whole product development processes. For the analysis, the interaction data such as meeting data, interview data, exchanged information, etc. was collected with clients particularly focusing on clients' attitude towards the design team.

Basically, the designers' perspective is formed in a contract relationship that completes the requested design and delivers it to the client. Even if clients and designers are in a good cooperative relationship, designers should continuously propose design solutions, whereas clients accept or reject them or demand further design requirements. This becomes interaction that affects the design execution of design consultants by their actions; this is because clients generally have the right to decide. Accordingly, the present study aims
to determine the effect of clients' stance towards designers and changes in stance on design deliverables.

Clients' stance was analyzed from two viewpoints. First, an expressive stance in which the client wants to express their ideas or intentions continuously to exercise their influence on the design team, and second a receptive stance in which the client accepts and recognizes the opinions of the design team. According to Gericke and Maier (2011), the cooperative modes of interaction between a client and design consulting team can be divided into two parts to understand whether a client participates in the design process. The first part can be passive coupling where the client leaves all processes and decisions up to the design team completely, and the second part can be active coupling where designers from the client side actively participate in the design team. As such, the design projects here are based on passive coupling because clients did not actively participate in the design process. However, it is still not genuine that clients do nothing even in a passive coupling relationship. For example, clients constantly interact in the design process by providing necessary information, delivering requirements, evaluating, accepting, rejecting, or re-persuading with the design solutions proposed by designers. In general, the design team proposes a design solution to a client, and the client then accepts or rejects the proposal. Clients provide information for the design team or make specific demands. In summary, the stance is divided into two parts: The expressive stance where the client's stance is to express their ideas or intentions continuously to exercise influence over the design team, and the receptive stance where clients accept and recognize the decisions made by the design team. Some examples of expressive stance are the cases in which clients do not accept the designers' proposal, and provide further information to the design team to fulfill their intention, or put forward their own draft to modify and revise the design elements. Receptive stance includes agreeing and accepting the design solution when the designer proposes a draft or accepting the designer's draft in recognition of the designer's expertise even if the client do not agreeing with.

**Analysis of case projects**

**Case 1: A recliner chair design project**

This project aimed to design a new recliner chair that could be launched in the market based on the client's technical patent of a mechanical mechanism. Initially, the client provided drawings, patent specifications, and test prototypes (See Figure 1). In fact, the client's recliner technology was based on a mechanism where a chair back plate was pushed back when a user exerted a certain amount of force in the preferred direction, and a seating plate and back plate pushed the user when the user wished to mount up from the chair.
Firstly, the design team analyzed the drawings and the test prototype provided by the client and then the recliner chair market was analyzed where user study was conducted. Based on the received data, the design team reconstructed a chair structure using three-dimensional (3D) computer-aided design (CAD) to create design alternatives. However, the design team suggested possible improvement of the structure because it was excessively complicated, thereby losing some competitiveness against the existing products, and users were vulnerable being thrown forward upon while getting up from the chair. Nonetheless, the improved structure was not adopted because the client rejected it on the grounds that the patented technology should be applied to create differentiation. The design process was then started on the exterior design over the main frame based on the 3D CAD data, and the design team produced three design proposals as shown in Figure 2.

Type A and B were simple designs because they maintained the original internal mechanism, whereas Type C modified the internal structure into external visual elements while maintaining the working principle in the internal structure, resulting in a significant modification from the original configuration. The design team preferred to decide the final proposal based on market analysis, but the client who received three drafts adopted Type A to suit their preference. In particular, the client expressed strong opposition against Type C, which showed a unique shape that outwardly revealed the internal structure. During the process, the client did not adopt any new mechanism as proposed with innovative elements or a unique shape such as Type C did, but selected Type A according to the client's preference.
The client's stance revealed during the design development process can be depicted through expressive and receptive stances as shown in Figure 4.

As explained above, the client desired to intervene in the overall process. A part from the moment of accepting Type A (marked with a receptive stance in Figure 4), the client took a consistently expressive stance where no improvement drafts proposed by the design team were accepted. In particular, the client strongly wished to select the preferred design rather than an appearance style based on the opinions of design experts and market surveys. The client's stance prevented the design team from additional in-depth ideation, which made innovative design development difficult resulting, the design team's capabilities limited. The reasons for the client's consistent expressive stance were (1) the client's strong insistence on a specific exterior shape had placed the client's intentions above the decisions made by the design team and (2) the client judged that competitiveness ensured via the use of the patented technology was more advantageous than improving the product. The client was holding the final decision rights, due to which the client's intention was ultimately applied in the design. This project was a case where the design team and client disagreed each other.

Case 2: Multi-functional baby carrier

This project aimed to develop a product design based on the client's patent composed of a
baby carrier that could transform into a wooden horse rider. Initially, the client provided the design team with operating structure, patent, test prototype, and use scenarios (See Figure 5). Since the test prototype was out of sorts for a commercial product, the design team initiated a complete overhaul of the test prototype.

The initial design provided by the client had a structure that changed mode between baby carrier and wooden horse rider by rotating a hip seat (See part 400 in Figure 5) via pushing the wooden handle down (See part 500 in Figure 5) that was inserted in the main body. In the market, most baby carrier products are composed of textile material rather than a rigid body to ensure the safety and comfort of the baby. However, the design proposed by the client did not consider such elements, which had resulted in an unsophisticated structure as a commercial product. Furthermore, rearranging the parts to change the mode required a cumbersome process, generating significant inconvenience. Accordingly, design team created a totally different design solution from the original design proposed by the client as shown in Figure 6.

In Figure 6, the mode can be changed between baby carrier and wooden horse rider immediately using a shoulder band while wearing the baby carrier. In addition, it was composed of a textile material to increase comfort. The client stance towards the design team regarding the proposed design was neutral-to-somewhat-negative. Nonetheless, the client accepted the new design solution, as the design team convinced the client based on user test studies and product reviews. Thus, it was significantly improved from the original design.
The client's stance revealed during the design development process of Case 2 can be depicted as both expressive and receptive stances (See Figure 8).

The inventor, who was a representative of a corporation, provided the initial design solution to the design team and requested to closely follow (expressive stance). However, the analysis results conducted by the design team concluded that the design the client had proposed would not be competitive in the market. Therefore, the design team proposed a new structure, shape, and use method. The client initially responded to the design team's proposal negatively. However, the other members from the client side had baby carrier use experience and accepted the design team's idea. Accordingly, the inventor reluctantly accepted the new design proposal. The design team developed a final design solution based on the proposal, which was confirmed by the inventor. Later on, the inventor received product reviews from potential customers acknowledged that the decision made by the design team was genuine.

The series of processes can be explained in terms of the client stance as expressive stance followed by receptive stance. One important note in this case is that how the company representative who made important decisions could change his stance from expressive to receptive. The change in stance was possible because a colleague whom the representative, the inventor completely trusted took a receptive stance and convinced the inventor at all. If a colleague of the inventor had not taken a receptive stance or another colleague who was not trusted by the inventor took a receptive stance, the inventor might have not accepted the design team's proposal as found in Case 1.
Case 3: A radiation shielding suit design project

This project aimed to develop a new radiation shielding garment by using the client's company's own shielding materials. The radiation shielding material developed by the company was flexible and easy to fabricate with high shielding performance against radiation.

Initially, the client provided the design team material samples and related information. The design team conducted studies on radiological workplace, users, and market surveys to identify opportunities for the design development of radiation shielding garments. Radiation shielding garments should be equipped with a vest and genital protector to protect the internal organs and genitals, which are the most vulnerable areas to radiation. Currently, existing shielding garments used in South Korean nuclear power plants are heavy and inconvenient, because they often place lead blocks in the vest. Furthermore, radiological sectors are divided into three zones according to the amount of potential radiation exposure. The workers must wear different types of shielding garment at each zone. Basically, a worker has to use three different types of vests when moving from a place with low radiation to a medium and high radiation zone.

The design team sought to overcome these problems by proposing a new design with better workability and more comfort than the existing radiation shielding garments. Thus, it was required to provide attachable vests that did not require additional shielding garments for different working areas when moving between the three different radiation zones. The new design also has increased usability and cost effectiveness due to its modular design and reduced waste materials. Existing radiation shielding garments required each amount of material for the types A (light), B (middle), and C (heavy). However, the modular design only needs an amount of material used in type C, which can shield the most radiation as it is attachable whenever a worker travels from a low- to a high-radiation zone. Figure 9 shows the design solution. In contrast with conventional products in which the thickness of lead blocks differs according to the required radiation shield amount, the design proposed by the design team has a basic type (the two upper left images in Figure 9) that is used for zone 1 (the low-radiation environment), and two modular types (two upper right images and two lower images in Figure 9) that can be added on the basic type in zone 2 and 3 as the amount of radiation increases.
Although the client firstly accepted the design solution proposed by the design team for further development, the client later requested for changes in design direction in the middle of the process, providing potential merit in medical equipment markets. The radiation amount generated by medical equipment such as X-ray imaging or computerized tomography equipment is relatively constant and easy to shield against radiation. Therefore, medial radiation shielding garments do not need modularization. Since medical radiation shielding garments often need to protect the hands of workers, thus the client also requested the development of a wristlet protector. The design team acknowledged it and the design direction was changed to develop a medical shielding suit design (Figure 10).

The client did not intervene in the design process much compared to the client in Case 1, and took a receptive stance overall. In the middle of the design process, the client took an
expressive stance by demanding a change in the design target because of the product potential in the medical market (See Figure 11). The client then took a receptive stance regarding the design developed by design team during the development of the medical shielding suit following the client's request. This stance helped the design team ensure autonomous activity.

Figure 11: Client stance changes in Case 3

**Insights from the case studies**

The case studies show the effects of the client's stance during the interaction between clients and the design team and are summarized below:

1. *Expressive stance*: The intervention of clients without justifying the views of design team can disturb the design development by limiting the design team's capabilities. However, reasonable intervention by convincing the design team can help them come up with new design alternatives.

2. *Receptive stance*: This provides an environment where the design team can sufficiently exhibit their capabilities.

Case 1 is an example of a client taking a constantly expressive stance. In this case, the design team made constant efforts to persuade the client but unsuccessful. The clients continuously intervene in the design process and stand on their preferred design solutions regardless of the market study or the design consultant's recommendation. Thus, the capabilities of design team become limited and could not produce a final solution. In such a case when the client takes an expressive stance, it is necessary for the design team to persuade the client with rationales. Otherwise, the design results may satisfy neither the client nor the design team.

In Case 2, the inventor as a corporation representative initially took an expressive stance, but changed to receptive in a dramatic manner. Similar to Case 1, the inventor initially requested to accept the ideas. However, one of the inventor's colleagues accepted the design team's proposal and convinced the inventor's stance to a receptive one. Although the inventor's stance was still expressive against the design team's proposal and acknowledged flaws in the initial judgment after receiving the final design solution and supportive product reviews from the real users.

Basically, clients have to argue in a cooperative relationship; however the design team should play the role of persuaders. If the design team cannot convince the clients, the results will not be successful in case if a client continuously insists to select a design that the design
team find difficult to accept. Therefore, persuasion and communication should be a two-way process; this is particularly apparent if a client takes an expressive stance. Changing a client's stance from expressive to receptive stance requires removing a barrier from the client's mind. Thus, the design team should understand the barrier of the clients who have taken an expressive stance, and persuade them. The ability to persuade clients can also be regarded as one of the design team's social skills. In contrast, a client should give credibility to the proposals of design consultants, which may be advantageous in terms of the design team's performance.

The client in Case 3 took a receptive stance. Thus, the design team's design choices were not limited by the client's intentions, but were able to progress the design process freely. Clients temporarily changed to an expressive stance during the development process when they discovered another potential market entry point. Although limitations or changes in design direction can burden the design process due to unknown and subjective knowledge, ideas, and judgments by clients through an expressive stance. It can also lead to product improvements and innovation that may be missed by the design team. In such interventions, the validity of the clients' judgment and how reasonable the logic behind their judgment is are both important. Since the client in Case 1 continuously intervened in the process based on its personal preference, which limited the designers' capabilities, whereas the client in Case 3 intervened in the process by providing sufficient knowledge and information that designers could implement the new design direction.

**Discussion and conclusions**

It is difficult to conclude that design process and results are affected positively by client's stance in the cooperative design development process under client-designer relationship. The outcomes of the case projects have not yet launched in the market. Thus, the effect of the expressive or receptive stances taken by the clients in the design processes cannot be known for the design outcome in terms of commercial success or market acceptability. Nonetheless, the present study showed how the client's stance during the design process can influence both the design process and outcome.

The present study investigated the client's stance within the passive coupling relationship (Gericke & Maier, 2011), in which the clients had no design expertise or capabilities. Although the client's intervention in the design team's work can help the design team recognizes what may have been missed in the design process as shown in Case 3. It can also limit the designers' capabilities, thereby preventing the design team from achieving the best outcomes. However, active coupling (Gericke & Maier, 2011) where designers from the client side participate in the design process with design consulting company may have a different effect to the expressive and receptive stances in contrast with the case of passive coupling. That is, since clients have a higher degree of understanding about the design project in active coupling, it can reduce the negative effects of an expressive stance. If clients are excessively consistent with a receptive stance, the design team becomes vulnerable to neglecting practical factors such as productivity or price, which may be a problem in terms of the potential implementation of the final design although this is not discussed in the above cases.
However, better design results can be achieved if design team recognizes new information when the clients provide sufficient information and positive influence with an expressive stance.

Although the present study specifically discusses the relationships between clients and the design team. The insights can be applicable to the relationships between superiors who make decisions and the designers of in-house product development teams. That is, any relationship between a superior and designer in a product development team at a company can be compared to that between a client and a consulting designer. It may have a different effect on the design process and outcomes according to which stance a higher organization or superior takes with a product development team; this presents an interesting subject for future study.

Furthermore, interactions between teams in product development projects where several teams collaborate are also regarded as taking expressive or receptive stances. Kim and Lee (2016) argued that idea exchanges between design teams are frequent when different fields of expertise are discussed, and the efficiency of the design process or quality of outcomes can be affected by the stances that different teams initiate. For example, an engineering team may take a receptive stance that accepts an exterior design proposed by an industrial design team in the process of product development without any objection, or take an expressive stance in which they demand modifications or reject the proposal. When an engineering design team takes a receptive stance, an industrial design team may show their capabilities to the fullest. However, if an engineering design team takes an expressive stance, an industrial design team may be limited and take a receptive stance, or take an expressive stance by opposing the design proposed by the engineering design team. In reverse, an industrial design team may take a receptive or expressive stance regarding a specification proposed by an engineering design team. Such a relationship is horizontal, as neither team has the absolute decision right, in contrast with the relationship between clients and design teams, where most decisions are made by the clients. Therefore, a study on the effect of stance between partners in design process management for the design process and outcomes will be an interesting subject.

Overall, the insights from the case studies can provide basic guidance for exploring the effect of stance between partners in the design process and outcomes in various types of cooperative design development processes. It can also provide hints about which stance should be taken by a client while cooperating with designers during a new product development process based on technologies. For designers, this study furthers specific guidelines about how to respond to a client's stance in collaborative settings of a client-designers relationship.

KwanMyung Kim
KwanMyung Kim is an associate professor at Graduate School of Creative Design Engineering UNIST and a director of Integration and Innovation Design Lab. He received his Bachelor's, Master's and PhD Degrees in Industrial Design from KAIST, Daejeon South Korea. With 14 years of industry experience, he intends to bring practical knowledge on design and design engineering in academic research. He is interested in combining and generating design and engineering knowledge that lead innovative and practical outcomes through design research. Currently, his research interests include design-integrated innovation, innovative product development, and integrated design process.
Breaking through Fuzzy Positioning: Diverse Design Communication Strategies for Older Adults’ Healthcare Wearables

Chen Li, Graduate School of Design, National Yunlin University of Science and Technology, China, fionalee1125@qq.com

Chang–Franw Lee, Graduate School of Design, National Yunlin University of Science and Technology, Taiwan, leecf@yuntech.edu.tw

Abstract

In this study, based on the perception of older adults, fuzzy positioning of healthcare wearables and impacts of differentiated product positioning on human considerations and design communication strategies are studied. Empirical researches are performed by adopting both quantitative research (248 questionnaires for clustering and regression analysis) and qualitative research (15 cases for in-depth interview). The perceptions of older adults on product positioning are divided into three types: Tech-Aid, Fash-Acc, and Fash-Tech. Results indicate that the influential human considerations for each positioning were different from each other. Through coding and storyline analysis, diverse communication strategies are found for each positioning. The outcomes for each type are as follows. For Tech-Aid, wherein older adults lay emphasis on usefulness, ease of use, and privacy, the designers can adopt a calm communication strategy by giving priority to older adults’ control power, fitting symptoms, user-friendly, and cautious interconnection. For Fash-Acc, wherein older adults focus on personal image, aesthetic appearance, and ease of use, an active communication strategy for modeling a style for elderly fashion that agrees with aesthetic appreciation and simplified operation can be adopted. For Fash-Tech, wherein older adults require to integrate usefulness, ease of use, aesthetic appearance, comfort, privacy, and self-image, a persuasive communication strategy can be used, through which designers can offer older adults more data insights and entertainment, along with data association, and in the meantime, reduce data interferences and pay attention to style modality and appropriate display with context fusion and contact comfort.

Keywords: Healthcare Wearables, Older Adults, Product Positioning, Design Communication, Human Consideration, Design Elements.

In recent years, accelerated social aging causes older adults to improve their demands of healthcare, life assistance and independence. The wearables attach great importance to health self-management and medical association of local older adults. However, practical cases that older adults make use of the wearables for healthcare are still very limited despite that designers deem that such a design is able to bring independent and safety to older adults in their daily life (Dickinson & Hill, 2007). In other words, it is difficult for them to accept them. Thus, the researchers start from perceptual product positioning of healthcare wearables, then explore the influential human considerations and communication strategies for design, the
following problems are presented here:

- Do older adults have different recognition tendency and agreement towards the positioning of healthcare wearables?
- What influences does the perceptual positioning have on human considerations which are related to acceptability?
- Which communication strategy should be taken specific to each positioning of healthcare wearables?

**Literature Review**

**Fuzzy Product Positioning for Older Adults**

Research hot spots related to the present healthcare wearables are involved with how users treat such new product positioning (Choi & Kim, 2016; Rauschnabel et al., 2016). Among them, an interesting issue is that wearables fall into the type of medical technology or fashion accessories and how to treat fuzzy boundary between such two types of positioning. Product positioning is a critical part of product decision and closely related to ultimate physical characteristics and the perception nature of design (Kaul & Rao, 1995). The essence of product positioning cognition difference is rooted in the differences in perception of categorization. In accordance with the categorization research about consumer psychology, categorization is a mental process during which individuals make their quantities of life experiences structured by classification construction and description (Loken, Barsalou, & Joiner, 2008). On this basis, it can be inferred that categorization different from the previous can be generated among older adults so as to further affect clear and definite product positioning of healthcare wearables, as far as conflicts between new medical technology inherent in the devices and the corresponding acquainted appearances. For older adults, diverse categorization and product positioning absence have an impact on their perceptions on benefits incurred by the related design, especially when the boundary between medical technology aids and fashion accessories is involved.

**Human Considerations to Acceptability in Wearable Interaction**

Considering the research of Buenafior and Kim (2013) about human considerations to acceptability and some other research about older adults, this paper first puts emphasis on influences of human considerations related to cognitive, social and physical aspects on the wearable interaction design.

**Human considerations in cognitive aspect:** (1) Perceived Usefulness (PU): Utility is a problem of design and also an essential value of devices (Ledger & McCaffrey, 2014). PU means that older adults consider utilizing particular devices to improve degree of healthcare performances. Although the wearables with complex sensors may not be fully interpreted by older adults, the emphasis of design communication can be exerted on how to prove the design is able to truly improve health benefits of older adults. (2) Perceived Ease of Use (PEU): In terms of older adult technologies, ease of use, as a non-ignorable basic principle (Czaja & Sharit, 2013; Fisk, Rogers, Charness, Czaja, & Sharit, 2009), is put on an important position by studies on mobile technologies (Renaud & Van Biljon, 2008). PEU refers to
mental and physical efforts taken by particular devices in the opinion of the elder users. As the wearables is a type of intelligent technology, considerations about older adults’ difficulties in learning and perceiving them affect the ease of use of related products and services.

**Human considerations in social aspect:** (1) Personal Image (PI): Personal image means that a particular healthcare wearables is able to offer older adults with a self-identity feeling suitable for overall identities and status of them on one hand; on the other hand, it determines that whether such a particular healthcare wearables is able to improve the status of relevant older adults in social system (Moore & Benbasat, 1991). Most of healthcare wearables are exhibited in forms of clothes and accessories that are exposed in social environment surrounding these older adults. Therefore, it has a more significant influence on appearances of older adults than other technology products. (2) Personal Privacy (PP): Evaluations between practical values and privacy risks emerge with the development of information technology. In line with privacy calculus model (Dinev & Hart, 2006), users are willing to give up some privacies (e.g., personal information) to acquire certain benefits (individualized services). However, the role that privacy plays in health wearable interaction for older adults, that is still not clearly discussed, has been incorporated into considerations of this paper.

**Human considerations in physical aspect:** (1) Aesthetic Appearance (AA): Aesthetic experience is a critical part of healthcare wearables (Lin, Chien, & Kerh, 2016). Perception of older adults on particular design features in the process of healthcare wearable design can coordinate the design so that aesthetic preferences of the elder users are comprehended more thoroughly. (2) Physical Comfort (PC): Tehrani and Michael (2014) points out that wearables are electronic technique or computers that can be put on comfortably and this is the uppermost feature of wearables; in addition, comfort of the healthcare wearables including clothes, etc. has an important influence on consumers’ decisions (Kaplan & Okur, 2008). As wearables for health monitoring requires wearing for a long time, the corresponding comfort cannot be overlooked.

**Research Methods and Procedure**

Based on explorations in relevant theoretical background, we proposed three hypotheses: First, differences lie in older adults’ perceptions on product positioning of healthcare wearables. Second, product positioning may have influence on influential human considerations to acceptability. Third, dependent on different kinds of perceptual positioning, design elements related to influential human considerations in interactive contexts would be different from each other.
Then, empirical researches were performed by adopting both quantitative and qualitative research studies (please refer to Figure 1). Tested objects of this study are urban older adults who are interested in the healthcare wearables. In quantitative phase, relevant data are collected here by questionnaires that should use scales with good reliability and validity in references as bases to the greatest extent. Questionnaire surveys are also carried out to gather data and SPSS 24.0 is adopted to perform data analysis. The Crobanch’s $\alpha$ value of 248 effective questionnaires as a whole is 0.90 (>0.70), and relevant results indicate that the KMO value is 0.87, sphericity test of Bartlett exhibits significant results ($p<0.001$), which proves that the questionnaires surveys have preferable reliability and validity. In qualitative phase, case study was adopted to explore critical design elements and adaptive communication strategies of the wearable interaction design under the circumstance of the perceptual positioning of them. During interview, the older adults put on device of the same type as stimulus material to obtain the firsthand experience, see Figure 2. Grounded theory was utilized as a methodology and QSR NVivo 11.0 as an analysis tool to assist with data processing of interview recording for 15 older adults.

**Discussion**
Cluster Analysis of Perceptual Product Positioning

From the beginning of analysis, Two-Step Clustering from SPSS is also employed to perform cluster analysis on stimulus materials. Research results of cluster analysis indicate that 248 testing results are divided into three clusters (87 cases for Cluster 1; 53 cases for Cluster 2; and, 108 cases for Cluster 3) to obtain an excellent cluster quality. Mean values of product positioning perception and lifestyle items in three clusters (see Figure 3) are both comprehensively analyzed in detail here:

**Figure 3.** Mean results of cluster analysis: (a) mean value results of product positioning perception; (b) mean value results of lifestyle

**In Cluster 1, which is named as Tech-Aid (TA) type,** older adults have a high degree of recognition in medical technology, while low in fashion accessory. It signifies that technology assistive capability of wearables is considered to be very important by older adults from this cluster. Then, lifestyles of older adults are further analyzed and it turns out that they share some features such as poor physical conditions, daily exercise occasionally, fewer social contacts than other clusters, and more technology consumptions than those of fashion.

**In Cluster 2, which is named as Fash-Acc (FA) type,** older adults have a high degree of recognition in fashion accessory, while low in medical technology. It signifies that fashion values of wearables are deemed to be very important by older adults from this cluster. Then, most significant lifestyle features of older adults in this cluster include good physical conditions, most daily exercises, most social contacts among three clusters, and higher identification degree of fashion consumptions than technology consumptions.

**In Cluster 3, is named as Fash-Tech (FT) Type,** older adults have high degrees of recognition in both medical technology and accessory, which proves that they pay close attention to combined actions of technology abilities and fashion values. Among older adults from FT type, evident lifestyle differences lie in the fact that not only do they have optimal physical conditions, but similar identification degrees of fashion and technology consumptions.

The Influential Human Considerations in Different Product Positioning
This research focuses on estimations on healthcare wearable design with diverse types of product positioning. The mean values of influence human considerations show that three types of product positioning are similar to each other in terms of physical characteristics. However, as far as cognitive attitudes and social interactions are concerned, they are dramatically different (see Figure 4).

![Figure 4: The mean results of human consideration on each product positioning](image)

The mean values of design factors also clearly show different perception degrees on every stimulus sample. Nevertheless, it is difficult to carry out deductions in a wide range due to influences of stimulus sample selections. Therefore, this study pays much more attention to the potential influence relations between variables. In this process, PU, PEU, PI, PP, AA and PC are all used as independent variables, BI as a dependent variable, to perform multiple regression analysis. As for related data obtained, please see Table 1. According to coefficient of determination of the regression equation, such coefficients of three regression equations are all greater than 0.50. Thus, these multivariate regression results can be utilized to conduct detections correspondingly in this paper, see Table 1. Significances of standardized regression weights in three groups serve as basis for discussions below:

**For TA type positioning**, PU, PEU and PP are significantly related to acceptance behaviors. To be specific, PU ($\beta = 0.668***$) has the most important influence on such behaviors, followed by PP ($\beta = 0.265**$) and PEU ($\beta = 0.260**$) successively. **For FA type positioning**, factors significantly related to acceptance behaviors are PEU, PI and AA. In detail, AA ($\beta = 0.418**$) has the most important influence on such behaviors, followed by PI ($\beta = 0.334**$) and PEU ($\beta = 0.297*$) successively. **For FT type positioning**, all factors explored during study are significantly associated with acceptance behaviors of older adults. Clearly, Fash-Tech type positioning is a fusion of medical technology and fashion accessories, which differs from Tech-Aid type and Fash-Acc type positioning. Corresponding data results indicate that PEU ($\beta = 0.379***$) has the most important influences, followed by AA ($\beta = 0.228**$), PC ($\beta = 0.215*$) and PU ($\beta = 0.207**$) take the third place while PI ($\beta = 0.199*$) and PP ($\beta = 0.161*$) come last. On account of this data with diverse influential human considerations of product positioning, it is unnecessary to define which type of product
positioning is the best as each type is specialized and has its own strong points.

Diverse Communication Strategies based on Grounded Theory

Dependent on the aforementioned difference in human considerations affecting the adoption of healthcare wearables of diverse types of product positioning, it is deemed in design study that grasping product positioning defined for the healthcare wearables as well as essential human consideration for each kinds of positioning is the first critical step. Meanwhile, understanding the interactive context of communications between influential human considerations and design elements adopted by the designer is another critical step to probe into adaptive design communications continuously in a qualitative phase. In this part, grounded theory was utilized as a methodology and QSR NVivo 11.0 as an analysis tool to assist with data processing of interview recording for 15 older adults. Free Nodes of NVivo was employed for open coding encoding according to Vivo encoding principle, and Tree Nodes for axial coding related to each kind of positioning. Thus, the common encoding book could be obtained with reliability of three researchers arrived at 72%. Furthermore, Model was also utilized to connect axial codes to describe the interactive development story line between human consideration and all design elements.

A Calm Communication Strategy for Tech-Aid (TA) Positioning

Encoding of TA positioning came from five interviewees. In total, 95 free nodes were sorted out and then used as the open codes converged into 21 axial codes. Settlement of the storyline, axial codes of PU, PEU and PP were used as the center to construct the interactive contexts between them and other axial codes. After Storylines analysis in in TA positioning, a calm
communication strategy is proposed, explorations were made centering on PU, PP and PEU which have the greatest influence on the adoption of the older adults, see Figure 5.

(1) **Priority to control power; Fit symptoms.** Starting from PU, it was found that design element that has the largest impact on usefulness was Control Power. The design should endow the older adults with a sense of accomplishment that they had the ability to control by themselves and the age of physical condition recording in a passive way has ended. Furthermore, older adults who gave the devices TA positioning usually have more experience in and are more concerned chronic diseases, especially high cholesterol, high blood pressure, high blood sugar (Three-higos) problems regionally commonly seen.

(2) **Friendly learning; Straightforward.** As far as PEU is concerned, the factor that has the largest influence on the ease of use is Learnability. During interviews, it was found that the older adults indeed became nervous at the time of wearing devices and they were also not accustomed to too much learning. It is much likely for the older adults to accept wearable parts of easy operation.

However, some old people do not want to learn to use smart phones and thus hope that devices are able to fulfill measurements and get command of enough health information independently. Then for older adults who use wearable parts or smart phones, their expectations to Readability and Interoperablity can be traced back to Visualizing Data. In other words, they hope that the devices can be provided with clear large characters that are easy to understand and can be seen by just raising hands at the time of using smart watch.

![Figure 5: Storylines in TA positioning](image)

(3) **Information hierarchy; Cautious interconnection.** PP is identified by the older adults
from three levels: personal data, measurement data, and personal experience. Older adults hope to reveal such information to the least extent, while be only willing to talk about them with experienced friends or interconnect with doctors, and share their healthcare experience with any one and hope that more people can benefit from it. As a result, at the time of considering privacy problems of wearables, the designer should start with data type identification and rationally arrange disclosure degree of data in diverse types, so that reasonable privacy arrangement can be made on the basis of meeting interactive intentions of the older adults.

An Active Communication Strategy for Fash-Acc (FA) Positioning

Encoding of FA positioning came from four interviewees. In total, 170 free nodes were sorted out and then used as the open codes converged into 25 axial codes. Settlement of the story line, axial codes of PI, AA and PEU were used as the center to construct the interactive contexts between them and other axial codes, see Figure 6. After storylines analysis in in FA positioning, an active communication strategy is proposed, explorations were made centering on PI, AA and PEU which have the greatest influence on the adoption of the older adults:

(1) **Thinking about modeling; Concealing stigma.** The most influential code of PI is Modeling Implication. In interview, health monitoring function deliberately displayed on devices by designer becomes a burden to the older adults. With aging and the arrival of diseases, the older adults begin to play a minor role in the entire social so that they become especially sensitive to senses of identity. If the design is accompanied with a stigma of “Old Patient”, older adults can be ashamed of displaying such wearables. In comparison, they are more willing to show those beautiful ones. Besides, the older adults of this positioning have many social contacts and they expect to maintain personal images of being healthy and active in Social, Data Connection and Experience Exchange.

(2) **Modeling style, Agreeing with aesthetic appreciation.** An important relation exists between Modeling Implication and Visibility, and AA. The older adults hope that these wearables could be accessories that look normal and can be exposed as usual. Additionally, Style is also a factor that should be taken into account as far as beauty is concerned. Older women may expect wearables to be strongly decorative on behalf of their pursuits for beauty. By contrast, older men prefer smart watch and expect the corresponding products to be high-end, but not over high-profile.
(3) Simplified operation; Popping on and off at will. Starting from PEU, the most evident code is Interoperability. It is apparent that the older adults pay less attention to health monitoring functions of such wearables than appearance and self-image. Simplification of Operation Steps on interoperability to reduce operation levels is indispensable. If the design is able to provide an Abnormal Reminder by voice interaction, the corresponding devices can become very convenient for the older adults; furthermore, the older adults also need to pay less attention to them. Moreover, they also keep a watchful eye on the process of popping on and off, for it is less likely for them to put on these devices frequently. In order to develop a habit of wearing for a long time, it is necessary to take multiple scenarios in their life into consideration.

A Persuasive Communication Strategy for Fash-Tech (FT) Positioning

Encoding of FA positioning came from six interviewees. In total, 219 free nodes were sorted out and then used as the open codes converged into 26 axial codes. Settlement of the story line, axial codes of PU, PEU, PI, PP, AA and PC were used as the center to construct the interactive contexts between them and other axial codes, see Figure 7. After storylines analysis in in FT positioning, a persuasive communication strategy is proposed, explorations were made centering on PU, PEU, PI, PP, AA and PC which have the greatest influence on the adoption of the older adults:
Figure 7: Storylines in FT positioning
(1) **Data insights; Entertainment complementary.** PU is a human consideration that has the largest influence on adoption. Implications of data can be explored in a more thorough manner on the basis on Health Assessment so as to offer more specific Health Tips. Although data are readable for the older adults, the older adults also hope that Health Tips can assist them with healthcare. Expansions to the Entertainment function are also offered to the older adults. In this case, the power of health behavior can be improved by virtue of competitions among people and radio function is also incorporated into the device to increase their willingness to put on it.

(2) **Visual data to reduce interferences.** From the perspective of usability, Readability of data plays a critical part. The core technique of wearables should be closely associated with data monitoring. Therefore, Visualizing data is a necessary design element, including static data, dynamic data, characters and charts. Use procedures of various data interleaving in the device may make the older adults confused. During interview, there are still many old adults who do not know the meanings expressed in the curve chart and they hence hope that auxiliary characters can be provided clearly on the screen.

(3) **Style modality; Appropriate display.** The context of PI gets involved with Color, Modeling Implication, Scale and Style. according to the context of original texts, those the older adults keep saying over and over again are liberality and reserved as far as color, size, modeling and visibility are concerned. The older adults need the design to conform to their identities without over highlighting their own images. As for the color, they prefer low-profile dark colors. Nevertheless, they expect the wearables to meet their aesthetic tastes; and, the integral shapes of them look delicate and nice.

(4) **Professional people, Data association.** At the level of PP similar to TA positioning, the older adults interviewed are concerned about protection of Personal Information Connection, despite that they prefer Data Connection. As for the concrete crowds of association, they consist of professional doctors, wellness counselors and friends, etc.. With an aim to obtain more effective design suggestions by data association, the designer pay more attention to the specialty of crowds associated in the process of design.

(5) **Appropriate size; Proper style.** It was found that design elements involved with AA always turns up in accompany with PI. Although no direct causal association has been found between them, they are still closely related to each other. Design elements contained in appearance are Style, Scale and Visibility. Taking smart watch as an example, the older adults pay attention to lighter modeling of smart watch, a right ratio between the watchband and the dial plate, as well as its novel and concise style. All these aesthetic tastes properly display their ages.
(6) **Context fusion; Contact comfort.** In terms of PC, the older adults deem that they should feel comfortable with wearables as soon as they are touched. In addition, the older adults also pointed out that the Contact Surface should be ventilated, light and possess a simultaneous loose-tight property so that no special senses can be generated after they put on them. Especially in winter and summer, breathable and skin-friendly materials should be selected for the contact surface, including dermal and cotton fabrics, to ensure Context Support and also guarantee that the older adults can put on them comfortably.

**Comprehensive Discussions**

Based on influences of human considerations related to devices of different kinds of positioning on the design element at qualitative and quantitative research stages, it is deemed in this study that at the very beginning of design, product positioning should be defined and followed so as to distinctly go back to life styles of the target older adults and considerations about human considerations. On this basis, both designers and developers could figure out diverse design communication strategies by making positioning of healthcare wearables clear to improve the adoption of the older adults in the development plan. Calm strategy suggests using passive healthcare interactive mode to give priority to older adults’ control power; While, active strategy suggests using more peripheral interaction during healthcare, such as voice interface, appearance and social cue; At last, persuasive strategy suggests being a healthcare companion, amplifying the best of technology and the best of humanity.

**Conclusion**

Through empirical studies on samples in a large size, two important findings are further put forward based on data results. First, older adults’ perceptions on product positioning of devices are classified into three types, including Tech-Aid type, Fash-Acc type and Fash-Tech type. Second, product positioning developed for older adults in a particular lifestyle should be definitely judged to designate an effective design communication strategy. In concrete, Tech-Aid type puts emphasis on perceived usefulness, ease of use and older adults’ personal privacy. Designers can take a calm communication strategy by giving priority to older adults being active, fitting symptoms, User-friendly and cautious interconnection.; while, Fash-Acc type stresses older adults’ personal image, aesthetics appearance and ease of use of devices. An active communication strategy is adaptive by modeling style for elderly fashion, agreeing with aesthetic appreciation and simplified operation It emphasizes privacy preferences and personal image preferences. As for Fash-Tech type, perceived usefulness, ease of use, and aesthetics appearance of devices should be integrated in combination with living habits of older adults. A persuasive communication strategy can be used, through which designers can offer older adults more data insights and entertainment complementary by data association, but reduce data interferences and pay attention to style modality, and in the meantime, appropriate display with context fusion and contact comfort.

**Author Biography**

**Chen Li**

Chen Li is currently a doctoral student at National Yunlin University of Science and Technology (YunTech). She has a bachelor’s degree and a master’s degree in industrial design from Beijing Institute of Technology (BIT). Her areas of interest are technology acceptance in older adults, wearable design, and designing for special populations.

**Chang-Franw Lee**

Chang-Franw Lee (PhD) is a Professor in Graduate School of Design, National Yunlin University of Science and Technology (YunTech), Taiwan. Professor Lee was previously Chairman of the Department of Industrial Design (1999-2002), Director of the Graduate School of Design (2003-2010) and the Dean of the College of Design, YunTech (2011-2016). Currently, he is the Dean of the Office of Academic Affairs, YunTech. His research interests include Ergonomic Design, User Interface Design, and Universal Design.
Re-clarifying Design Problems through Questions for Secondary School Children
An Example Based on Design Problem Identification in Singapore Pre-Tertiary Design Education

Abstract

It is believed that secondary school students often define design problems in the design coursework superficially due to various reasons such as lack of exposure, inexperience and the lack of research skills. Questioning techniques have long been associated with the development of critical thinking. Based on this context and assumption, the current study aimed to explore the use of questioning techniques to enable pre-tertiary students to improve their understanding of design problems by using questions to critique their thinking and decision-making processes and in turn, generate more effective design solutions. A qualitative approach is adopted in this study to identify the trajectories of students during design problem identification and clarification process. Using student design journals as a form of record for action and thoughts, they are analysed and supplemented by hearing survey with the teacher-in-charge. From the study, the following points can be concluded: 1) questions can be a useful tool to facilitate a better understanding of the design problem. 2) The process of identification and clarification of design problem is important in the development of critical thinking skills and social-emotional skills of the students. 3) It is important that students are given time and opportunity to find out the problems by themselves. 4) Teachers can be important role models as students may pick up questioning techniques from teacher-student discussions. 5) Departmental reviews and built-in professional development time for weekly reviews on teaching and learning strategies are necessary for the continual improvement D&T education.

Keywords: Design Education; Questioning Techniques; Design and Technology; Critical Thinking

The process of design, on one hand may be understood as a process of rational problem solving (Simon, 1973; Coyne, Rosenman, Radford, Balachandran & Gero, 1990; Liikkanen & Perttula, 2009) and on the other, a process of reflective practice (Schön, 1983, 1987). Design and Technology (D&T), studied as a general education subject in Singapore secondary schools, engaged students with the full range of design activities that span from identifying design problems to the production of solutions in the form of working prototypes. One of the challenges for students towards proposing an effective solution was to clearly understand the design problem before moving into ideation and development of the solutions.

A common technique used to clarify design problems include mind mapping,
conducting field research and interviewing potential stakeholders. General feedback from teachers is that students are looking for the wrong type of information that is not related to the design problem. Also, due to the lack of research skills, students are passive and often dependent on teachers to provide instructions in clarifying design problems. In some cases, in the name of students’ inexperience, teachers resort to telling students what the design problems should be instead of allowing students to explore and understand the problem by themselves.

Questioning techniques have long been associated with the development of critical thinking skills. Using Bloom’s Taxonomy as a basis, asking higher order questions will require higher order thinking in the form of analysis, synthesis and evaluation. In addition, the skilful use of convergent and divergent questions may facilitate decision making, expansion, exploration and creativity (Elliot, Kratochwill, Cook & Travers, 2000).

It is in this context and assumption that the current study aimed to explore the use of questioning techniques to enable pre-tertiary students in improving their understanding of the design problems by using questions to critique their thinking and decision-making processes and in turn, generate more effective design solution.

**Design Problems in the Design & Technology Coursework**

It is widely agreeable that nature of design problems are complex, ill-structured with ambiguous goals, without a determined solution path and required the integration of multiple knowledge domains (Reitman, 1965; Simon, 1973; Jonasson, 2000). According to Goel and Pirolli (1989), problems involved in design contain many degrees of freedom, required substantial information collection, problem structuring and negotiation. Much of the information required comes from external sources or prior experience of the designer (Goel & Pirolli, 1989). In addition to the understanding of design problems, a design problem may evolve throughout the design process thus making it hard to identify (Dorst & Cross, 2001; Dorst, 2006). In the design coursework, students usually engaged in design problems with little ‘design experience’. Although students are trained in problem solving skills in other subjects, most of the commonly encountered problems are well-structured. In handling design problems, students required a different set of problem solving skills to explore into the ill-defined and ambiguous design situations and eventually proposed the most effective and plausible design solution within their own defined constraints.

**Questions and Critical Thinking**

**Critical thinking and the Process of Design**

Critical thinking is thinking about one’s thinking process; it occurs when a person evaluates reasoning used in coming to a conclusion (Moore & Parker, 2015). According to Butterworth and Thwaites (2013), critical thinking is about making informed evaluative judgements about claims and arguments. As a process, critical thinking may involve three main activities, namely, analysis, evaluation and further argument (Butterworth & Thwaites, 2013). As an ability, critical thinking involves the
capacity to assess and apply evidence to support or evaluate an argument (Watson & Glaser, 2008). In addition, critical thinking can be considered as a rigorous process of inquiring, learning and acquiring knowledge for the critical analysis and evaluation of evidence to justify one’s belief (Ikuenobe, 2001). As a critical thinker, several skills are believed to be necessary, such as, interpretation, analysis, evaluation, inference, ability to clarify, decision-making and problem solving.

In the process of designing, critical thinking is very much involved right from the process of identifying and clarifying design problems to the conceptualisation of a suitable solution to the production of the prototype. Whether design is treated as a rational problem solving process or a reflective practice requires the designer to interpret the information related to the design problem so as to propose and evaluate all possible and effective solutions.

**Questioning in Thinking Process**

According to Chin and Langsford (2004), questions can to some extent influence the level of thinking operations that students engage in. Questions may be classified into various categories as such:

- Lower and higher order questions according to different levels of thinking (Bloom, 1956)
- Open and closed questions (Blosser, 1995)
- Productive questions (Elstgeest, 1985)
- Operational questions (Alfke, 1974)

In associating questions with critical thinking, it is believed that questions that require higher order of thinking, such as a) inference from patterns, trends or underlying relationships in data, b) predict outcomes and c) evaluate and use criteria based on given information to make judgement, are pitched at critical thinking level (Chin & Langsford, 2004). While questions that involve, a) formulating alternative hypothesis from same observations, b) planning and designing experiments for investigation using tests and c) proposing and generating solution to a problem, invoke creative thinking skills (Chin & Langsford, 2004).

The relationship between questioning and thinking can be understood according to Ikuenobe’s (2001) analysis on how the process of questioning, for the purpose of eliciting information and justifying one’s belief, is necessary for critical thinking. To think critically involves the ability to question and evaluate beliefs, so as to justify and approximate the ‘truth’ (Ikuenobe, 2001). It is through the process of critically evaluating and questioning a number of evidence that one would then move on to make the judgement that there is adequate evidence to consider it reasonable (Ikuenobe, 2001). Similarly, Siegel (1988) argued that critical thinking involves the acceptance of a belief, based on reasons, after a rigorous process of questioning.

**Questioning creates understanding**

Ikuenobe (2001) explained that the process of questioning is very much a sequence of
open-ended question and answer, where in this open-ended process, one question may lead to another. It is through this process that issues can continuously be opened-up about the reasonableness of a belief and requires the providence of better evidence and counter evidence. This attitude of critically engaging in inquiry though the process of questioning can be learned if one is taught to appreciate the logic, functions and significance of questioning with respect to knowledge acquisition. Hintikka (1984) argued that questioning offers a useful model for different types of knowledge seeking. These types of knowledge-seeking may include learning, inquiry, eliciting information, reasoning, evaluating evidence and determining reasonableness of a belief (Ikuenobe, 2001).

It appeared that questioning already has a strong research base across disciplines (Duke & Pearson, 2002; Sternberg, 1998). Questioning as a form of thinking, according to Wilson and Smetana (2011) can be a framework for comprehension of expository text and content across content areas. In the process of learning, through questions, a person may make use of questions to independently monitor and regulate his/her thinking. Questioning in turn guide the use metacognitive actions and the answers to the questions may inform the person of the metacognitive task necessary for learning.

**Research Methods**

**Scope of Study**

The current study looks into a typical secondary two D&T coursework in a Singapore secondary school. As D&T is only an elective subject at the secondary three and four level, the D&T programme at secondary two level may provide a better reflection on the types of design activities that most of the secondary school students would have gone through in their secondary school education. As the current study aimed to focus on the design problem clarification aspect in the design process, the process of design problem identification and clarification of design problems will be identified and analysed.

**Participants**

The participants in this study came from a class of 41 secondary two students in an autonomous secondary school in Singapore. The D&T programme in this autonomous secondary school is widely recognised by the local D&T fraternity to be well established among the secondary schools in Singapore. At secondary two level, the students are generally around the age of 14 and will have prior D&T knowledge based on the initial study of D&T in secondary one. Throughout the design coursework, students were grouped to work in pairs although most of the processes were to be done as an individual work. During a discussion with the teacher teaching the class for D&T, it was understood that not all of the work done by students present a good representation of D&T learning in the class. Some of the works done by students were lacking in documentation on the processes which provided a challenge for accurate analysis. Some students were not able to produce good quality work due to heavy commitments in other school activities. Out of the 41 students, work done by nine students were selected as representatives of the typical D&T work done in the class. The grouping were as follow: Group 1, Group 2, Group 3, Group 4 and Group 5. It should be noted that Group 5 consisted of only one student. The grouping of students is as shown in Table 1.

Procedures

During the design coursework, students record their course of action and thoughts into the design journal. Besides, students often have individual consultation sessions with the teacher-in-charge so as to allow the teacher to understand the challenges that the students are facing and also to guide the students.

As such, the current study is based on a qualitative approach that aims to analyse and understand the design problem identification and clarification trajectories that the students have taken during the design coursework. The main piece of data that is analysed in this study is based on the design journals done by the students. From the journals, the analysis mainly focuses on the process of design problem identification, and particular attention is placed to review how the usage of questions may enable students to clarify their understanding of the design problems.

Although it is understood that the design journal may not be able to provide a 100% record of the design problem identification process; verbal feedback and discussions with the teacher-in-charge provide essential supplementation to the information that may not be recorded in the journals. As such, interviews with the teacher-in-charge are conducted throughout the data analysis process.

Research Findings

Overall View of Coursework Tasks

The secondary two D&T design coursework spread over 14 weeks with a 2-hour lesson each week. The students engage the design coursework in pairs but due to the odd number of students in the class, one of the students worked as an individual. The main stages in the design coursework include:
1. Identification of Design Problems

Although students are grouped to work in pairs, they are required to work on stages 1, 2 and 5 individually. They submit their work related to the three mentioned stages as individual work.

The Flow in Identification of Design Problems

In the stage of design problem identification, given a theme, students start off with brainstorming to scan and identify possible design problems. There is no restriction on the type of strategies that students can use during the brainstorming process. The underlying rationale is that there is no single approach towards the identification of design problems. As such, students can make use of any strategies they know during the brainstorming session.

From the brainstorming process, students then move on to select a few prospective design problems for further clarifications. It is after this clarification that the members of each group come together to decide and select a design problem to engage further as a group. Just before moving into the Idea Conceptualization stage, students work as a pair to conduct further research to facilitate idea conceptualisation. This flow of the process is presented in Figure 1.

At this point, some details should be mentioned during the further clarification stage
for selected design problems. In this process, a critical thinking template is created by the D&T department to help students critically assess their perceptions and understanding of the chosen design problems. The critical thinking template is created due to the observations and experience from D&T teachers in supervising design coursework in the previous years. From those observations, the D&T teachers observed that in general, students’ understanding of design problems are superficial. As students are low on exposure and life experience, perspective and understanding of the design problems are mainly based on their prior knowledge or experience. In addition, there is also no habit of critical inquiry and research to find out and understand more about design problems.

Based on the concept of Paul and Elder (1996, 2002) on strategies for critical thinking, the critical thinking template is a template that requires students to clarify three main questions,

1) Is the problem or needs clear?
2) Is my thinking accurate?
3) Is my thinking only from my point of perspective?

The critical thinking template adopted some of the universal standards, as suggested by Paul and Elder (1996, 2002), that can be applied to check the quality of reasoning about a problem, issue or situation. The universal standards used in the template are related to, Clarity, Accuracy and Breadth. It must be noted that the first use of the template was in 2012 and the original template contained more standards than the current version. However, according to the teacher-in-charge, students are not able to handle and work on so many universal standards at one go. As such, only three of the standards that are deemed to be most achievable and useful for students to critically assess their thinking in the current context are used.

Within each of the main questions in the template, students are required to come out with sub-questions to guide themselves during the clarification process. In the end, students are required to redefine the problem or needs identified. Figure 2 shows a sample of the critical thinking template used in the design coursework.

Moving on to the next part of the finding, the design problem identification and clarification trajectories of the students is presented. The main focus is to highlight the use of questions to clarify and understand selected design problems and lead to the decision-making process in selecting the design problem for further engagement. The presentation will be divided into two main parts, 1) Brainstorming session and 2) Selecting and further clarification of design problems.
Brainstorming Session

In the brainstorming session, students started off to explore possible design problems. It is observed that students employ two to three main approaches in general. These methods are mind mapping, problem-solution analysis and a hybrid of mind mapping cum problem-solution analysis.

In the use of mindmaps, it is observed that the quality of exploration differed among students. For example, referring to Figure 3 and 4, in the exploration done by student S1A, the areas of interest are listed followed by short notes. Whereas for student S1B, she made use of questions that start with *How, What, Why, Who* and *Where*, to guide the exploration process.
It can be observed from the mindmap that student S1B jotted down deeper thoughts into the journal as compared to her partner where the exploration of design problems are more superficial. At this point, it is necessary to highlight that, through the questions, student S1B tried to provide the rationale behind the various aspect of the design problem which may bring about better understanding of the design problem.

For students who approach the brainstorming session using problem-solutions, students mainly identified possible problems and tried to suggest certain solutions to the problems. Some examples of such approach are presented from Figure 5 to 8. A common observation found in these three examples is that the design problems, which is the main aim for exploration, are quite briefly analysed by the students. All students tried to state the main perceived problems, but all failed to provide at least some basic
underlying reasons to justify the problems that they perceived are in fact problems.

Figure 5: Exploring possible design problems through problem-solution by student S3A.

Figure 6: Exploring possible design problems through problem-solution by student S3B.
Figure 7: Exploring possible design problems through problem-solution by student S5A.

Figure 8: Exploring possible design problems through problem-solution by student S4A.

Figure 9: Exploring possible design problems through problem-solution by student S2A.
It seems that the lack of depth in understanding the main cause of the design problems and providing reasonable justifications to support their claims are common among students. In fact, such similar observations can also be observed for students who tried to brainstorm and explore problems using the hybrid between a mindmap and problem-solution analysis, refer to Figure 9. Such observations may suggest that the depth of understanding of design problems does not hinge on the types of approach but may be related to the ‘way of thinking’, in other words, the habit of the mind to critically assess one’s thought and believe.

Selecting and Further Clarifying Design Problems

As it is expected that students might not be able to critically assess and evaluate their perception and belief about a certain design problem, the critical thinking template was introduced as an intervention to ‘facilitate’ students to look into the ‘matter’ more critically. It appears that the critical thinking template does have some effects on students who have initially explored the design problems very superficially. As the whole, when students re-define and re-write their design problems, improvements in clarity and depth can be observed across all the students. While the level of improvements varied among the students, this study did not go into a more specific analysis to detail the specific level of improvements in each student. An example of the critical thinking template, when done by students, is shown in Figure 10.

Figure 10: Exploring possible design problems through problem-solution by student S1A.
Though improvements can be observed in general, the critical thinking template seems to have a magnifying effect on students who are already ‘good’. For example, for student S1B, who is already able to explore the design problem with quite some detail, the template seems to help the student to elicit more information and inquire more critically into her own reasoning process. At the same time, expanding the breadth of her critical thinking process as she seeks other perspectives through research related to the problem. An example of the critical thinking template and research done by student S1B is shown from Figure 11 to 15.

Figure 14, shows an extremely long redefinition of the design problem or needs. In fact, student S1B wrote about her findings and analysis of the design problem instead of describing the design problem concisely. While students are required to redefine their design problem concisely, nonetheless, this information provided a form of documentation and evidence towards the quality of her findings.

Figure 11: The original design problem statement and the aspect of clarity about the problem by S1B.
Figure 12: The aspect of refining accuracy and validity of the problem by S1B.

Figure 13: The aspect of seeking other perspectives about the problem. Done by S1B.
Residents have a problem of pamphlets being stuffed between the door gaps. This is basically because there is no holder for the pamphlets. As pamphlet givers are usually very fast trying to distribute the pamphlets to all the houses, they usually find the door gaps a best area to place the pamphlets. As they think that residents can definitely see their pamphlets if it is in the door gaps. Whereas, most residents find it irritating as for the pamphlets. In that case, this problem would be solved if there are pamphlet holders by the door. From one of my evidences who already have a holder at the door. From my experience, it would be better if the residents still get a good look using a simple compartment. It is more innovative and attractive design wise. My evidence prefers it to be a single compartment as it would be too complicated to have many compartments. The residents also do not want it to be too big as it may give an unpleasant look. Looking at the information they are trying to tell us, with pamphlet holders, both parties would get benefited as the residents would not get irritated looking at brochures or pamphlets being stuffed in their door gaps. And pamphlet givers also do not need to roll or fold their pamphlets just to stuff it between door gaps. And it would also be easier and faster for them to distribute the pamphlets as they do not need to waste time folding or rolling the brochures.
For students who had explored the design problem very superficially, the critical thinking template ‘force’ them to look into the problem in more details. An example may be shown from Figure 16 to 18. This is attributed to the sub-questions that they need to ask themselves and at the same time, find out the ‘answers’ to their own questions. In addition, teachers also provide comments and guiding questions when checking students’ journal. Besides, students are also given the opportunity to comment and feedback on their partner’s analysis and understand of the design problem.

Figure 16. A very superficial design problem exploration. Done by S3B.
Figure 17. Assessing different elements of reasoning through Clarity, Accuracy and Breadth. Done by S3B.
Through the sub-questions, students, in general, get to explore the different aspects related to their design problems. It is unsure if students have thought about these questions during the brainstorming and exploration process. However, through the initial design problem statements, where most of the design problems are in a way superficially written by most students, it may be assumed that it is during this stage of critical thinking process that students started to think deeper about the design problem. Perhaps this perspective can also be supported by some of the students’ reflections where they mentioned that the overall design problem identification process had helped them to consider deeper and gain new insights towards the actual needs of stakeholders. In addition, through critically assessing and justifying their perception and beliefs about a certain problem, students are required to be more observant. Part of the extract of student reflections are shown in Figure 19, 20 and 21.

Figure 18. Redefining the problem. Done by S3B.

During the D&T lessons, I have learned many things and values. The first task we were ask to do was listing down problems/situations. Ms [_____] only told us to do fifteen problems. I didn't think that was a hard task as I thought any problem she would accept. However, when I came up to her and she ask me to think of more problems. I was not sure why I have to do more than some other of my classmates.

Hence, Ms [_____] taught us to practised critical thinking which means to think carefully and this really helped me to list down some GOOD problems in the end. Just completed the ‘first stage’ of D&T, I was already quite tired of the subject. Therefore, critical thinking really taught me to think deep and consider about the community needs and wants. There was also a time where I was having difficulty

Figure 19. Extract of the reflection by S1A.
According to the teacher-in-charge, before the use of the critical thinking template, the teacher had gone through a discussion session with the students by giving them some examples of superficial design problems and using questions to guide students in providing more clarity and understanding towards the problems. After the discussion session, students moved on to engage into clarifying their design problems using the critical thinking template. From the sub-questions that students had come up with, it can also be observed that most of the sub-questions are of higher order thinking or open-ended. It is an interesting observation as students have not been specifically trained to ask lower and higher order thinking questions. In a way, students have plenty of opportunities to sharpen their critical thinking skills through higher order thinking questions.

**Discussion**

**Questioning as Tool Towards Design Problem Clarification**

When presented with a design problem, the previous experience and prior knowledge about the problem will naturally be activated to provide an immediate understanding, perception and belief about the cause of the problem. In most cases, students often showed a lack of experience and prior knowledge about the design problems that are identified. In order to bridge the gap between students’ level of understanding about the problem and the reality, the current study has presented evidence to show that questioning can be an effective scaffold to help the students critically assess their
thinking and evidence on hand about a design problem. Subsequently, it leads to the eliciting of information for new knowledge acquisition for the critical analysis and evaluation of evidence to justify their beliefs about the problem. During this critical analysis and evaluation process, students are required to be more observant during their research, and truly understand the issues and needs of the stakeholders. As such, learning takes place.

While the critical thinking template is created to facilitate the process of critical thinking, this template does not aim to get the students to follow a set of procedures or format in doing things. However, more importantly, by going through the process of critical assessment of thinking and reasoning, it is the internalisation of the attitude and ability in using questions in the critical thinking process that is the underlying aim for the use of the critical thinking template. Internalisation, in a sense, is to become part of the thinking habits in the student as a person. In this case, such attitude and ability may be applied across subject domains and may facilitate the development of the student as a life-long learner which is critical in the 21st century. As a general subject, D&T has an enormous potential in this aspect of critical thinking development.

The Importance of Design Problem Identification Process

If it is justified that the process of questioning facilitates and strengthen the development of critical thinking skills, then it may be assumed that the design problem identification process is as important to any other parts of the design process, such as idea conceptualisation and prototyping in the learning of design in D&T. As questions influence the level of thinking operation, the design problem identification process provides a rich ground for the development of higher order thinking skills due to the open and ill-defined nature of design problems.

As it can be observed in the students’ trajectories in identifying and clarifying the design problems, there is no definite answer to the design problems, in other words, no one answer is correct. The answer towards the design problem may evolve as students clarify the design problem is further. As such, the process of critical assessment of thinking and reasoning about the design problem allows students to understand the true nature of the world around them which they may have taken for granted. Additional to developing the cognitive aspect of the students, the process of identifying and clarifying design problems also develop the social-emotional aspect of the student. By developing a better understanding of the problems and needs of people, students may get to have more empathy and heart for people.

Thus, it is imperative that D&T teachers continue to provide opportunities and time for students to critically explore, scrutinise and define their understanding and beliefs about design problems during the D&T coursework. Sometimes, teachers may have the tendency to tell the students what the design problem should be, in the name of helping the students and time saving; such actions may take away their opportunities to learn about our world through design activities.
Teacher as a Role Model

While students are not taught on the theoretical aspect of lower and higher order type of questions, students' ability to ask mainly higher order questions when using the critical template suggested that they may have picked up this skill during the discussion session. As mentioned in the findings, the teacher-in-charge provided some examples of superficial design problems and tried to get the students to think about the actual cause of the problem by asking them questions. In a way, the teacher is setting herself as a role model in using questions for critical assessment, reasoning and evaluating the understanding of the design problems. As such, role modelling, a traditional teaching and learning strategy, can be a fundamental strategy in teaching students how to question during the design problem identification and clarifying process.

The Importance of Teacher Professional Development Time

While the professional development of D&T teachers in secondary school is not the focus of this study, but during this study, the authors believe that the current study may be a good example to highlight the fruits of teacher professional development time in the school. In order to keep the design education relevant, the D&T department holds annual year-end review sessions for the D&T programmes and teaching pedagogies. It is during this type of review sessions that the D&T department teachers, based on their teaching encounters and experience, surfaced issues in the design problem identification process and the challenges that students faced. Through discussions and review of relevant theoretical references, the critical thinking template was conceived and implemented. While an implemented teaching and learning (T&L) framework and strategies required constant reviews, the D&T teachers make use of their weekly professional development ‘white space’ to review the critical thinking template and continue to sharpen the T&L framework and strategies. In other words, design educational programmes, T&L framework and strategies need regular reviews to keep them relevant to the needs of the students. In this sense, professional development time and regular ‘white space’ for educational reviews will continue to be a vital clog for the development of design education at pre-tertiary level. Perhaps, this may also be true for other subject areas.

Limitations to current study

The findings in the current study are based on the design coursework journals and feedback from the teacher-in-charge. Most of the observations and assumptions in the findings are based on the documentation done by the students in the journal. As such, it is also believed that not everything is measurable or observable based on the journals. Language and writing competencies of students may play a part in the ability to document detail findings and evaluations. In addition, some students may not be able to articulate their thoughts that well during the discussion session with the teacher-in-charge. Thus, the journals may only be able to provide a certain resolution towards the understanding of the students’ trajectories towards the identification and clarification of design problems. Besides, the attitude of students also played a part in the quality of the work. Thus, when it is assumed that a superficially identified problem may be due to competencies, in fact, it may be due to the effort of the students.
Another point to note is that journals from previous years are shown to the students for reference. This may also have a certain impact on the quality of work done by students as they are aware of the expectations of the output for their design journals.

Last but not least, during the brainstorming session in exploring possible design problems, the current study allowed students to make use of divergent processes that they are familiar. Perhaps, interventions should be done during the design problem exploration process so that multiple divergent processes may be explored to exploit the effective use of questions to sharpen students’ exploration of design problems during the brainstorming session.

**Conclusion**

In conclusion, the current study suggests that questions can be a useful tool in leading students to elicit information for new knowledge acquisition for the critical analysis and evaluation of evidence to justify their beliefs about the problem. This in turn provides them with a better understanding of the design problem. On top of that, this study further indicates that the process of identification and clarification of design problem is important in the development of critical thinking skills and social-emotional skills of the students. As such, D&T teachers need to provide students with the time and opportunity to find out the problems by themselves. In addition, teachers are also important role models for students as students may pick up questioning techniques from teacher-student discussions. Lastly, departmental reviews and built-in professional development time for weekly reviews on teaching and learning strategies are necessary for the continual improvement and development of D&T education.

**Acknowledgements**

The authors would like to thank Mr Suresh Balakrishnan (Principal-Dunman Secondary School), Mr Julian Liew (Head of Department C&T-Dunman Secondary School) and all who had directly or indirectly involved for their support in this study. We would also like to thank the anonymous reviewers for their invaluable suggestions for improvement of the paper.

**Author Biography**

Wei Leong, Leon LOH
Leon was with the Ministry of Education, Singapore, between 2001 and 2014 where he mostly served as a teacher and Subject Head (D&T) in Singapore secondary schools. Currently, he is with Kyushu University, Faculty of Design, engaging in design education research at tertiary and pre-tertiary level. At the tertiary level, his current research topics include developments of product design education curriculums and quality assurance in design education. At pre-tertiary level, his research topics include a) developing design education curriculums, b) critical thinking and design thinking skills acquisition through design activities and c) learning environment to enhance the quality of design education.

Hwee Mui, Grace KWEK
Grace has been serving as a secondary school teacher in Singapore for 15 years. During this period, she has taken on leadership and mentoring roles such as Subject Head, Head of Department and Lead Teacher. She has received a Master of Design from the University of New South Wales in 2005. Her current work engagements involve mainly
staff development and mentoring programmes. She used to be a member of the Academy of Singapore Teachers (AST) D&T Subject Chapter core team. Her research interest revolves around the development of thinking skills and experiential learning in Design & Technology subject.

Wei Leong, LEE
Lee Wei Leong is a Design & Technology (D&T) Senior Teacher with 14 years of teaching experience in secondary school. Wei Leong holds a Post-Graduate Diploma in Education and a Bachelor Degree (Hons) in Civil and Structural Engineering from National Institute of Education and Nanyang Technological University respectively. He was part of the Academy of Singapore Teachers (AST) D&T Subject Chapter core team between 2011 and 2015. He has also conducted courses for D&T teachers on facilitating students’ design thinking skills through effective questioning. He has also been active in professional and academic sharing on topics related to engaging students in the design process during the annual Singapore Design & Technology Educator’s Society (DTES) conference for the past 14 years.
Speed Dating with Design Thinking: An empirical study of managers solving business problems with design

Seda McKilligan, Iowa State University, Ames, United States, seda@iastate.edu Tejas Dhadphale, Iowa State University, Ames, United States, tejas@iastate.edu David Ringholz, Iowa State University, Ames, United States, ringholz@iastate.edu

Abstract

The concept of design thinking has received increasing attention during recent years, particularly from managers around the world. However, despite being the subject of a vast number of articles and books stating its importance, the effectiveness of this approach is unclear, as the claims about the concept are not grounded on empirical studies or evaluations. In this study, we investigated the perceptions of six design thinking methods of 21 managers in the agriculture industry as they explored employee and business-related problems and solutions using these tools in a 6-hour workshop. The results from pre and post-survey responses suggest that the managers agreed on the value design thinking could bring to their own domains and were able to articulate on how they can use them in solving problems. We conclude by proposing directions for research to further explore adaptation of design thinking for the management practice context.

Keywords: Design thinking; management workshop; innovation process

Design thinking is the way designers identify needs, frame problems and provide solutions through a series of iterative cycles. It’s the thought process of designers in creating product, service and system solutions. There is a strong interest expressed by the business and management communities in using design thinking as they recognize a need to identify strategies for solving complex and open-ended challenges (Stacey, Griffin, & Shaw, 2000). Means for applying and adopting design approaches and processes to management is rather new and not well-defined (Dunne & Martin, 2006; Simon, 1969). Even though the parallels between design and management fields are explored (Boland & Collopy, 2004), design thinking’s integration and effectiveness on management are still vague.

Managers pursue opportunities, incubate innovation, develop new resources, and push their organizations forward. Solving management problems as designers explore and solve design problems – may have important implications for management (Dunne & Martin, 2006).

However, designers and managers’ work flow differ significantly as well as the nature of their tasks. While managers avoid wicked problems and mainly focus on routine tasks, designers focus on wicked problems requiring cross-disciplinary collaborations (Martin, 2005). The question to pose here is how to better integrate design thinking methods into
management to allow for them to immediately see the value and implementation.

Management scholars have been increasingly interested in how innovation challenges can use design methods (Verganti, 2008; Veryzer, 2005) and design practitioners and educators promote the use of design thinking across many areas of business (Brown, 2008; Lockwood, 2010). Despite the increasing amount of research on design thinking, the main focus remains on education cases and the way this thinking process is used in classroom settings for innovation. There is yet much to be done in exploring how practitioners from domains other than design respond to this thinking approach and how they see its integration into their own situations.

Our goals in this study were to assess the value and ease of implementing design thinking methods with managers in the fields outside of traditional design and gain insights on how these methods can be made more practical in the field. Data collection included the pre- and post-workshop surveys, and reflections cards after each method is applied to collect practitioner feedback. This paper describes the workshop structure, data collection and analysis, general observations and limitations of the study and implications for both educators and practitioners.

**Literature Review**

Design thinking was first used by Herbert Simon in his book called The Sciences of the Artificial (Simon, 1969) which became topic of interests by many design researchers in the field (Rowe, 1987). The Design Thinking Research Symposium was one of the initial explorations of design thinking as a new methodology for design research (Cross, Dorst, & Roozenburg, 1992). Today, “Design Thinking” is identified as an exciting paradigm for dealing with problems in many professions (Dorst, 2011) including information technology (Brooks, 2010; Lindberg, Meinel, & Wagner, 2011), engineering (Dym, Agogino, Ozgur, Frey, & Leifer, 2005), and business (Martin, 2009).

Roger Martin, in his Strategy & Leadership article (Martin, 2010) describes design thinking as a process of continuous business development using insights based on customer intimacy, which is often used in product, process and business model innovation. Tim Brown, CEO of IDEO – a renowned design consultancy firm, describes design thinking as applying methodologies and approaches of design to a broader set of issues and problems in business and society (Brown, 2008). The distinction and exchange between the problem and solution space clarifies the approach of design thinking (Newell & Simon, 1972), where the divergent and convergent thinking loops take place (Yilmaz & Daly, 2016). It’s the interchange between divergent exploration of problem and solution spaces while converging through using the processes of synthesizing and selecting the most promising outcomes (Lindberg et al., 2011). It seeks for exploring the problem space thoroughly, building intuitive understanding of the stakeholders, generating a diverse range of alternative solutions and conscious and justified decisions on the most promising solutions. It’s not a linear algorithm as it is more of an iterative cycles of both the problem and solutions spaces’ explorations.

While differences exist across design thinking definitions and the process, some common themes emerge. For example, Beckman and Barry described the design-led innovation process where they identified four main steps as observation, the user of frameworks for insights, the
development of ideas, and the selection of solutions (2007). Throughout this process, three key methods are cited the most for a design thinking approach (Brown, 2008; Lockwood, 2010): 1) needfinding, 2) brainstorming, and 3) prototyping. Needfinding includes a set of activities to determine the requirements and specifications of the solution space where the designer immerses himself in the user’s context to gain insights (Leonard & Rayport, 1997; Brown, 2009).

Brainstorming is a group process to promote alternative solutions through bouncing ideas among the team members (Sutton & Hargadon, 1996). Prototyping is the process by which preliminary models are built based on the novel ideas for assessing the quality of the idea and communicating the outcome with a broader audience to gather feedback (Hargadon & Sutton, 1997).

In summary, the three areas provide the basis for how a ‘design thinking’ approach can be applied in organizations. In addition to the methods, there are also toolkits (IDEO, 2013; Stanford, 2010) and frameworks (Hassi & Laakso, 2011; Liedtka & Ogilvie, 2011) proposed for design thinking. However, many of these are not empirically studies, and the one that are studied are usually examined under experimental conditions within academic settings. Little research has looked at their applications for fields outside of design industry and sought for the immediate perceptions of the managers to these methods.

**Research Methods**

The data analysed in this paper were collected as outcomes of a workshop developed for executives in the agriculture business, as part of an annual conference to provide a unique forum for assessing emerging trends and issues facing agribusiness today. The workshop was facilitated by the authors. Executives who attended the workshop were informed that their participation was voluntary and they could opt out of providing data throughout the session and/or the surveys.

The three specific challenges addressed in the workshop where the design thinking methods applied were:

1. addressing cross-functional team issues,
2. training employees to engage and push the boundaries of innovation, and
3. moving from a problem identification culture to a solutions-oriented culture

In order for the attendees to gather new ways of addressing these challenges, we designed a six-hour workshop with a focus on collaborative problem identification and solution. The workshop was structured around the principles of design thinking, and the participants walked through each phase of the process using six design thinking methods in order to understand and reframe the problems, in addition to solve and test the outcomes. This workshop used a selection of design thinking methods as they applied to business – namely, methods related to problem restructuring, ideating, and assessing the qualities of the ideas generated. The goal of the workshop was not to create an ultimate solution, but to build an understanding on the impact of design thinking approach in a way that would facilitate novel perspectives among individuals outside of the design field, as well as provide different insights to push each participant’s boundaries.
Research Questions

The questions we posed in this study were:
1. How do managers’ definitions for design thinking vary after a short workshop?
2. How do managers in a field outside of design perceive design thinking process and the methods?
3. How would the managers use the methods introduced to address a challenge within their organizations?

Participants

The study participants were executives from a diverse range of companies. They varied in their experience, age, and area of residence but all were employed at a company directly related to agriculture. In total, 28 professionals participated in our 6-hour workshop; of these, 21 attended the entire workshop and responded to our pre-post workshop surveys; thus, our sample is those 21 participants (N=21). Three of the participants were CEOs or presidents, four were vice presidents, four were directors or executive directors, and seven were managers in their companies. The other participants had titles such as an analyst or a consultant. Participant ages varied between 25 and 70 (M= 46, SD=13.35); five of the participants were female, and ten of the participants had master’s degrees, with the rest holding a bachelor’s degree. Fourteen of the participants have had over ten years of professional management experience.

Workshop Flow

The flow of the design thinking workshop is illustrated in Figure 1. We took Liedtka and Ogilvie’s (2011) design thinking process visualization and after many discussion, we chose methods that would be most relevant for this particular audience, across this process. Before the workshop session, participants were asked to complete an online survey, through which collected demographic information, educational background, current position in the company and responses to questions such as what is design thinking, how would design thinking be applicable in the context of management, and what are their expectations from the workshop.
During the workshop, participants were introduced to the definition of design thinking and a series of examples of how design thinking is implemented in different industries to solve known problems through an uncommon perspective. The design thinking process (Brown, 2008; Liedtka & Ogilvie, 2011) was explained in detail, with the steps to be taken. After the pre-survey and the introduction, participants were given 30 minutes for each activity and 15 minutes for discussion as a team. In total, 7 teams were formed. The teams were aligned around one table, working together during the entire session. An image of the room set up is seen in Figure 2.

After each method’s application, participants were handed out a reflection card asking them to respond to ‘How would you use this method to address a challenge within your organization?’ (Figure 3). Following the workshop, a post-workshop survey was distributed to the participants with questions specific to each method to help us understand their value and ease of application for the participants. Their suggestions were also sought to improve future workshops.
Design Thinking Methods applied during the workshop

Each method introduced a different mode of understanding what the true problem is and extracting creative solutions to common issues in the workplace, namely: cohesiveness within cross-functional teams, the challenge of employee motivation, the cultivation of a creative atmosphere, and organizational structure pitfalls that limit productivity. The workshop integrated collaborative discussion and feedback from participants. Each method used in the workshop is described briefly below. The methods were categorized into four stages of the design thinking process (Liedtka & Ogilvie, 2011): what is, what if, what wows and what works.

**WHAT IS - Method 1. Persona Creation:** Personas are ‘fictitious, specific, concrete representations of target users’ and used commonly in improving communication about the target users within the design team and other stakeholders. In order to create empathy with employees, the executives were provided a set of simple personas that were created by the workshop team based on the pre-defined problem areas (Cooper, 1999; Pruitt & Adlin, 2006). Each team was then asked to add details, such as, persona’s needs, wants, goals, and feelings, to these personas to reflect their own experiences with the employees in their organizations. Some of the prompting questions listed on these personas were: “What motivates this person?” and “What does this person value in life?” After a brief discussion among the team members, the teams created and explained why their persona had certain characteristics or feelings. Figure 4 shows examples of the persona sheets provided to the participants.
WHAT IS - Method 2. Journalistic Mapping: In the next step, participants were asked to systematically unpack the abstract thoughts that initially surround a problem statement. It is similar to a mind map where the graphical representations of ideas and aspects are aligned around a central theme. The main difference of this method that it’s based on Journalistic 6 questions that help journalists to find a focus, tell better stories and allow them to never stop questioning (Group, 2008; Huang, 2014). Participant teams were given a list of problem statements relevant to agriculture business and asked to choose one of the problem statements to address. For example, ‘How to motivate to take initiative within the organization? ‘How can we create an environment where feels comfortable failing?’ ‘How do we facilitate a company culture that drives innovation?’ Participants were also provided noun-verb combinations, such as, motivate-initiative, embrace-cross-functional teams. Using the correlating noun-verb combinations, participants explored their problem statements by asking who, what, where, why and how.

WHAT IF - Method 3. Wish Cards: Wish cards are used to engage imaginary and fictional thinking, encouraging participants to think divergently in proposing solutions (Michalko, 2006). Participants were encouraged to think imaginatively by filling out “I wish…” cards (Figure 5) that were provided in stacks. After ten minutes of individually recording many wishes as a response to the prompts provided in the journalistic mapping session, participants were told to place all the wish cards in the middle of the table, shuffle them, and randomly select a handful of cards. Their next task was to read each wish and propose a way to make that wish come true by answering the question on the back of the wish cards focusing on “How?” This approach allowed them to generate divergent, unconventional ideas first, and to assess and identify means to accomplish these next.
WHAT IF - Method 4. Negative Brainstorming: A second method chosen for the ideation phase was negative brainstorming. Negative brainstorming focuses on generating bad solutions to the problem, and then see how those could be transformed into good solutions (How, 2012). Participants were told to refer back to the problem statement they chose in the journalistic mapping session, such as ‘How to motivate to take initiative within the organization?’, and, as a team, asked to restate the problem three times so that the new problem statements were posing the same question in an opposite way. For example, ‘How could I possibly cause the problem?’ or ‘How could I possibly achieve the opposite effect?’ The second step in the process was to generate solutions to the reversed problem statement and reversing these solutions into solution ideas for the original problem statement (Tools, 1996). The purpose of this activity was to show how negative problem reframing could lead to more creative and innovative solutions and how thinking of a problem from a reversed point of view could broaden up the scope of the solutions.

WHAT WOWS - Method 5. Affinity Diagramming: The next method for the workshop was the affinity diagrams to organize the generated solutions according to their natural relationships. Affinity diagrams are a popular “six Sigma” tool for organizing ideas into categories based on their underlying similarity, and they help to identify patterns and establish related groups that exist in qualitative datasets (Pyzdek, 2003; Shafer, Smith, & J.C., 2005). At the workshop, it is used to review and categorize the ideas generated during the wish cards session to be sorted into clusters. This exercise revealed patterns of thinking and allowed participants to visualize the common paths of thinking that were present in the group.

WHAT WORKS - Method 6. Roleplaying: Roleplaying takes the individuals out of their chairs and into the physical and social space where they would explore the solutions at a very early stage (Svanæs & Seland, 2004). It is commonly used as a way for designer and users to have a dialogue about design ideas (Brandt & Grunnet, 2000). Within each team, participants were split into employers and employees. Drawing from previous solutions and conversations they had, they created a scenario and acted as their character in order to test the validity of their ideas.

Discussion
The results of our study are presented by each session, beginning with personas and proceeding through each of the seven design thinking methods. In each case, we start with observations about the practitioners’ performance in the appropriate session, and then move to their perceptions about its value, ease of use, and application. Following these discussions, we present a summary section in which performance and perception data across the seven methods are analysed.
**Design Thinking definitions provided by participants**

As part of the pre-survey, participants were asked to respond to whether they have heard of the term ‘design thinking’, and if so, whether they could define it. Three participants out of 21 said that they have heard about the term; however, their definitions were rather simple statements mostly focusing on different ways of approaching to problem solving. Below are the three definitions:

- **P3:** “Alter our way of thinking”
- **P15:** “Different structures to use to develop solutions”
- **P16:** “Utilizing different creative thinking strategies to address business issues”

When the same question was posed at the end of the workshop, as part of the post-survey, all 21 participants were able to respond to what design thinking was. Their responses were characterized in three categories. First category was about the thinking process, second one focused on the systematic approach, and the third one was about using the tools in an optimized manner. Examples from each category are provided in Table 1.

**Table 1. Examples of Design Thinking definitions provided by the participants**

<table>
<thead>
<tr>
<th>What is Design Thinking?</th>
<th>Example Definitions</th>
</tr>
</thead>
</table>
| Emphasis on process      | P8: “Define the problem, analyze the pros and cons by asking good questions practice/test a solution then implement this solution (execute)”  
P9: “Digging deeper into a core assumption by understanding more about people and then coming at the assumption through various angles”  
P14: “Process to identify what works by placing self in shoes of others and working through concepts/ideas from that point of view” |
| Emphasis on systematic approach | P3: “A different way of thinking that leads solutions/answers that aren't the most obvious - forces us to frame the problem in a systematic way”  
P26: “Discovery, iteration, trial, and movement forward” |
| Emphasis on the use of tools | P4: “Using deliberate and purposeful tools to drive the best and most innovative outcome of a team”  
P6: “An approach to solve multidimensional problems through creative methods” |

The definitions provided by the participants demonstrated that they saw design thinking as a thought process requiring a systematic way to understand the real problem and through going through series of steps, offering unique solutions. Another important part of their proposed definitions was the focus on the user which is critical for design thinking. They also seemed to understand the purpose of the methods introduced and how they can be used to investigate complex problems regardless of the domain they are coming from.

On another question, when participants were asked how they thought design thinking would
influence their organizations, their responses varied across two topics: stimulating creativity throughout the entire organization and aiding in improved competency and efficiency. Based on their responses, it is clear that they were able to elaborate on how design thinking could bring an additional edge to their competency and make their processes more efficient. They also commented on its potential influence on long term solutions and building an innovative culture within the organizations. A set of example responses are provided in Table 2.

Table 2. Example responses to the question on the potential influence of design thinking on participants’ organizations

<table>
<thead>
<tr>
<th>What can be the influence of Design Thinking on your organization?</th>
<th>Example Responses</th>
</tr>
</thead>
</table>
| Emphasis on stimulating creative thinking | P3: “Involves a level of critical/innovative thinking that goes beyond the surface level. Allow to find real long term solutions”  
P20: “Can influence us to be more creative in how we solve issues and problems”  
P21: “Helping people think outside box - no dummies, no bad ideas” |
| Emphasis on improved competency and efficiency | P1: “Helps you get to the root cause of issues in a more effective way”  
P11: “Companies need to constantly be working ahead and finding ways to differentiate itself”  
P16: “Gives me a systematic approach to find viable solutions faster” |

Participants’ Perceptions of the Design Thinking Methods introduced

The reflection cards gathered after each method was introduced and applied provided another set of information about participants’ perceptions of the potential impact of design thinking into their individual organizations. We describe the patterns of the responses provided by the participants for each method and discuss their implementation for industry, in general.

Design Thinking Method 1. Persona Creation

Most participants seemed to understand the application of personas as part of the design thinking process and were able to explain how they could use it to address a challenge within an organization. Five of them found this method being the most immediately applicable method for their organizations where Participant 5 said that they could benefit from taking his own personal ideas and opinions out of the situation and truly find solutions that would fix a problem for the people it impacts. The responses, in general, focused on how personas could be used for changing one’s perspective on the problem and seeking improvements for existing solutions.

Below are some of the example responses.

P3: “Requires you to seek to understand the employee or customer to better tailor solutions”

P9: “Understand the why's behind someone's action; Better feel for where that person is in life; what the person sees as relevant”
P13: “To seek an understanding outside of my own thoughts and opinions. It would help to remove myself and think in terms of someone else”
P28: “Understand the value system of an individual - what makes them talk and how they think”

**Design Thinking Method 2. Journalistic Mapping**
Journalistic mapping rated as the most applicable method to participants’ individual organizations (8 out of 21). The responses were rather articulate and detailed and focused on revealing the root of the problem in order for a thorough understanding of the problem given. Below are some of the example responses:

P3: “Drives problem solving to the root. Most negative characteristics of our persona are symptoms of a larger root problem. Mapping forces us to ask the right questions to get the root of the issue”
P20: “Helps determine what questions we may not know the answer to and need to be asked => furthers relationship development and understanding of issue”
P24: “Writing down the verb: noun combinations that solidifies the essence of the problem as a means to keep a problem solving team focused on the core issue”

**Design Thinking Method 3. Wish Cards**
Wish cards were also rated highly for their immediate application in organizations (6 out of 21). The responses suggested that the participants saw value of using them in bringing people together by allowing freedom to explore while creating spontaneity across team members. Since the method doesn’t ask for verbal contribution from the team members, participants saw this a positive approach in getting open-minded responses where nobody is judged or assessed.

P4: “It is a great way to get individual participation without having to call out a person individually”
P9: “Be open minded when thinking of solutions; solve the problem or at least try; Dream big; don’t throw it out; consider it”
P27: “Very oral method which encourages teamwork & spontaneity - a process that "forces" creative in a retained and fair way into problem solving process”

**Design Thinking Method 4. Negative Brainstorming**
Participants found negative brainstorming as another effective method for promoting novel solutions. Reversing the problem into a negative statement allowed them to cover all levels of possible solutions. They acknowledged the importance of negative thinking to generate unique solutions that may not be obvious otherwise.

P2: “Don't ignore the negative. There is a lot to be learned from what is not working... do the opposite and you can make it work”
P14: “Intend to use this when employees say something "can't be done" - list reasons why it can't and reverse those to ‘how they can’”
P20: “Would help get around ‘road blocks’ that may have people stuck in decision making process; May reveal a solution that is ‘outside the box’”
**Design Thinking Method 5. Affinity Diagramming**

Affinity diagramming was found useful for evaluating the importance and relevance of the different solutions to the problem at hand and prioritizing the goals. Participants also found this method helpful for its contribution to decision making and creating a consensus across the team member to agree on the chosen concept.

- **P5:** “We often have several different initiatives at a time. This would help us prioritize initiatives”
- **P6:** “Could be useful in our strategic planning each year to prioritize new ideas or allocation of limited capital”
- **P20:** “Focus resources & time on the higher scoring/higher benefit component ideas or solutions”

**Design Thinking Method 6. Roleplaying**

Roleplaying was rated as the most challenging method (11 out of 21) as it required participants to get out of their comfort zones and act as other people without a written script. Participants who found this method effective stated that it would be useful in training employees for new positions as part of employee orientation programs or tough conversations, such as firing an individual. Seeing both sides of the conversation through empathizing with others was acknowledged often.

- **P9:** “See yourself in the situation; Go through possible scenarios; See both sides”
- **P13:** “This is a great context to use for solving uncomfortable situations within a management team or organization”
- **P28:** “Role playing would be helpful in teaching people about how others respond. I would use it when trying to impress how various people and value systems show up differently in the work place”

Our results revealed strengths and weaknesses of each of the design thinking method introduced. All of the participants acknowledged the importance of design thinking as a new thinking process and its potential value for their organizations. Adopting this new approach seemed to be easy for many managers as they were comfortable with elaborating how they could integrate these methods to solve some of the problems in their existing settings. While there were some differences in precise definitions, they were mostly able to integrate some of the design thinking terminology when they were asked to describe what design thinking was.

Out of the six methods introduced, participants found journalistic mapping and wish cards to be the most applicable methods as one was asking for deep dive on the problem space with WWWWH questions and the other was opening the solution space without any limitations or judgements. On the other hand, roleplaying was seen as a challenging method for a business context since it required participants to move out of their comfort zones and act as different people after building empathy. Overall, the workshop was well-received and the goals of the session were achieved. We argue that the adaptation of methods commonly used in design context to business context needs extra effort on the researchers and educators as the purposes of using such methods often vary. For example, instead of introducing personas to the group and letting them figure out how to apply, we prepared simple personas that the managers could relate to immediately and add details to reflect their potential employees. On another example, we provided a set of questions for them to choose from as an initiation step.
for journalistic mapping which allowed the teams to focus on a related business problem and explore what additional problems could be involved. While this additional effort can be time consuming, it seemed to facilitate in-depth conversations on building empathy, fully exploring the problem and solution spaces, as well as assessing the outcomes.

The small sample size for this study limits our ability to generalize; however, such studies, especially with practitioners, are not intended to generalize but instead offer important insights about the ways the design thinking methods could be modified to better suit the audience. Due to the limited timeline for the entire workshop, participants were only given thirty minutes to practice with the methods. Our future work will include additional studies with both practitioners and students on different design thinking methods.

Conclusions

In this paper, we have discussed the perceptions of managers on design thinking approach and how they recognize the value it could bring to different business settings. We have also discussed the need for more empirical research on the adoption of these methods by management discourse and argued that further research is needed that would help in making the transition from one domain to another. Next steps would be revisions of the supporting materials for each design thinking method based on the feedback from the participants in this study, additional studies with larger samples, designing and developing supporting materials for different academic contexts, and dissemination of these methods to general practitioners based on practice in the field.

**Author Biography**

**Seda McKilligan**
Dr. McKilligan is an Associate Professor of Industrial Design at Iowa State University. She teaches design studios and lecture courses on developing creativity and research skills. Her current research focuses on identifying impacts of different factors on ideation of designers and engineers, developing instructional materials for design ideation, and foundations of innovation. She often conducts workshops on design thinking to a diverse range of groups including student and professional engineers and faculty member from different universities. She received her PhD degree in Design Science in 2010 from University of Michigan. She is also a faculty in Human Computer Interaction Graduate Program and the ISU Site co-director for Center for e-Design.

**Tejas Dhadphale**
Dr. Dhadphale is an Assistant Professor in Industrial Design at Iowa State University. He received his doctoral degree in Industrial Design from the Herberger Institute for Design and the Arts at Arizona State University. His research critically examines the role of design research in design education and practice. He has taught classes in design research methods, design thinking, multidisciplinary innovation, and human-centred design. Trained as a design researcher, he is passionate about developing theoretical and methodological framework for designers and researchers to integrate cultural aspects into the new product development process.

**David Ringholz**
David Ringholz is an Associate Professor and Department Chair of Industrial Design at Iowa State University. His research interests are on auditory branding, electronics prototyping, instructional technology, design for diversity, small-scale manufacture and furniture and lighting.
Developing DIVE, a design-led futures technique for SMEs

Abstract

Futures techniques have long been used in large enterprises as designerly means to explore the future and guide innovation. In the automotive industry, for instance, the development of concept cars is a technique which has repeatedly proven its value. However, while big companies have broadly embraced futures techniques, small- and medium-sized enterprises (SMEs) have lagged behind in applying them, largely because they are too resource-intensive and poorly suited to the SMEs’ needs and idiosyncrasies. To address this issue, we developed DIVE: Design, Innovation, Vision, and Exploration, a design-led futures technique for SMEs. Its development began with an inquiry into concept cars in the automotive industry and concept products and services in other industries. We then combined the insights derived from these design practices with elements of the existing techniques of critical design and design fiction into the creation of DIVE’s preliminary first version, which was then applied and evaluated in two iterations with SMEs, resulting in DIVE’s alpha version. After both iterations in context, it seems that DIVE suits the SMEs because of its compact and inexpensive activities which emphasize making and storytelling. Although the results of these activities might be less flashy than concept cars, these simple prototypes and videos help SMEs internalize and share a clear image of a preferable future, commonly known as vision. Developing DIVE thus helped us explore how design can support SMEs in envisioning the future in the context of innovation.

Keywords: Design futures; concept cars; futures techniques; speculative futures; SMEs

The majority of the globe’s productive sector consists of small- and medium-sized enterprises (SMEs), each employing fewer than 250 people and with an annual turnover below EUR 50 million. SMEs at times, like any other business, need to re-invent themselves, not only to survive in the market but also to drive society towards a sustainable future, where communities meet their demands, considering the depletion of natural resources and without compromising the needs of the next generations (The World Commission on Environment and Development, 1987). To address this urgency, SMEs could turn to applying so-called futures techniques, such as scenario thinking, which according to van der Duin (2007) are commonly used by managers in corporations to create a company’s long-term innovation strategy. However, while the use of such techniques appears to improve SMEs innovation performance (Augustine, Bhasi, & Madhu, 2012), many cannot apply them (Stonehouse & Pemberton, 2002;
K. O. Vishnevskiy & Egorova, 2015) because they are too complex, too resource-intensive and too far-fetched (van der Duin, 2007). Thus, according to Paliokaité (2010; 2013; 2015), Phillips (2013), and Vishnevskiy and Egorova (2015), SMEs demand simplified futures techniques tailored to their specific characteristics.

This paper describes the development of the first version of DIVE: Design, Innovation, Vision, and Exploration, a design-led futures technique tailored to SMEs. DIVE consolidates the learnings from our previous studies on concept cars, an established design practice used by large automakers to explore and communicate the future, which was adapted to fit the needs and limitations of SMEs in any industry. We first discuss how futures techniques can support enterprises’ innovation, paying specific attention to their potential value for SMEs and the challenges developing futures techniques present for SMEs. Next, we explain DIVE’s development process, followed by a description of its components. During its development, DIVE was evaluated with SMEs in two studies, which are described to illustrate how the characteristics of these enterprises have influenced the development of DIVE.

The paper makes two contributions for designers and design researchers interested in the confluence of futures studies with design for SMEs. First, it addresses the value of design and design-led techniques to support smaller firms in the front-end of innovation. Second, it provides insights into the common challenges and opportunities of developing design techniques for this particular context and these unique enterprises.

**Futures techniques**

Futures techniques—the variety of ways to think, map, and influence the future (Hines, 2016)—can be classified into two categories: management-led and design-led (Mejia, Pasman, & Stappers, 2016). Management-led futures techniques pursue a systematic, analytical and verbal process, which usually ends in rational outcomes targeted at specialized audiences. Typical examples of these techniques are technology roadmapping, scenario thinking, and trend analysis. Although these techniques are valuable, their processes and results have several limitations. Their processes favor abstraction (Candy & Dunagan, 2016; Phillips, 2013) and thus lack contact with real situations, and they are resource intensive and time consuming (Coates, 2003). Furthermore, their outcomes are normally high-level scenarios which lack a sense of the human-scale (Candy & Dunagan, 2016). Therefore, management-led futures techniques tend to fall short in informing other people involved in innovation, thereby making implementation and diffusion more difficult.

By contrast, design-led futures techniques “engage people more viscerally in futures conversations” (Candy & Dunagan, 2016), bringing futures techniques “out of the abstraction and into the experience; into the body” (Candy, 2010). These futures techniques do not follow a cognitive reasoning process but instead use the designerly way of knowing, which translates abstract questions into concrete objects (Cross, 1982), to creatively explore speculative futures. This approach uses making activities, such as prototyping, “as vehicles for […] exploring, expressing and testing hypotheses about future ways of living” (Sanders & Stappers, 2014). Therefore, while management-led futures techniques produce mostly highly complicated and abstract outcomes, the results of design-led futures techniques are
fictional artefacts which are more accessible and engaging to the general public.

But what about the SMEs?

While futures techniques are useful for larger enterprises, their characteristics limit their use for SMEs. In working with SMEs over the last fifteen years, we have come to realize that although these enterprises are concerned about the future and want to leave a legacy to their families and communities, they rarely think about the future in more detail. The reason may be that they get trapped in a vicious circle of a lack of resources and the urgency of the present. SMEs spend much of their resources on operational activities, and are left with no means to explore the future as extensively as large corporations get to do (Holmes & Ferriill, 2005; Hewitt-Dundas, 2006; van der Duin, 2007; Augustine et al., 2012; K. Vishnevskiy, Karasev, & Meissner, 2015). This lack of resources means they cannot create a department dedicated to futures and innovation with specialized researchers with the appropriate skills to study the future and enough information to analyze medium-term and long-term trends (Christofol, Delamarre, & Samier, 2009). The urgency of the present exacerbates this lack of resources, forcing SMEs to act immediately, putting off any behavior that focuses on the future, “such as planning and delaying gratification” (House, Hanges, Javidan, Dorfman, & Gupta, 2004). For many SMEs, trapped in this vicious circle, “there will always be an excuse not to look beyond the here and now” (van der Duin, 2007).

As mentioned above, large enterprises have another way to think about the future, the design way, but this is also not the case for SMEs. While some design researchers (Selek, 2009; Yström & Karlsson, 2010; Mortati & Cruickshank, 2011; Rodriguez Donaire & García-Almiñana, 2012; De Lille, 2014) have examined issues related to the role of designers working in, for, or with SMEs, little is known about how design can support SMEs in exploring the future. Research by Delamarre et al. (2005) and Christofol et al. (2009), however, suggests that “concept products used in major companies are pertinent for providing [...] innovation in SMEs”. These inquiries studied the making of two concept products by a medium-sized company, which collected a considerable number of trends and ideas of new products, resulting in twenty-nine strategic road maps and two patent applications. In the latter study, they suggest that making concept products brings together investigations in diverse fields and fosters the development of new behaviors, such as curiosity and lateral thinking, thus increasing the SMEs’ innovation performance (in this case by 30%). These claims were also hypothesized by Borja de Mozota (2002), who states that the making of a concept product is an effective tool for smaller enterprises to view the future and incite reactions from other departments.

Considering the insights on futures techniques in corporations and the characteristics of SMEs described above, vision concepts appears to be a promising way to sketch and anticipate the future of smaller players in different branches of the industry. However, due to the limitations of this context, the technique will need to be adapted. The question is then: can SMEs derive the same benefits from applying vision concepts?

The development of DIVE

In a previous study (Mejia, Hultink, et al., 2016), we found that concept cars are made using a
hands-on process, which uses visual synthesis, prototyping, and storytelling, to explore and communicate the future. As Figure 1 shows, the basis of this process is a creative brief, which includes a design challenge and a time frame. Following this brief, the making activities start with an analysis of future context factors to define a vision of a preferable future in alignment with corporate values and strategic direction. Based on this vision, designers make sketches and rough prototypes, at different scales and resolutions, to create, develop, test, select, and share ideas with people within the company. When they share these ideas, whether a new technology, style, or interaction, designers create short stories to give them context. When the final idea is selected, they make a refined prototype and a video, to visualize the concept car, and its interaction with users within its context. At the end of these activities, the company shares the physical and narrative manifestations to allow many parties involved in change, both inside and outside the enterprise (Mejia, Hultink, et al., 2016), to experience the concept car as true to reality as possible, to spark discussions about its future. These conversations take place through workshops and exhibitions at three different context levels: team, in-company, and public.

![Figure 1. Flowchart with the concept cars’ making and sharing activities (Mejia et al., 2015).](image)

The result of this design-led technique is a concept car: an ‘experimental artifact’ (Styhre, Backman, & Börjesson, 2005) of the future, unrestricted by constraints imposed by the present conditions, such as production capabilities and market regulations. Figure 2 displays an example of a concept car shown for public viewing at a motor show.
At the end of this study, we identified that this design practice is not for the exclusive use of automakers, as different corporations in other industries also make and share concept cars, products, and services. Some corporations call such artifacts ‘concept cars’ even though they don’t produce cars, such as Intel and Microsoft, while others such as Ikea, Philips, and Electrolux call them ‘concept products’. To avoid confusions, we will refer to concept cars, products, and services from now on as vision concepts, following the notion introduced by Keinonen and Takala (2006). Vision concepts materialize the company’s image of the future through an artifact and a story that can be experienced by different people, putting this vision into action (Mejia, Pasman, et al., 2016), and supporting “the company’s strategic decision-making beyond the range of product development” (Keinonen & Takala, 2006). Large enterprises make vision concepts as a design-led futures technique to gain insight into the future and thus assertively make decisions in the present to guide their innovation (Mejia et al., 2015).

However, making vision concepts is a time-consuming and expensive activity, requiring a costly team of highly skilled professionals, including designers, engineers, and brand and communication experts. Typically, an automotive manufacturer employs a team of six professionals for a period of approximately eight months to develop a concept car, with a final investment of around one million Euros (Mejia, Hultink, et al., 2016).

To downscale the making and sharing activities described above, we turned to two other design-led futures techniques which come from academia and are applied in smaller-scale projects: critical design and design fiction. According to its creators, Dunne and Raby (2013), critical design “uses speculative design proposals to challenge narrow assumptions, preconceptions, and givens about the role products play in everyday life”. Design fiction is a technique to develop “micro future studies that pay particular attention to the everyday life and the standard objects or services that might fill possible futures” (Girardin, 2015). Both techniques use the materiality and language of design to prototype elements of a believable future (Candy & Dunagan, 2016).

There are three things that make these two design-led futures techniques particularly interesting: (i) they use fewer resources, much less money and time than techniques used by large
corporations; (ii) they effectively use rough prototypes and simple videos to trigger reactions and spark conversations; and (iii) they create more radical concepts, which challenge the present situation and propose an extreme change for a broad range of topics, from social to environmental, including technological issues.

First iteration: The Alchemist Club 2025 for Marlioū

To define the characteristics of DIVE, we formulated a value proposition, which clarifies the way in which the value—or benefit—will be delivered and experienced. DIVE’s value proposition was stated as: “a rapid, inexpensive, and practical design-led technique to support designers and business people who run SMEs in exploring and communicating speculative futures to boost their innovation capabilities.”

In view of the value proposition and the insights from critical design, design fiction, and concept cars—including the making and sharing activities described in Figure 1—, we collected and defined initial ideas in an ad-hoc iteration with Cosméticos Marlioū Paris; a Colombian medium-sized enterprise focused on hair care products. In this iteration, the first author acted as the designer.

To understand the company and thus define the creative brief of this exploration, the first author used a tool he created: Strategic PES. This tool deconstructs SMEs to identify their values and know-how, products and services, facilities and stakeholders, and end-users, through a simple workshop (Mejia & Parra, 2014). It builds on the similarity correspondence between a company and a living being: a fish1, whose goal is to survive and reproduce in a body of water. Following the analogy, the fish embodies the enterprise; the river, lake, or ocean symbolizes the context in which the organization delivers value; and the adaptation to the context’s change implies the innovation. Only fishes that properly adapt to a changing context can survive. Since 2011, the first author has applied this tool in twenty-five large projects with SMEs, and around eighty intensive workshops with more than four-thousand business people in Colombia, Suriname, and Peru. It proved to be effective in disentangle the business people from the company, facilitating a more objective diagnosis of the firm’s condition without any hard feelings. Furthermore, participants can see the company as a whole, understand its complexity and recognize the relationships among the company, external stakeholders, and the context, as well as the internal relations (Mejia & Parra, 2014). In this iteration, the Strategic PES revealed that “Marlioū is a two-headed trout, living in a peaceful pond”. Through its life of permanent service to the community, the trout is changing, and sprouted a second head; as the family enterprise is handing down the business to the third generation, the company seems to move in two opposite directions at the same time. One head, the incoming manager, wants to move to an unexplored small pond, a high-income market where the company can use information technologies; the other head, the outgoing director, is focused on the current pond, where the fish is already well known by many low-income users. Marlioū needs a new vision of a desirable future, genuinely informed by its beliefs, that blends the desires of the relevant heads, the family members. After analyzing products trends and

1 In Latin America PES is pronounced as pez, which means ‘fish’ in Spanish.
users’ expectations, the first author defined a vision for 2025: “Marlioü wants to reinforce its presence in the low-income market by offering a personalized care service via a network of beauty consultants, who are fully supported by information technology, helping them identify users’ needs.” With that vision, he sketched the service offered by the consultants and the equipment they needed. With these sketches, the first author made rough cardboard prototypes of various initial ideas of products and mobile apps and then tested these in a role play with two designers (see Figure 3).

This exploration resulted in a vision concept: *The Alchemist Club 2025* shown in Figure 4. It is a network of beauty consultants assisted by a kit of hair products; an input device which interact with tablets and cell phones to measure, compare, and experiment with the hair products; and a do-it-yourself apron. All these elements are supported by a mobile app which trains the beauty consultants and collects insights from the clients. Finally, he developed a sequence of screenshots of a Twitter account to share the vision concept. The sequence of tweets presents the story of a fictional beauty consultant, part of The Alchemist Club, in 2025.

In this iteration, the first author examined how to align the conflicting visions of the incoming and outgoing managers, and the company values. The vision he came up with shows how the company can use information technology to improve client contact. It also identifies how the company can engage with beauty consultants to reinforce Marlioü’ presence in low-income markets.
This iteration tested, at an early stage of the development, the essential activities (in view of those shown in Figure 1) to make the vision concept for the SME, including the definition of the primary resources needed: forty hours of a senior designer.

The activities were sufficient to make the vision concept with few resources. He incorporated a company evaluation, prior to the future context analysis. In this activity, the first author was guided by a powerful analogy that, with little time, brought plentiful insights into the company. However, a visual aid is needed to reinforce this analogy. To formulate a vision, a simplified STEEP analysis\(^2\) was sufficient. After that, again with little time, the first author tested the initial idea using rough prototypes in a role play. This leap out of the abstraction of the company’s diagnosis and the context factors into the vision concept, at the earliest phase of the process, was tremendously useful as it gives us time to reflect on the experimental artifacts and the service, the vision concept, and therefore, collect more ideas about its context, the future. However, we needed a closing meeting where the enterprise gets to implement the vision concept, and the recommendations emerge in consensus with the company representatives, instead of just from the designers.

At a content level, this iteration gave evidence that DIVE starts by analyzing the company values and continues by identifying the values of the human beings, who are or will be related to the enterprise. The technique ends with a vision concept, an artifact that explores the

\(^2\) social, technological, economic, environmental, and political
desirable interactions, deeply informed by those values, between the company and these people in the speculative future.

**DIVE: Design, Innovation, Vision, and Exploration**

Based on the lessons from this iteration, we then developed the first version of DIVE (see Figure 5) by extending the analogy of Strategic PES. DIVE is a design-led futures technique that assists designers in making and sharing vision concepts for SMEs. It is developed to be used by a team which includes up to three external designers, as process owners, and three company representatives, as problem owners. The former should have expertise in design researcher and communication, and the latter, as Sanders and Stappers (2012) say, “are the experts of their own experience”. In this version of the technique, the making and sharing of the vision concept takes forty hours of the designers’ time and ten hours of the company representatives’ time and a small budget for visuals and prototypes.

The technique consists of a quick dive into the depths of speculative futures and a swim back to the world as it is. During this journey, designers act as instructors and the company representatives as scuba divers. Initially, underwater, the company is seen as a fish that swims in calm or troubled waters. Instructors then accompany the divers in envisioning future waters and defining a vision. Using this vision as an inspiration, instructors and divers draw, make prototypes, and create stories to set up the vision concept, resulting in a rough prototype and a video. Finally, on land, the instructors use these artefacts to spark a conversation among several people about the future of the fish, shining a light on the decision-making in the present. DIVE follows a path along *five activities*, shown in Figure 5: (i) Understanding the present, (ii) Approaching the future, (iii) Exploring the future, (iv) Communicating the future, and (v) Looking back into the future.
As part of the **Activity 1 Understanding the present**, the designers apply the Strategic PES (shown in Figure 6) with the company representatives, to set a *domain* and a *time frame*. According to Hekkert and van Dijk (2011), the domain delimits the focus area of the process in which designers aim to contribute, “acting as a map that guides [the] exploration of the context and the factors to be taken into account. [It is] (preferably) a particular area in life.” Moreover, the time frame is an interval of time which moves from the world as it is to the speculative future, to help companies map change when they think about the future (Mejia, Pasman, et al., 2016).
According to Mejia, Jimenez, and Chavarria (2014), the fish, which represents the SME, is divided into four parts: its head describes the company’s know-how; the tail shows the users as a rudder that steers the company; the back displays the company’s infrastructure; and the belly plots the products and services.

In **Activity 2 Approaching the future**, the designers conduct desk research and field work to collect context factors (see Figure 7). With this picture of the future, they cluster these factors with the company representatives to define a vision, which captures what the vision concept should do and be before it is made. The vision consists of a statement describing what the designers want to offer people within the domain, including a definition of the interaction qualities (Hekkert & van Dijk, 2011).
Following the vision, in Activity 3 Exploring the future, the designers imagine, experience, test, select, transform, develop, and complete early ideas by making different prototypes: sketches, diagrams, and mockups (Sanders & Stappers, 2014). By the end of this activity, they will have a collection of information that describes the vision concept: a concept product, service, or product-service system.

In Activity 4 Communicating the future, the designers make a rough prototype and create visuals and a narrative to share the vision concept. The last two elements support the prototype, placing the vision concept in an image of the future, complete with people, context, and their relationships. This support is important because, as Stappers (2013) argues, rough prototypes are physical manifestations of ideas or concepts that only give the overall idea, to evoke discussion and reflection.

Finally, in Activity 5 Looking back into the future, the designers facilitate a conversation with the company representatives and other stakeholders to map the company’s future. The designers use the vision concept, embodied in the prototype, the visuals, and the narrative, to help participants express their thoughts, feelings, and ideas about the company’s future. Along the conversation, the designers make a road map with strategic recommendations for the near and speculative future of the SME.

The activities were described in a booklet together with the two canvases shown in Figure 6 and 7, which support the designers in documenting the first two activities.

Second iteration: Continental Energy 2030 for Continental Boilers

The first author, in collaboration with two senior designers, ran this second iteration with Continental Boilers, a small-sized family enterprise focused on the manufacture and delivery of steam boilers, hot water systems, and heat exchangers.

Through the Strategic PES, we found that “Continental Boilers is a salmon with small fins – products with minimal turnover, long life-cycle, and inexpensive maintenance– and it is swimming against the current.” To survive in the river, the salmon either needs to grow the muscles of its fins or find an alternative way to swim, such as by introducing new products or another business model. After a STEEP analysis, in which several context factors were organized in a 2X2 matrix, a vision emerged: “Continental Boilers wishes to provide steam and hot water to factories within industrial parks through a service that follows the client’s needs, being in the forefront of the environmental regulations.” After several iterations, which included sketches of new services and products, we created the vision concept: Continental Energy 2030, a service that includes the selling of steam and hot water and the renting of portable boilers and heat exchangers. To support this service, the company will offer the client a mobile app to control its consumption and receive technical support. Following this activity, we produced a simple video of a fictional client, an industrial laundry, in need of steam and hot water for its washers and dryers that help reduce its energy consumption. Through the video (see Figure 8), we introduce the main features of the 2030 service.
We arranged a workshop with three company representatives: the general manager and the directors of innovation, and marketing and sales (see Figure 9). We used the video to stimulate a conversation about the Continental Boilers’ desirable futures. Based on this conversation, we formulated a series of recommendations setting a track between the present and the future, explored by the vision concept.

This exercise explored how Continental Boilers might increase their business with a solution that is aligned with its values on sustainable development. The vision concept describes a transition from a product-driven business to a service-oriented model and portrays the potential allies that can help this transition.

This iteration was useful to consolidate the definitive activities and the technique’s resources: forty hours of the senior designers’ time and ten hours of the company representatives’ time. Although this iteration needed an extra activity – a closing meeting – and more resources than the previous one, the consolidated activities were sufficient to make and share the vision concept within the limitations of an SME.
Both the initial analysis and making the video took longer than expected, but the video proved essential in sharing the vision concept and its context to effectively stimulate the conversation with the company representatives in the closing meeting.

According to the designers, standards by which they could judge the quality of the outcomes are needed; they additionally suggested templates to document the process. Considering that not all designers have the same skills facilitating workshops, they also proposed incorporating recommendations on how to deal with the company representatives, who tend to talk mostly about the present instead of the future, especially during the closing meeting.

The company representatives were positively surprised by the way the designers incorporated the company values within the vision concept, and the insights delivered by this exercise that they described as “design for strategic innovation.” They considered that DIVE is beneficial to identify short-term challenges; some of them related to the product, such as the question phrased by the general manager: “how do our boilers adapt to different types of energy?”; and others to the general business strategy, such as the value proposition formulated by the director of marketing and sales: “I don’t sell boilers, I sell energy solutions.” Having identified these challenges, company representatives put them on the agenda, stimulating their feeling of urgency motivated by the way the ‘world as it is’ is changing. They also identified potential alliances and allies that help the enterprise face this change. The general manager summarized the DIVE experience as the “first moment, in a long time, that [they] had the chance to look at the future.” According to him, they are “so involved in the daily life –[they] have been doing the same for 48 years– that it’s difficult to think ahead”. However, he identified that “it’s hard to manage change within the enterprise’s culture, in particular when it involves family members’ interests. But this exercise was useful to see the company in the light of international trends and understand their potential effect on the business.” He also mentioned that “it was nice to see a concrete example of our environmental values in practice and guiding our future actions.”

**Conclusions and further research**

Throughout the development of DIVE, in particular during both iterations in context, it became clear that design can be a powerful instrument to get representatives of SMEs thinking, talking, and acting about their company’s future. DIVE seems to be well suited to the preferences and idiosyncrasies of this particular type of enterprise. It is compact, both in terms of time and money; it has a hands-on character, as it involves making prototypes and videos; and it emphasizes concrete outcomes on a human-scale rather than abstract strategies. As such, designers and design researchers who are developing techniques for SMEs could benefit from the process described in this paper.

By turning concepts into simple physical prototypes or videos, DIVE makes it easier for participants to understand and adopt a future vision that fulfils their expectations. While these vision concepts might be far less showy than high-end concept cars, their down-to-earth qualities and unfinished nature make them much more accessible for discussion and reflection. Even though the making of these prototypes and videos takes up a considerable part of the available resources, its application is essential and should therefore always be included in a
design-led futures technique.

While DIVE certainly shares elements with other techniques that apply co-creation principles, its novelty is in its visionary character and the value it puts on the making of a realistic vision concept. The experiences from both iterations indicate that this forward-thinking exercise provided the participants with some new horizons as well as specific directions for their company’s future. More development is needed, however, to tailor these aspects further. Finally, DIVE has so far been evaluated in controlled settings, with the main author acting as the leading designer and facilitator. The next challenge will, therefore, be to put DIVE out in the field, to be able to evaluate how it will stand up on its own. We hope to report on the results of such an evaluation in due time.

Applying Design Thinking for Business Model Innovation for a Nonprofit Organization – Case Study: Art á la Carte

Alison Miyauchi, Watkins College of Art, Nashville, Tennessee, USA, amiyauchi@watkins.edu
Scott Cressman, Alberta College of Art and Design, Calgary, Alberta, Canada, Scott.cressman@acad.ca

Abstract

The challenges facing many small nonprofit organizations are increasing at a greater rate than the internal capacities of many within this sector are able to address effectively. This situation has small nonprofits questioning their sustainability and ability to deliver their services in the long term. Often these small nonprofit organizations are working within a business model and communications paradigm that has remained unchanged for decades and one which is proving no longer effective in attracting awareness, engagement, and support. Many of these organizations are facing a critical failure requiring significant business model innovation to achieve both their short-, mid- and long-term goals. Design thinking is an avenue for nonprofits to achieve business model innovation by developing new, unique concepts supporting an organization’s viability and the processes for bringing those concepts to fruition. This case study outlines the design thinking process applied to business model innovation for a small, 22-year old, nonprofit approaching critical business failure.

Keywords: Design Thinking, Business Model Innovation, Nonprofit Sector, Patient Services, Art Therapy

The challenges facing many small nonprofit organizations are increasing at a greater rate than the internal capacities of many within this sector are able to address effectively. This situation has small nonprofits questioning their sustainability and ability to deliver their services in the long term. Often these small nonprofit organizations are working within a business model and communications paradigm that has remained unchanged for decades and one which is proving no longer effective in attracting awareness, engagement, and support. Many of these organizations are facing a critical failure requiring significant business model innovation to achieve their short-, mid- and long-term goals. Design thinking is an avenue for nonprofits to achieve business model innovation by developing new, unique concepts supporting an organization’s viability and the processes for bringing those concepts to fruition. This case study outlines the design thinking process applied to business model innovation for a small, 22-year old, nonprofit approaching critical business failure.

The Not-for-Profit and Voluntary Sector In Canada

The nonprofit and voluntary sector accounts for a considerable part of the economy in many countries around the world, contributing a sizable portion of gross domestic product (GDP)
(Jaskyte, 2015). Because of its long tradition of relying on nonprofit and volunteer organizations to address the needs and interests of its population, Canada has one of the largest and most vibrant nonprofit and voluntary sectors in the world (Hall, Barr, Easwaramoorthy, Wojciech Sokolowski, & Salamon, 2005). In Canada, the nonprofit and voluntary sector accounts for 6.8 percent of the GDP and when the value of volunteer work is incorporated, contributes 8.5 percent of the GDP. When organizations that are hospitals, universities, and colleges are excluded, the remaining organizations contribute 4.0 percent of Canada’s GDP (Hall et al., 2005). The nonprofit voluntary sector in Canada employs almost as many full-time equivalent workers as all branches of manufacturing in the country (Hall et al., 2005). Despite the significant role that the nonprofit and voluntary sector plays in in Canadian life, it faces serious challenges affecting its long-term sustainability.

Michael Hall et al, in The Capacity to Serve: A Qualitative Study of the Challenges Facing Canada’s Nonprofit and Voluntary Organizations (2003), identified a number of issues facing this sector, including problems planning for the future, recruitment of volunteers and board members, and obtaining funding from governments and private philanthropic interests. Those organizations that rely on external funding from governments, corporations and foundations report serious problems (Hall, et al., 2003). Insufficient and inappropriate funding is a significant constraint for many organizations in the pursuit of their missions (Scott & Pike, Funding Matters ... For Our Communities: Changes and Opportunities for Funding Innovation in Canada’s Nonprofit and Voluntary Sector, 2005). In addition, many organizations do not have sufficient financial resources to meet the training and professional development needs of the sector (HR Council for the Nonprofit Sector, 2011). External pressures such as government program reviews, growth of at-risk populations, economic downturns and changes to funding models also present significant challenges to this sector (HR Council for the Nonprofit Sector, 2011). In terms of funding models, the trend toward project funding over core funding has had a considerable impact on the nonprofit and voluntary sector.

This sector’s primary sources of revenue are charitable donations, government funding and earned income. Government and charitable funding is declining and pressure towards earned income is increasing. However, in Canada, charitable regulations prevent many formal charities from earning income (Eakin & Graham, 2009). Most organizations need to rely on more than one revenue stream. The sector profile is one that is struggling to obtain financing from all of these sources (Eakin & Graham, 2009). The challenges of needing external funding from a range of funders was identified as a pressing issue for community-based organizations across the country. Many of these organizations are at a financial crossroads. With traditional revenue sources declining, charities are increasingly looking at alternative ways to finance their nonprofit activities through business income both in areas directly related to their charitable missions, and in areas that are not (Emmett & Emmett, 2015). For example, earned income was the most important revenue stream for nonprofits in Alberta. Many of these groups express concern that insufficient and inappropriate funding presents a significant constraint for these organizations in fulfilling their missions. (Scott & Pike, Funding Matters ... For our Communities: Challenges and Opportunities for Funding Innovation in Canada's Nonprofit and Voluntary Sector, 2005).
Nonprofit and volunteer organizations identify human resources both as one of their greatest strengths as well as an area that presents challenges (Hall, et al., 2003). The most frequently mentioned staff-related problem was insufficient funding to hire enough staff, especially those with specialized skills. The chronic understaffing that faces many organizations in this sector leads to a host of issues such as employee burnout, high rates of staff turnover, and, staff undertaking tasks for which they feel poorly qualified. This issue is compounded by changes in the availability and nature of volunteers. Many organizations are faced with shrinking volunteer pools as well as volunteers who are increasingly unwilling to take on leadership or administrative roles or making a long-term commitment to the organization. The HR Council for the Nonprofit Sector identifies a significant level of stress in the sector, particularly among small and mid-sized organizations (HR Council for the Nonprofit Sector, 2011).

Another significant human resource issue for the nonprofit and volunteer sector is their capacity to undertake strategic planning and development initiatives. Many of these organizations feel forced to concentrate on immediate service and programming issues to the exclusion of organizational management and planning. (Hall et al, 2005). In 2011, the HR Council for the Nonprofit Sector found that the majority of organizations were not spending or did not have access to sufficient financial resources to meet the training and professional development needs of the sector.

These organizations need to explore creative ways to lower administrative costs and to build organizational capacity in financial management, fund development as well as in operations and strategic planning. Innovation is critical for the nonprofit and voluntary sector to respond to these changing environmental conditions (Jaskyte, 2015). In 2016, Canada’s volatile economy has required nonprofit and volunteer organizations to make numerous adaptations including increased reliance on volunteer staff, reduced professional development budgets and increased fundraising efforts. Many organizations have reported increased demands on their programs and services, particularly social service organizations in Alberta (Cave, 2016). Significant business model innovation is required in this sector to adapt to the many resource challenges it faces. Design thinking can provide an effective methodology to achieve meaningful change and innovation.

Design thinking is a foundational reframing process that has a broader vantage point and a more holistic approach than traditional business planning processes. A design thinking mindset is not problem-focused but solution- and action-focused geared toward creating a preferred future. In this context, design thinking provides a platform for innovation that is critical for nonprofit and volunteer organizations’ effective response to changing environmental conditions.

**Case Study: Art à la Carte**

Design thinking is not graphic design, web design, product design or other tactical activities. Design thinking uses abductive reasoning as a third way of reasoning to be added to deduction and induction. A problem-solving cycle is formed, with abduction used for the generation of ideas and solutions followed by deductive reasoning for the predicting of consequences of those ideas, and then to inductive reasoning for the testing and generalization
of proposed solutions. This problem-solving cycle generates data that is then fed back into the abductive reasoning mode for the process to begin again (Johansson-Skoldberg, Woodlilla, & Mehves, 2013). The design thinking process is a holistic cross-disciplinary approach that leverages systems thinking to complex human-centered problem solving (De Guerre, Séguin, Pace, & Burke, 2013). This case study examines the benefits of applying design thinking methodologies (Figure 1) to achieve business model innovation in the context of a small nonprofit organization. The concepts of “abductive reasoning”, “systems thinking” and “human-centered problem solving” play a major role in this case study.

Figure 1: DAIS Design Thinking Model

DAIS Centre for Social Innovation

DAIS Centre for Social Innovation at the Alberta College of Art and Design is a catalyst for collaborative problem solving toward the betterment of society (Figure 2). DAIS offers nonprofit organizations, government and businesses a transformational opportunity to develop solutions using design thinking as a process for problem solving. The Centre works with organizations whose current processes or efforts are not enabling those organizations to achieve their missions and reach their goals. DAIS exists to challenge, reframe, and collaboratively develop solutions through a commitment to design for good. Design thinking is the key differentiator of the DAIS Centre for Social Innovation with respect to other consulting and strategic planning processes.
Art á la Carte

In 2016, Art á la Carte (AALC) was a nonprofit organization in crisis (Figure 3). Art á la Carte is a Calgary, Alberta based, nonprofit organization founded in 1994 that provides artwork and art activities for critical care patients and patients waiting for treatment at Calgary hospitals and healthcare facilities. The organization has one paid staff member – the Executive Director – Debbie Baylin and 35 bedside volunteers as well as 55 event volunteers who collectively have delivered in excess of 63,000 hours of volunteer service. Since its inception Art á la Carte has served over 400,000 patients through their activities in two hospitals and three hospices in Calgary. The organization depends entirely on contributions from individuals, businesses, and charitable foundations to sustain its programs and operations. Art á la Carte does not receive any government funding for either its programs or operations.
Art á la Carte has three primary programs – the Bedside Program, SkyCeilings™, and Create While You Wait™. The Bedside Program provides artwork for the hospital and hospice rooms of critical care patients. Patients are offered an assortment of artworks and are encouraged to share their life stories as they select images that speak to them. The selected images are installed in the hospital room and help transform the space into one which is more comforting. In an atmosphere where the patient often feels out of control, art can serve as a therapeutic and healing tool, reducing stress and loneliness (Rollins, Sonke, Cohen, Boles, & Li, 2009). Art in the healthcare environment can help patients focus on a life perspective that is broader than their disease (Monti, et al., 2006).

Art á la Carte’s SkyCeilings™ are virtual skylights created from photographic reproductions on acrylic panels that convey the color, scale and perspective of actual sky and daylight. The SkyCeilings™ are installed in select treatment areas of the Tom Baker Cancer Centre and the Foothills Hospital in Calgary, Alberta. Integrating art into healthcare settings has a positive impact on patient health outcomes by aiding patients in their physical, mental and emotional recovery, including relieving anxiety and decreasing the perception of pain (Rollins et al., 2009).

Create While you Wait™ began as an opportunity for patients waiting for medical appointments and treatments to participate in individualized creative art activities to relieve stress and boredom. Art á la Carte’s trained volunteers now offer the program on a medical care unit where patients are recovering from brain injuries and strokes. This type of arts programming can provide a more normative environment and offers an opportunity for creativity and self-expression that allows patients to healthfully integrate their experiences and emotions. This art therapy process provides patients an avenue for communication and expression as well as enhancing their quality of life and helping the patient move from a distressed mood to a more quiet and reassured state of mind (Gabriel, Bromberg, Wlaka, Kornblith, & Luzzatto, 2001).

Despite the significant and recognized services Art á la Carte has provided for over 22 years, the organization faces a financial crisis as its primary revenue streams – charitable donations and grants – are not meeting resource needs. The economic downturn that began in Alberta in 2014 is among the worst on record, and charitable giving in Canada in 2016 was at a 10-year low, resulting in fewer and smaller donations and more competition for grants (Cave, 2016). Many Alberta nonprofits are struggling to balance high demand for services with a low supply of donations to support their programs. After a series of unsuccessful grant applications in 2016, Art á la Carte approached the DAIS Centre for Social Innovation to examine their business model and value proposition.

**Research Methods**

Art á la Carte was approaching critical business failure by the end of December 2016. The efforts of the organization to secure grant funding were unsuccessful, a number of key donors did not support the organization financially that year, and the signature fundraising event was
cancelled due to poor uptake. The founder and executive director of the organization contacted the DAIS Centre for Social Innovation for advice on business model innovation. In June 2016 DAIS began a design thinking process with Art á la Carte to develop a series of recommendations and strategies that could improve their business model, and that the organization could implement with their limited resources.

The discovery process began with a “coffee talk” with the Executive director of Art á la Carte, Debbie Baylin. During this session Baylin briefly outlined the vision, business model, and history of the organization, the key challenges and barriers to the continued success of AALC, and her hopes for the future. Cressman and Miyauchi of the DAIS Centre for Social Innovation then provided an orientation to the services of the Centre and developed a process specific to the needs of AALC that the client felt comfortable working with. It is important to note that not one size fits all in this approach and working collaboratively with the client is critical in defining goals and a way forward.

The discovery session helped synthesize our understanding of Art á la Carte and its challenges. We projected back to the client what we heard to ensure both parties had a shared understanding of the key issues. This was followed by a review of Art á la Carte’s company documents and marketing materials, which prompted a frank discussion with the Executive Director around the realities of the marketplace, challenges to success as well as realistic short-, mid- and long-term plans. A working session with AALC was scheduled two weeks later.

In the interim, DAIS conducted an environmental scan including a review of existing and potential competitors in the space, which revealed increasing competition for Art á la Carte in the publically funded sector, particularly with respect to hospital foundations. A detailed digital environment scan was also conducted in order to determine how AALC was connecting with potential audiences through their digital, web, and social media presence. This background research allowed DAIS to conduct a gap analysis to determine what was missing from AALC current operations, what was not adding value, and what opportunities might exist with volunteers and AALC existing and potential clients.

Insights gained from the current state of AALC led to new perceptions of what the organization could achieve. The initial scan included an online share of voice analysis, keyword analysis, search performance analysis as well as a website content and perception audit.

The first working session was comprised of a “Power of Story” presentation followed by a “Why Workshop”. The “Power of Story” presentation outlined what story can accomplish, as well as how art and images provide a means for people to connect on different levels. Particular emphasis in the presentation was placed on how art and images enable transformation, connection, motivation and acceptance. This had strong resonance in terms of the primary client base of Art á la Carte. Research has shown that in the hospital atmosphere patients often feel out of control and the arts can serve as a therapeutic and healing tool reducing stress and loneliness and providing opportunities for self-expression (Rollins et al., 2009).
The “Why Workshop” is based on the idea that if you do not understand why you do what you do, the “what” and “how” of what you do will not be effective. “Why” is core to brand, and critical in understanding an organization’s value proposition(s). “Why” is an essential part of connecting with concepts, messages, services etc. on an emotional and human-centered level. “Why” is the primary enabler of belief creation and behavior change and can provide deep and lasting connections between a brand and its audience. The “Why Workshop” is designed to be a highly collaborative and interactive discovery process that pushes participants to consider what is at the heart of why they do what they do. This act of contextualization is essential given that it is necessary to understand a small universe of contexts to achieve a deep understanding (Wylant, 2016). The outcome of the “Why Workshop” was a foundational document intended to focus and guide subsequent working sessions and to evaluate potential solutions.

In the second working session a review of the findings of the “Why Workshop” was conducted to reinforce and strengthen Art á la Carte’s understanding of the “whys” that have value and strength, to guide decision-making for the organization. This was followed by a facilitated and collaborative business model and value proposition review and analysis (Figure 4). Using the Strategyzer™ Business Model Canvas and Value Proposition Canvas to focus the discussion, AALC was asked to identify the following:

- What products and services are offered to whom?
- How value is created?
- Who benefits and who contributes?
- What are the costs and resources?
- What are the sources of revenue?
- What are the pains and what are the gains?
The business model review was completed for AALC, which identified its three primary audiences – patients, donors, and AALC staff/volunteers. A value proposition review was conducted for the three primary audiences to provide a better understanding of how AALC products and services answer specific patient, donor or staff needs. This exercise provides valuable information regarding the AALC’s gain creators and pain relievers of their products and services, mapped against the gains and pains of the audience segments and the audience needs that AALC’s products and services address.

Once all of the content of the Why workshop and the business model review were analyzed DAIS met again with Art á la Carte for a third working session to provide insights gained from the prior sessions and to conduct a “Possibilities Workshop”.

This workshop was a facilitated brainstorming session to identify new avenues of revenue generation, support, resources and services, so that AALC could develop a more sustainable and practical business model for the organization while keeping the needs of the users at the center of the discussion. The application of a human-centered design process incorporates “people centricity” in all aspects of transformational design (Das, 2016). This human-centered, creative, iterative, and practical approach enables finding the best ideas and ultimate solutions (Brown, 2008). Through the course of the “Possibilities Workshop” a number of new services were identified as well as how existing services could be transformed.

Discussion

The findings derived from the discovery and working sessions were summarized in a presentation for the Board of Art á la Carte that highlighted the ramifications of this new
thinking and new processes that could take AALC to a new level. The presentation of the business modeling work and its potential to transform the organization garnered unanimous support from Board members who agreed that the new directions proposed should be pursued in order to help AALC become sustainable as well as to enable growth of the organization.

When the DAIS Centre for Social Innovation was first engaged by Art à la Carte, the stated focus of the Founder and Executive Director, Debbie Baylin was the art that was provided for critical care patients, and the challenges and limitations of the artwork itself in the controlled and sterile environments of hospitals and healthcare facilities. The Executive Director’s attention was locked within a very limited AALC and patient interaction.

As a result of our work with Art à la Carte, we were able to help the Executive Director to step back from her day-to-day business challenges and to focus on what might be possible. As a result, we were able to move her to consider shifting from an arts model to a service model, a shift that would enable AALC to pursue additional avenues of business and revenue generation through a range of services and to diversify the audiences that would find value in the AALC concept. Our findings also supported a move from focusing solely on critical care to embracing other areas of care including seniors’ facilities, at risk youth centers, and other medical facilities and care providers. In addition, we identified an opportunity in expanding the range of artwork provided for patients to fine art photography.

To augment what is a limited selection of artwork currently available in the Art à la Carte collection we identified the benefits to AALC of supporting artists and photographers through a call for artists and photographers to support AALC in turn. With many artists and photographers wanting exposure and the chance to give back to their community, we recommended that AALC consider expanded engagement with the Calgary creative community to secure artwork. In addition, we recommended that AALC engage area businesses to provide in-kind or financial contributions to making the selection and production of framed work possible.

**Conclusion**

Art à la Carte is at a pivotal point in its history. The organization is on the edge of either being a viable not-for-profit or closing all together. The design thinking process employed with this organization used design sensibility and methods to match the organization’s needs with what is technologically feasible and what a viable business strategy could convert into customer value and market opportunity (Brown, 2008). The design thinking process has helped AALC to determine the viability and limitations of their current model in the short term, and provided options for true business model innovation and new streams of business and engagement opportunities. The key findings were presented to the AALC board in December 2016 and received unanimous buy-in. At its core, Art à la Carte is art therapy and art for good. Art connects, it conjures memories and it helps patients make sense of difficult realities (Ettun, Schultz, & Bar-Sela, 2014). It provides avenues for communication and expression, and it enhances quality of life (Wood, Molassiotis, & Payne, 2011).
Having an opportunity to engage collaboratively with highly qualified, design-minded professionals is invaluable to a grassroots organization such as Art à la Carte. We are honoured and excited to meld innovation and design thinking into a model of success for both organizations. (Debbie Baylin, Executive Director, Art à la Carte)

At this point AALC has made the shift from an arts focused organization to one that emphasizes a patient service model, which has opened additional funding opportunities and resulted in a “Care” grant from the CREB foundation. In addition, the first phase of SEO optimization with a patient service model has been completed and has increased traffic to AALC’s website. A brand-visioning workshop, based on the new service model will be conducted in the next month to enhance the organization’s engagement strategies. DAIS is in the process of identifying additional nonprofits to further examine the potential benefits of applying design thinking to business model innovation and evolution.

**Author Biography**

Alison Miyauchi

Alison Miyauchi is the Vice President, Strategic Enrollment Management at Watkins College of Art. Prior to Watkins Alison was the Acting Vice President, Research and Academic Affairs at the Alberta College of Art and Design in Calgary, Alberta. Alison is the co-founder of the DAISCentre for Social Innovation. She is a graduate of Bryn Mawr College, Pennsylvania and a former Research Fellow of the Smithsonian Institution, Washington, D.C. Alison is a practicing artist, designer and educator. Her research interests include curriculum design, graphic design and design education. Alison has lived and worked in Milan, Italy; Rome, Italy; Glasgow, Scotland, and London, England. She returned to Canada in 1992. Alison Miyauchi was a Faculty member of the Visual Communications Design program at the Alberta College of Art from 1993 to 2012 and was founding Chair of the School of Communication Design.
Scott Cressman is the Chair of the School of Communication Design at the Alberta College of Art and Design in Calgary, Alberta. He is a veteran of Canadian design, marketing, communications and digital industries with over 26 years of experience. Scott is also Director of Integrated Strategy with V Strategies and Strategic Advisor to Alberta Health Services. Scott’s industry experience spans many types of organization including Adobe, Getty Images, WestJet, Agrium, Coca-Cola, Asia Pacific, Kraft Foods, Apple, HP, Microsoft, Pfizer, Roche Pharmaceuticals, Astra Zeneca, Canadian Centre for Energy Information, Canadian Association of Petroleum Producers, Energy Council of Canada, Imperial Oil, Calgary Stampede, Government of Canada – Foreign Affairs, and many others. He is founding partner of Australia-based Creative Skills Training Council, Creative Leadership Forum, Management Innovation Index and The Innovation Ecology. Scott’s research pursues the evolving nature of storytelling in business and the development of communication processes that connect on a deeper human level in brand and marketing communications. To that end he has developed the 100 Stories Process™ and is working with WestJet, Intact Insurance, MNP, Calgary Economic Development and other organizations to understand how storytelling can lead deeper engagement, belief creation and loyalty.
Using Frame Analysis to Organize Designers’ Experience on the Cloud

Julija Naskova, The Hong Kong Polytechnic University School of Design Hung Hom, Kowloon Hong Kong, SAR naskova_productions@hotmail.com

Abstract

This paper demonstrates how Goffman’s frame analysis is applied in a research on designers’ experience with Cloud based digital tools. At the base of Goffman’s structure is the ‘primary frame’ - in this case designers’ experience with computer based digital tools. These tools’ transition to the Cloud initiated by businesses are called ‘fabrications’. Goffman’s ‘structural issues in fabrication’ such as ‘retransformations’ and the ‘nature of recontainment’ are also discussed through contemporary examples. These fabrications are used or ‘keyed’ by ‘active agents’ from various design fields. The data collected showed different levels of understanding of Cloud technology and the application of various tools in everyday design practices. Thus, the interviewees were clustered into three groups - designers, developers and artists. Their experiences form the creative, technology and experimental frame derived from keying of the primary frame. Design researchers can selectively borrow elements from frame analysis’ complex structure to build an effective user experience narrative.

Keywords: Dramaturgy; Cloud; UX; Frame Analysis; Digital Tools; Erving Goffman.

The ever-changing nature of the Cloud, the onslaught of digital tools as well as new versions and packaging of old ones make it hard for designers to create firm understanding of the Cloud. This research encompasses digital tools users from various design fields such as web and mobile design and development, graphic design, architecture, industrial design etc. Their experiences conditioned with the transition of digital tools to the Cloud are different. The data collected from such a diverse group presents an organizational challenge. While symbolic interactionist theory helps to analyze human computer interaction, it doesn’t offer strategies for analyzing data coming from diverse sources. Goffman’s frame analysis offers the solution to present each groups’ experience as a distinctive frame.

Presently coined as one of the greatest sociologist of the 20th century, Goffman’s work is centered around the ways people interact. His first book The Presentation of Self in Everyday Life presents the idea that people build their public persona similarly to the way a character is developed for a dramatic piece (Goffman, 1956). His use of the theatre as a metaphor for real life led to the rise of dramaturgical sociology, that examines the context of human behavior rather than the cause. In this book, Goffman uses the term ‘framing’ to describe how people alter their behavior based on the place, time and observers.

In his 1974 book Frame Analysis; An Essay on the Organization of Experience Goffman increases the application of ‘framing’ to be used as an approach in analyzing certain shifts in paradigms (Goffman, 1974). Frame analysis has been applied successfully to analyzing news reporting, political events and environmental agendas by presenting different approaches to the issue as different framing (Knight, 2010). While dramaturgy was applied for human
experience studies in other fields, Goffman’s frame analysis has only been scarcely referenced in design research as far as the author of this paper is informed. This paper demonstrates how Goffman’s framing concepts can help to organize designers’ experience on the Cloud.

**Literature Review**

Symbolic interactionism is the theoretical framework of choice in many studies on human experiences with computers. At its core are Blumer’s (1969) three principles: people act towards things according to the meaning they have for them, the meanings arise from interaction with other people and during the interpretative process these meanings are altered.

Lee (2009) uses these principles to address role playing in the mediation between culture and co-experience. Co-experience was coined in an earlier research by Battarbee (2003) when mobile SMS technology offered a new format for social interaction. She references Dewey (2005) and Goffman (1956) to support the idea that the way people interact is closer to drama than sociology or psychology.

Jordan (2002) states that when people interact with computers they have expectations and ideas of how the interaction is supposed to play out. This resonates in Wilson’s (1980) statement that theatre goers generate expectations while observing a performance. In the early 90’s, Laurel (1991) perceived the theatrical structure consisting of situations, characters, actions and reactions as appropriate for mapping people’s experience with computers. Blumer’s three principles resonate the dramaturgical analysis of character and action as established by Stanislavsky’s technique (Naskova, 2016).

From 1929-1932, Blumer conducted research on how young Americans are affected by movies, concluding that their lives’ focus was redirected from working class or ethnic communities towards a consumer culture (Digital History, 2017). In Chapter 10 named “Schemes of Life”, Blumer (1933) states, “motion pictures fashion the minds of grade school children in an appreciable way by providing both specific ideas and a general framework of thought”. Clough’s (1988) review of this research concludes, “Blumer’s theoretical statement of Symbolic Interactionism was a proposal for an observational methodology that drew on filmic representation but distinguished itself as scientific and objective by distancing itself from the cinema and any traces of its gendered imagery”.

Herbert Blumer was Chair of the Department of Sociology at the University of California, Berkley, when Erving Goffman became an Assistant Professor in the early 1958 (Smith, 2006). While Goffman was exposed to Blumer’s work, he hasn’t referenced it in his seminal book on frame analysis. This might be explained by Gonos, who states that in opposition to the interactionist framework, Goffman’s is a structuralist one (1977). Cahill states that while Goffman was influenced by symbolic interactionism his contribution to this field is much more significant (2007, p. 174).

In an interview with Verhoeven (1980, p. 318), Goffman answers some of these questions, “I guess I’m as much what you call a symbolic interactionist as anyone else. But I’m also a structural functionalist in the traditional sense”. The term symbolic interactionist results from
social circumstances rather than the nature of the field, explains Goffman. It was resurrected from a Blumer’s footnote eight years ago and applied to his graduate student group of late 40’s (Verhoeven, 1980, p. 319). While he finds Blumer’s work very sympathetic, Goffman distances himself from his colleagues. Despite the influence, Goffman concludes that his sociology is more traditional and if labels are necessary, he prefers Hughesian sociology.

The frame analysis’ dramaturgical structure might have been influenced by Goffman’s older sister who was a character actress (Cavan, 2011), his position at the Canadian National Film Board (Battistella, 2014) or his assistance on the 1948 Big Sister research project by Warner and Henry (Low & Bowden, 2013). According to Gonos (1977), it is an effort to abstract the frames within which life takes place in contrast to the symbolic interactionists close study of participants’ unique situations. In Verhoeven’s interview (1980), Goffman maintains his reservation towards labeling, “The term dramaturgy I can’t take all that seriously… If you come to it as somebody who has lived through it, you get quite a different view”. He further likens how outsiders depict experiences not lived to “pictures which are generated by pictures makers”, thus contradicting his impartiality towards dramaturgy.

Frame Analysis

Use of technology is scarcely referenced in Goffman’s frame analysis. He speaks about the use of wiretapping devices for monitoring and once mentions a newspaper articles about the use of computer strategy to beat the game of twenty-one at a casino (Goffman, 1974, p. 180). With research subjects such as vaudeville-like nightclubs and casino con games, he builds his dramaturgical structure while referencing cases from the United States criminal justice system. His structural elements are named in the language of the era and sometimes challenging to translate into contemporary terminology. Therefore, adapting his theoretical framework to the analysis of designers’ experience with Cloud based tools presented many challenges.

This research started with a case study of Dreamweaver CC, how Adobe promotes the Cloud based version of the tool and the new functions introduced. Based on the findings, a questionnaire was devised with eleven questions. It was then distributed to thousand designers featured on Béhance, employing the netnographic research. The later according to Kozinets (2010) is a participant-observational research targeting online communities. It resulted in a low response rate, and after separating twenty responses from China, only thirty-five responses from other parts of the world were considered. The same questionnaire was then used as a guideline for thirty-one in-person semi-structured interviews. Additional participant-observational research was conducted by attending meetings organized by user experience and other target groups. These were paired with archival studies of various digital tools as well as online articles.

In the nine interviews featured in Table 1, the active agents responded according to Entman’s logic (1993), “Receivers’ responses are clearly affected if they perceive and process information about one interpretation and possess little or incommensurable data about alternatives”. Jane, Toro and Bijan covered themes concerning functionality and creativity, Brian, Dave, Markus and Jovan spoke about security and technological issues, while Lorenzo
and Anita were promoting disobedience and experimentation in their artworks. Goffman’s frame analysis is applied to building the structure behind frame creation, without a detailed user experience evaluation. The latter two form the inductive part of this paper’s research strategy conditioned by the interview questions which represent the deductive part (Matthes & Kohring, 2008).

Primary Framework

“The primary frameworks of a particular social group constitute a central element of its culture” states Goffman, from which emerge “principal classes of schemata” (1974, p. 27).
While there are multitude of frameworks, an operating fiction must be accepted even temporarily to make sense of a certain activity, thus necessitating the establishment of a primary framework (Goffman, 1974, p. 26). This research starts with the ‘primary framework’ – how designers’ used computer based digital tools for their work – the bottom layer in Figure 1. This is the experience that created ‘sense of reality’, or how things should be when using digital tools.

The sense of reality is different depending on the age of research participant. Seasoned designers counterpointed it with their pre-digital era experiences with physical tools. They were working in the design field using tracing tools, paper and pencil when digital tools changed their workflow. Young designers have difficulty differentiating between computer and Cloud based digital tools. The seamless integration of the two paired with uninterrupted Internet service and simplified mobile tool versions blur the boundaries. Nevertheless, the experience with design tools that resided on personal computers will be considered as the primary framework.
Active Agents and Frames

In this research, the interviewees or ‘active agents’ are segregated into three groups based on their design activity and understanding of Cloud technology: designers, developers and artists. Upon engaging in a strip of activity, the active agents try to make sense of it. This leads them to answer the question “What is it that’s going on?”, thus establishing the group’s ‘framework of frameworks’ - its cosmology or belief system (Goffman, 1974, pp. 26-27).

Jane, a self-taught web designer believes that her sense of design gave her an edge over other desktop publishers:

In the first several years (late 80’s) that I was doing ‘desktop publishing’, I was very concerned because I had a fine arts training. I didn't have graphic design or the commercial artist training and everybody that had a computer was doing desktop publishing and they didn't know jack shit! They were using twenty different fonts just because they can, things looked awful and they didn't have any sense of design. So, I was very hesitant to call myself graphic designer for quite a while.

Jane was an early adopter of digital tools, which enabled her to have a private business and an independent lifestyle. Sometime in 2005 she chose WordPress as her website creation tool and stuck with it because she knew it won’t disappoint her like the other tools. Jane likes WordPress because it helps her to create professionally looking websites with a limited knowledge of PHP. She knows how to add basic commands to the code, but for more complicated changes she calls the ‘code ninjas’ for help. She represents the designer group of active agents interviewed for this research. On Figure 1, their new experience is contained within the creative frame.
An interview with Brian, a WordPress developer reveals that this tool is robust enough for someone who likes to code websites from scratch:

When I first started coding (late 90’s), I had no idea how to fix cross browser inconsistencies, but slowly I figured it out. Till this day, you can give me any design and I can code it in HTML, CSS and JS. It is more a matter of practicality. Especially in programming, everything is possible… it’s only a matter of how much time you can put into it.

WordPress’ easy to use interface is perfect for customers who want to update their website’s content without paying Brian. Instead of using WordPress themes, he has developed his own frameworks suitable for different types of websites. Brian is an example of the developer group of active agents in this research, whose new experience is signified by the technology frame in Figure 1.

The third group of active agents is the most eclectic one, a mix between professional technologists and designers who are also active as artists. They prefer to use open source tools or code from scratch, applying Internet technologies in unusual ways while defying businesses’ expectations. An Italian artist called Lorenzo stated in an interview:

You know, I have this phone, but there is also an iPhone, which is more functional. But I don’t like to follow the companies, because it is a kind of a vicious circle and you can go crazy. But I know that eventually I’ll need to update everything.

Lorenzo can work off-the-grid because most of the time he isn’t collaborating with other designers. His projects capture instances when technology fails to disguise its true nature. He likes to take screenshots of pixelated mishaps, as a proof of the computer’s artificiality. Novelty and constant explorations drive this group’s activities. Their unique experiences fall under the experimental frame on Figure 1.

Keyings and Fabrications

Goffman defines ‘keying’ as, “The set of conventions by which a given activity, one already meaningful in terms of some primary framework, is transformed into something patterned on this activity but seen by the participants to be something quite else” (1974, p. 43). Keying is the transformation of a designing activity initiated by Cloud technologies. Besides re-learning how to use their transformed toolbox, designers now need to navigate through new computing models such as SAAS (software as a service) while dependent on reliable Wi-Fi connection.

Unreliable Internet service can delay the adoption of Cloud technology. In certain parts of the World due to poor Internet connection designers can only use bootleg copies offline, “Our Internet connection is very low so we don't use Adobe as Cloud because it doesn't work with our Iranian connection. I use a regular or non-connection version of Photoshop, also we don't have copyright (software licensing)” – disclosed Bijan, a Tehran based graphic designer.
While keying is the basic way an activity is vulnerable to transformation, Goffman offers an alternative in a transformational vulnerability called ‘fabrication’. He further clarifies, “I refer to the intentional effort of one or more individuals to manage activity so that a party of one or more others will be induced to have a false belief about what it is that is going on” (Goffman, 1974, p. 83).

Goffman classifies the deception engineers as operatives, and the contained, or taken in the fabrication – dupes, suckers and pigeons, “This is collusive communication, those in on it constitute a collusive net and those the net operates against, the excluded” (1974, p. 84). Further he specifies that, “for those in on the deception what is going on is fabrication; for those contained, what is going is what is being fabricated”.

Fabrications are categorized as ‘benign’, ones that don’t harm the contained party and ‘exploitative’, ones that are clearly damaging to the interests of the contained. The way to distinguish them according to Goffman is that the exploitative ones can be subject of legal proceedings, for example in the case of false advertising (1974, p. 102). Under benign fabrications, Goffman presents cases where benign fabrications are ‘strategic’. He further specifies that two elements are involved, “a moral one pertaining to the reputability of the deceiver and a strategic one pertaining to the misdirectings of the dupe’s perception and (consequently) his response”.

According to Dave, a senior Cloud technologist from Hong Kong, “The Cloud, more importantly, the ability to delivery services via the Internet has been around for a very long time and one of the first services you could get was email”. At the beginning, there was the benign Internet, limited to providing email services for one flat utility fee. It took some years for it to become the Cloud, a complex business model that delivers various services over the WWW, each for a cost additional to the price paid for the Internet as public utility (Kang, 2016).

Today Cloud services providers can challenge net neutrality, whereas the non-regulated nature of the Internet offers many possibilities for abuse (CMS IT Services, 2015). In this case, big Cloud providers are the deceiver, but their reputation is hard to challenge mainly because of the non-existent legal base (Net Competition, 2014). Legal proceedings are carried daily by private entities against serious damages done by Internet businesses and malicious users, but the technology changes faster that judicial protection against misdirectings can be put in place (Spinello, 2014).

Corporations keeping secrets from their competition in-order-to protect their interests are given as an example of strategic fabrication (Goffman, 1974). Goffman doesn’t deny that those kept in the dark might have their interests threatened by this behavior. The Cloud is presented as a safe place to store your data while hard drives can get damaged by floods, earthquakes and other failures (Taylor, 2014). Occasionally, data breach cases remind us that someone else is not invested in protecting our data as much as we were made to believe (Wakabayashi & Yadron, 2014).

Designers get overwhelmed when trying to comprehend all the new issues arising from their
use of Cloud technology because most designers are not technologists. The Cloud is advertised aggressively while essential information such as security issues, protection of intellectual rights and availability of legacy versions is neglected. All these issues can affect designers negatively where they have little to no say in the matters that affect their livelihood.

Structural Issues in Fabrication

Retransformations
The primary frame, in this case use of digital tools, is fabricated by businesses transitioning their digital tools to the Cloud. This transformation comes with information on ‘what is new’ posted on the software’s website together with videos of evangelists’ demonstrations and options for online support (Adobe, 2017). Designers then transform the transformation by streamlining the way they use the tools to best suit their needs. According to Goffman, “whatever it is that makes untransformed activity vulnerable to transformation makes transformations even more vulnerable to retransformations” and this unavoidable layering of the primary frame creates a structure (1974, p. 159). The retransformation can also be fabrication of the keying, or fabrication of the fabrication, with different correlations between benign and exploitative culminating into Goffman’s ‘big con’.

The Nature of Recontainment
In the case of a ‘big con’, Goffman talks about the duped being recontained in forms standard for our society. The first one is ‘secret monitoring’ where “basic assumption about social life is violated by these various forms of monitoring” (Goffman, 1974, p. 168). He further argues that places that people like to think of as private are usually those that are bugged, because here individuals abandon their public persona and behave in a way that discredits them. Goffman concludes that, “Any monitoring of any individual’s behavior that he does not know about will then have a discrediting power; all forms of secret surveillance function to undermine later activity, transforming it into a discreditable performance” (1974, p. 169).

The Cloud offers possibilities for monitoring, and businesses are taking advantage of their access to users’ data. Anita was apprehensive of this issue, “No, you have no control about privacy. It is an illusion, you know? Google it's for free because it has a reason to be free and all the free applications they have a reason why they are free”. Data mining, artificial intelligence, machine learning are all computational processes enabled by big data collected from the Cloud (Neves, Schmerl, Bernardino, & Camara, 2016).

Most designers are not aware of the possibilities for surveillance that come with the use of Cloud based tools, thus unable to give informed consent. Especially, they are not aware when they are giving permission to businesses to collect their data, since most privacy policies contain an opt-out clause (Adobe, 2017). The latter can be used to apply control and undermine designer’s privacy (Nagenborg, 2011). Even with informed consent, Nagenborg argues that online surveillance can create ethical issues not only limited to privacy.

Designers are conditioned to present their work on social media because as Toro, a Japanese illustrator puts it, “As a creative person today, not using at least one of these platforms is a huge waste, a career suicide”. Most designers didn’t express concerns about their intellectual
property being misused. But some designers do track copyright infringements where Google reverse image search helps find copies of similar images posted on the web (Stone, 2014). Designers working for large design companies stated that their company is keeping sensitive data on internal storage systems and not on the Cloud. In most cases, intellectual property rights on the Cloud are only apprehensive about misuse of corporate data (Cidon, 2015).

Another form of recontainment is ‘penetration’ or “the process whereby an agent who is disloyal to a team exploits legitimate (as opposed to clandestine) access to social settings in which the team’s strategic or dark secrets are unguarded or their discrediting conduct is observable” (Goffman, 1974, p. 170). Goffman further explains that participant observation, one of the research techniques applied in this paper as well, is one type of penetration. Firsthand gossip, arguably what most ethnographic research happens to be, is according to Goffman a betrayal of the penetrated circle.

For this research participant observation was conducted by attending networking meetups, presentations, workshops, conferences, hacking camps, design swarms targeting active agents such as designers, developers and artists. Informal interviews were conducted with some of the participants and some of them were recruited for a formal semi-structured interview. The common understanding is that this sharing of information is conducted for the benefit of the group, if not society at large.

Ultimately, how the information is going to be distributed is at the discretion of the university sponsoring this research, what leads to the third category of recontainment. “The activity through which a discrediting act is called forth by a provocateur on the grounds that he is a proper person with whom to share the secret world” is considered an ‘entrapment’ by Goffman, an active form of penetration that induces the vulnerable activity (1974, p. 172).

Besides universities sponsoring the penetration of a group, businesses that sponsor gatherings of a specific group can also be-seen-as provocateurs. Cloud providers employ evangelists to present new services at user groups meetings, answer questions, mingle and recruit collaborators. Developer suites are supported by most major Cloud operators such as Microsoft Azure (Microsoft, 2017), Apple Xcode 8 (Apple, 2017), Amazon Developer (Amazon, 2017), Autodesk Developer Network (Autodesk, 2017) and others. In most cases, they offer developing tools and technical support in exchange for developers making their work accessible.

The Cloud has expanded the scope of work for technicians who coordinate these suites as well. An interview with Markus, a software developer for a network developer suite revealed:

  In the past when we were only focusing on desktop products, the situation was a bit easier. Every person could be an expert just in that product and focusing on functions inside that product. It was a closer eco system than now. Now with the Cloud, we need to make any solution integrable and it takes more time experimenting, writing demos and samples. Showing something that might be interesting, write a blog… Sometimes we keep using it, sometimes it doesn’t go anywhere.
All three forms of recontainment are subject to legal and moral scrutiny, and discussions of how far can these activities go before they become unethical are endless. The Cloud supports activities that challenge values such as intellectual property, privacy, right of use, etc. On the other hand, the rapid development of internet technologies would have never happened if it wasn’t for this open sharing of information between different active agents at the expense of personal interests. It is undisputable however that the Cloud introduced a set of ethical precedents that are hard to address due to its rapidly changing nature.

Concern over Cloud security was expressed by Jovan, an American designer and technologist:

Security is a huge con for a lot of Cloud related services. It's amazing to me that we haven't seen companies being sued into oblivion over some of the very massive security issues that the companies have allowed to occur. They’ve somehow kept the focus on the hackers, when this is almost completely the fault of bad software and a lack of focus on making security be a major product goal.

Goffman would have been amused by this version of a big con. A company is selling a product that when proven defective it blames it on those exposing the defect. On the other hand, when considering that behind every technological system are the people who maintain it, the possibility of human error will never go away.

**The Theatrical Frame**

“In considering legitimate stage performances it is all too common to speak of interaction between performer and audience” stresses Goffman, adding that this impedes the analysis that should be made of this interaction (1974, p. 127). He further explains that it, “conceals the fact that participants in a conversation can be said to interact too, conceals, indeed, the fact that the term ‘interaction’ equally applies to everything one might want to distinguish”, concluding that “the first issue is not interaction but frame”.

As illustrated in Figure 1, there is overlapping between the three active agents. Many artists make a living as designers or industrial engineers, there are web developers who started as designers, and architects who practice digital photography. The cross-hybridization between art and sciences, as well as the many new roles created by Cloud technology, makes it even more difficult to generalize about the designers’ experience.

When the make-believe world of a play is contrasted by the real world, we find that the outcomes are a bit more problematic, states Goffman (1974, p. 133). The role of fabricators in this case, is to “play the world backwards”, or arrange for a certain outcome that others will otherwise perceive as chance. How individuals respond to this depends on their ‘information state’, concludes Goffman.

The actors in a play are pretending to have different information states thus performing keying of a fabrication. The active agents in this research are at different information states when it comes to how businesses have fabricated digital tools with their move to the Cloud. Designers’ level of information state influences their string of activities and dictates how they frame in Cloud experiences. Nevertheless, most research treats designers as a cohesive
group while offering a one-sided view on their experiences.

**Discussion**

Rooted in symbolic interactionism, frame analysis presents itself as an applicable user experience research method. Based off Goffman’s frame analysis, the field of media and communication studies developed its own theory and methods called news framing analysis (D'Angelo & Kuypers, 2010). Frame analysis is also used in learning for environmental policy making in Europe (Nilsson, 2005).

The general meaning of the term frame as a structure supporting a specific system of beliefs has been used by certain researchers to indicate theories independent of Goffman’s frame analysis. In design, Dorst (2015) introduces frame innovation, providing an outline for designers on how to approach and solve design issues. Ylirisku (2013) draws on Goffman’s and other theories to create a new method called Framing Analysis of Design Articulation (FADA) applicable “for the investigation of project specific learning”.

Sociologists such as Hill (2014) believe that “frame analysis has extraordinary wide applicability” once it is carefully read and an “operational grasp of Goffman’s rudimentary concepts” is achieved (p. 6). He further calls it a “systematic epistemological treatise” and states that to apply frame analysis one must “work through Goffman’s meticulous prose, paragraph by paragraph, definition by definition” (Hill, 2014).

Some sociologists dispute frame analysis as a valuable research method that is reproducible and teachable (Smith, 2006, p. 55). For some, its complexity presents a research challenge. As stated by Prof. Ilpo Koskinen, using frame analysis is like going to the supermarket and picking up elements that apply to one’s research (personal communication, March 10, 2017). To make it a successful trip, the researcher should take along a detailed shopping list and collect enough data that represents reliably the empirical world they are researching.

Goffman doesn’t offer a data collection strategy, but he stresses that interviews should be paired with participant observation (1974). In addition to primary qualitative research techniques Hill (2014) uses library and archival research (p. 17). Applying the iterative process of data collection as proposed in grounded theory can supply frame analysis with quantity of data needed to create a meaningful outcome (RWJF, 2008).

**Conclusion**

Extensive data collection that covers various aspects of the research subject is necessary for frame analysis to be complete. For this research, there was so much data collected from various sources that a case of data drowning appeared to be imminent. Goffman’s frame analysis, with its expansive scope of ideas and categories offered a way out of the chaos, proving to be an applicable knowledge-producing system. Unfortunately, as far as the author of this paper is informed, application of Goffman’s frame analysis as a theoretical framework in design research is non-existent.
What is practical about frame analysis is that it can be applied selectively, and elements that cannot be identified can be left out as long as the narrative is complete. In general, it is impossible to have a 100% error proof method, or one that is fully applicable. The meaning always comes with application, and considering how fast changing Cloud technology is, the analysis will always lag behind the current state of affairs. Nevertheless, this theoretical framework offers a possibility to narrow the gap by analyzing the structures that influence human computer interaction, and this has been missing from most user experience research.

Author Biography

Julija Naskova
I hold a BA in Cinema from SFSU and an MFA in Film Directing and Production from UCLA School of Film, Theatre and TV, where my student films were distributed to festivals. After graduation, I pursued photography and installation projects while working in film production and post-production. In 2008, I joined the field of digital media entertainment as the production, delivery and archiving tools were being developed. Inadvertently, I ended up doing user experience research and design of the tools. Since then, I have been attending relevant meetup.com events, reading articles and taking classes. In 2014, I commenced PhD studies at The Hong Kong Polytechnic University School of Design and my thesis is How Designers Frame in Cloud Experiences. I am researching how designers’ experience with digital tools has evolved in the last few decades. I am interested in the role that businesses play and the ways that designers can have agency in the relationship. During my research, I discovered Erving Goffman’s work and the possibility for application of dramaturgy to data analysis. I am adapting his work, and especially his book Frame Analysis: An Essay on the Organization of Experience as the theoretical framework for my thesis.
Designing with and for People with Dementia: Developing a Mindful Interdisciplinary Co-Design Methodology

Garde, University of Twente Ben Salter, University of Wolverhampton Michelle Bosse, Technische Universität Dresden Ingeborg Griffioen, Panton Healthcare Design

Abstract

This paper reports on the development of a mindful interdisciplinary design methodology in the context of the MinD project research into designing for and with people with dementia, which takes the particular focus on supporting the subjective well-being and self-empowerment of people with early to mid-stage dementia in social context.

Existing research is for the most part focussed on functional support and safe-keeping from the perspective of the carer. References to decision-making and empowerment are predominantly related to action planning for dementia care or advance care planning. References to care and social interaction show that caregivers tend to take a deficit-oriented perspective, and occupation of people with dementia is often associated with doing ‘something’ with little focus on the meaningfulness of the activity. Furthermore, caregivers and people with dementia tend to differ in their perspectives, e.g. on assistive devices, which might offer support.

The MinD project, has therefore developed an interdisciplinary co-design methodology in which the voices to people with dementia contribute to better understanding and developing mindful design solutions that support people with dementia with regard to their the subjective well-being and self-empowerment a well as meaningful and equitable social engagement.

This paper discussed the design methodological framework and methods developed for the data collection and design development phases of the project, and their rationale. It thus makes a contribution to interdisciplinary methodologies in the area of design for health.

Keywords: mindfulness, mindful design, co-design, methodology, public and patient involvement (PPI), interdisciplinary
With ca. 10.9 million people affected by dementia in Europe, with numbers set to double by 2050 (Prince, Guerchet and Prina 2013), with 20 million carers, and with no cure in sight (Alcove 2013: 13), research into dementia is a priority of the European Commission (EC), (OCED 2015: 20). Characterised by progressive memory and cognitive degeneration (Alcove 2013: 13), it is widely recognised that people with dementia experience a range of behavioural and psychological problems subsequent disadvantaged or discriminated status, and reduced social engagement. Therefore, research into care and support to improve the quality of life of people with dementia is essential, to encourage and enable and offer opportunities for them to engage in activities that are in line with their interests and experiences (Alcove 2013: 22; Alzheimer’s Society 2013; Alzheimer’s Australia 2008, Victorian State Government 2014).

However, currently there is very little research into the quality of life of people with Dementia. Existing studies are largely focussed on functional support and safe-keeping from the perspective of the carer: References to decision-making and empowerment are rare and often related to action planning for dementia care, advance care planning or treatment options (e.g. Fetherstonhaugh 2013:144). Furthermore, caregivers and people with dementia tend to differ in their perspectives, e.g. on assistive devices, which might offer support (Gibson et al., 2015). Initial insights about care and social interaction from our own work indicate that caregivers also tend to take a deficit-oriented perspective, and occupation of people with dementia is often associated with doing ‘something’, with no focus on meaningful engagement). Some smaller studies which do offer insight into the wellbeing and empowerment of people with dementia, related to exercise programmes (Olsen et al., 2015) or to social eating (Keller et al., 2015), show positive responses and the appreciation of people with dementia of being recognised, respected and socially connected.

The MinD project therefore takes its focus on subjective wellbeing, self-empowerment and meaningful social engagement to recognise the importance and value of meaningful activities and social interactions, and the contribution that people with dementia can make to society. It does so by bringing together and applying both mindful approaches from psychology (Langer 2010, Kabat-Zinn 2003) and design (e.g. Niedderer et al 2014a, b) to put the individual’s wellbeing in everyday social life at the centre. Mindful design approaches can offer both, therapeutic practices as well as novel solutions and implementation of mindful approaches into everyday life.

One important aspect in studies about people with dementia is that often they are not included, but data collection is done through carers. In order to enable the voices of people with dementia a voice and increase their level of empowerment also with research processes, it is important to include them as valued participants. Therefore public and patient involvement (PPI) and co-production, especially in an interdisciplinary design and healthcare context, is important to bring together, adapt, adopt, amalgamate and develop suitable methods to facilitate people with dementia as active partners in each step of the research. The MinD project, which develops through three stages (data collection, design development and implementation evaluation), has

---

1 Our work includes: 21 interviews with people with dementia and 10 interviews with carers across three countries (Germany, The Netherlands, Spain) conducted between September 2016-January 2017, publication of final results forthcoming.
therefore co-developed an interdisciplinary co-design methodology spanning the three stages to afford a voice to people with dementia. The aim is for all partners collectively to better understand and develop mindful design solutions that can support people with dementia with regard to their subjective well-being and self-empowerment in social context.

This paper discusses the mindful design development framework and methods developed for the data collection and design development stages, including data collection design tools, analytical mindful design framework, design ideation and co-design activities conducted during the project, and their rationale.

The role of mindfulness and design in dementia care

This section discusses social engagement, self-empowerment and subjective well-being, first in the context of dementia care and support, second in relation to mindfulness, and third the role of design in its implementation.

Dementia and social engagement

People with dementia are regularly affected by behavioural and psychosocial symptoms of dementia (Gautier et al 2010, Manthorpe and Moniz-Cook 2008), either as a cause of Alzheimer’s disease, of Stroke (multi-infarct dementia), or other dementias (e.g. Lewy-Body, Pick's or Binswanger's disease), (Barker et al 2002). In addition, they often face various difficulties of engaging in social context, e.g. through difficulties in planning, organizing, thinking strategically, paying attention to and remembering details, managing time and space. They also may have memory impairments, concentration difficulties, and a decreased ability to learn new skills, take initiatives and get motivated (Baddeley, Kopelman, and Wilson 2002).

In social context, this can cause difficulties in recognizing, relating to, and empathising with other people because individuals are struggling with their identity and with coming to terms with their circumstances. These difficulties often lead to social and emotional insecurity, which can e.g. result in aggressive behaviour or in withdrawal, or in being disadvantaged, devalued or discriminated against, posing a challenge for interacting socially and resulting in reduced social engagement. Social contact, however, is central to stimulating mental faculties and emotional balance, and maintaining quality of life (Mendes de Leon et al 2003). While existing research is largely focussed on functional support and safe-keeping as discussed above, our research focuses on the aspects of subjective wellbeing and self-empowerment in social context to encourage more meaningful social engagement. By subjective wellbeing, following (Steptoe et al 2015, Deci and Ryan 2008, Waterman, 1993, Seaborn, 2016) we refer to a person’s self-perception with regard to both hedonic and eudemonic aspects, i.e. their happiness and self-actualisation, rather than any objective health measures. Subjective well-being, i.e. contentment with one-self, has an important relationship with perceptions of self-empowerment, in that one can see (perceptions of) self-empowerment either as part of and contributing to wellbeing or as a result of well-being. Following Rotter (1990) and Langer (2010), self-empowerment refers to a person’s feeling of responsibility and of being in control of one’s own life. Both, wellbeing and perceptions of self-empowerment, are important factors that influence and are influenced by social engagement, i.e. by having social contact and interaction with others, in that

2 In the following simply referred to both as ‘subjective wellbeing’ or simply as ‘wellbeing’
meaningful social engagement can be important for subjective well-being, while feelings of self-empowerment can help build confidence for engaging socially and feeling self-value as one of the constituents of subjective well-being.

**Self-empowerment and subjective well-being through mindfulness**

Mindfulness is closely related to and can be beneficial in enhancing perceptions of subjective well-being and self-empowerment. The understanding of mindfulness is dominated by two major theoretical approaches.

The first, by Kabat-Zinn (2003), defines mindfulness as ‘the awareness that emerges through paying attention on purpose, in the present moment, and nonjudgmentally to the unfolding of experience moment by moment’ (p. 145). Meditation-based, it is often used for therapeutic purposes, such as the Stress Reduction and Relaxation Program (SR&RP, see e.g. Winbush et al., 2007; Goyal et al, 2014 for reviews). The aspect of focusing on ‘being-in-the-moment’, as not requiring memory, also can offer empowerment to people with dementia.

The second understanding is also strongly committed to the notion of being in the present moment. Associated with Ellen Langer’s work on mindlessness and choice, this approach presents mindfulness as the process of actively making new distinctions by not relying on automatic categorisations (Le et al, 2014). With this approach, mindfulness is nurtured by maintaining an orientation in the present, an alertness to distinctions, a sensitivity to different contexts, and an openness to novelty (Langer, 1989, 2010). In addition, Langer has shown that offering people responsibility and choice increases their well-being (Langer 1989: 123).

Mindfulness is therefore increasingly used for therapy in the context of dementia care, both for people with dementia and their carers, and results have indicated reductions of stress and depression in both groups (McBee 2012, Monin and Schulz 2009, Oken et al 2011, Whitebird et al 2012). Mindfulness therapeutic approaches have also begun to be implemented through design with good results (e.g. Chittaro and Vianella, 2013). Cognitive mindful approaches have already been applied successfully in therapeutic and in everyday contexts (Le et al, 2014: 149-51; Djikic 2014; Manicavasgar et al 2011). In distinction to these approaches, we will look at the use of mindfulness in everyday social contexts and how they can be embedded through design.

**Design for dementia**

This section reviews the current use of design with regard to dementia care. Currently there are a number of design approaches, which address various aspects of dementia. They can be organised into four categories of non-pharmacological interventions (O’Neil et al 2011):

Cognitive/emotion-oriented interventions: There are a number of interventions and products related to reminiscence therapy that seek to stimulate memory, such as REMPAD, which is a new software tool to create multi-media content that can be used to connect carers and residents with memories from the past (Yang et al, 2013). There are also environmental interventions aimed at helping with orientation, for example, reducing clutter or improving signage and colour contrasts (e.g. Iyendo et al (2016).

Sensory stimulation interventions: Sensory stimulation interventions are mainly of a therapeutic nature. They include for example aromatherapy (e.g. ‘ODE’ fragrance system, Design Council
2012), light therapy (Thieme et al. 2013), tactile pillows and textiles (Pakhchyan, 2013, Treadaway and Kenning, 2016, Ten Bhömer, 2016), or Snoezelen multisensory stimulation (Weert et al., 2005). The various approaches are being used to stimulate tactile or other senses and by doing so to stimulate interest, discussion and/or reminiscence.

Behaviour management techniques: Design interventions available in support of behavioural management include, for example, the above mentioned ‘ODE’ fragrance system to promote eating. Other interventions address personal safety, such as the personal alarm ‘Buddy’ (Design Council 2012) or the ‘Safe House’ sensor system (Kinney et al., 2004) through sensor tracking linked to alerts. Yet others are aimed at enabling independence, e.g. MyLife project (MyLife 2016), COGKNOW (Meiland et al., 2012) or the ReMind Me App (Innovate Dementia, 2015). All three offer different types and levels of software to help people with early stage dementia to keep track of their daily routines and activities and stay connected.

Other psychosocial interventions include various approaches not fitting under the three categories above, such as animal-assisted therapy and exercise, or interventions for more general wellbeing and social engagement. Examples are the ‘dementia dog’ scheme (Design Council 2012) where trained dogs help people with dementia with orientation when going out, and they act as companions and help e.g. with reminding of eating times; the Alzheimer’s cafés (Alzheimer Europe 2013); and the Humanitas scheme in the Netherlands where students are given free accommodation in a care home in return for 30 hours of contact and support time per month with the residents (Jansen 2015).

In summary, there is a large focus on therapy and memory, safety and lately on offering opportunities for social connection and interaction in current non-pharmaceutical design interventions. However, there is a need for attention on the quality and meaningfulness of interaction and the role that people with dementia play within it: much social interaction occurs in everyday context, but may be missed because it is associated with functional aspects of care; also often the role of the person with dementia appears to be reactive rather than proactive because of negative emotions associated with the diagnosis of the disease.

**Designing for mindful social engagement, self-empowerment and subjective wellbeing**

To support and enhance self-empowerment and subjective wellbeing for people with dementia within and through meaningful social engagement, our approach extends design approaches to dementia, which have been discussed above, by introducing a mindfulness approach to allow for reflection, choice and responsibility to promote subjective wellbeing, self-empowerment and meaningful social engagement. This mindful design approach for application in the dementia context has been developed in detail elsewhere (Niedderer, Tournier and Coleston-Shields, under review). We therefore summarise here the key points, before moving on to the discussion of its methodological implementation in the next section.

Based on the review of existing approaches to mindful design from various contexts, we have synthesised a framework that comprises five different mindful design approaches as follows:

- **Mindful design approach 1**: Environment design may be used to improve relaxation and mood through multisensory stimulation (artificial or natural), with or without therapeutic context. For example, multi-sensorial (e.g. sight, sense of smell, taste, touch, etc.) stimulation is
typically found in gardening and through being in contact with nature, but can also be created artificially, such as in the Snoezelen (controlled multisensory environment) approach (Ozdemir and Akdemir, 2009).

- Mindful design approach 2: Design may be used to support mindfulness practices in therapeutic contexts. For example, Thieme et al (2013) have designed an interactive handheld light globe to support mindfulness practice in a mental health/depression therapy context.

- Mindful design approach 3: Design may be used as a tool to deliver mindfulness training. An example is the thought-distancing training delivered via a mobile app: “AEON allows the user to enter his/her thoughts and visualize them as written in ink on a parchment placed under water. By touching the screen, the user can interact with the water and produce waves that progressively dissolve each written thought.” (Chittaro and Vianella, 2013).

- Mindful design approach 4: Create self-awareness to initiate mindfulness practice in everyday (or therapy) contexts. A basic application of this idea can be found in the health feature in the Apple watch, which vibrates ‘tapping’ the user on the wrist every hour to alert them to stand up for a minute, or to prompt them to breathe more deeply.

Mindful design approach 5 embeds mindful choices and reflection in everyday actions and social interactions. Drawing on cognitive mindfulness, design can be used to direct awareness to other issues, unrelated of therapeutic purposes, such as social and environmental issues, cultural values and beliefs, expectations or preconceptions. It can offer the ability to activate and direct mindful awareness and reflection towards relevant issues or goals within everyday contexts through choices embedded in the design (Niedderer, 2014).

This framework of mindful design can help designers as well as people with dementias and their carers to select, develop and apply the most appropriate design interventions within dementia care and support, whether at home or in a formal care context. In order to implement the approach in our project and to develop relevant design interventions, it is further important to make the voices of people with dementia central to all steps of the process. Partners have therefore developed an interdisciplinary co-design methodology, which is discussed in the following section, which includes a discussion about co-producing with people with dementia in the research and design process, and explains the development of the different methods employed during the first and second phases of the project (data collection and design development).

**Designing for and with people with dementia**

This section discusses the design methodological implications and requirements for the inclusion of participants in the research and design process for the application of the proposed mindful design approach. It reports on the choices and rationale for the development of suitable design methods to support the data collection and to conduct the design development phase in line with the inclusive aims of the study.
Involving people with dementia: Research participation, public and patient involvement and co-production in research and design development

The MinD project seeks to develop designs based on people’s real lives and values that are relevant and appropriately designed. Involvement of users in the research and design process is therefore essential. Inclusion for the purposes of our research relates to both, participation in the traditional sense as research subjects, and as co-researchers and designers through public and patient involvement (PPI) and co-production activities throughout the project.

Traditional research participation

Traditional research participation for our purposes includes focus groups, individual interviews and diary probes. They are used to elicit issues and challenges concerning well-being and self-empowerment in everyday and social contexts from the view of the person with dementia. Their aim is to identify situations for design innovation. In this context, focus groups are used to facilitate discussion and elicit different views and arguments through dialogue (Krueger and Casey 2000) while individual semi-structured interviews offer further in-depth understandings.

These traditional participant-based research tools have been supported and complemented by two design tools: Visual cards have been developed as prompts, memory aids and discussion points for use during the interviews and are discussed further in section 3.2.1; ‘Diary probes’ have been developed as a complementary tool to focus more strongly on values and feelings, and to collect visual evidence, and they are discussed further in section 3.2.2.

Patient and public involvement (PPI)

PPI in research is defined as research carried out ‘with’ or ‘by’ members of the public rather than ‘to,’ ‘about’ or ‘for’ them (INVOLVE, 2017). PPI falls within a spectrum of public engagement from consultation to co-production and is rooted in the civil rights movements of service users and carers, best defined as ‘nothing about us without us.’ This approach closely aligns with co-design approaches (Sanders and Stappers 2008, Sanders and Westerlund 2011, Sanders, Brandt and Binder 2010), which advocate the inclusion of users into the design process, not just for consultation but for involvement from the beginning to the end. For our research, we merge these two approaches into a ‘PPI-based co-design approach’, which invites mutual decisions and actions, and aspires to a meaningful and equitable co-creation within the design process of peer researchers and stakeholders, to influence the values, process and content of the research. It thus provides the essential basis for designing outcomes that are both relevant and appropriate for the intended user group with regard to functional, emotional and ergonomic needs and wants. In other words, it aims to ensure that researchers with domain experience and design or clinical expertise and lay participants in the research work equitably, and that preconceptions on both sides are challenged; not only for example, the needs and desires of older people or people with cognitive impairment or their attitudes and capabilities regarding technologies (von Kutzleben et al., 2012) but also service user and carer ‘lived experience’ perceptions around the authority or capacity of academic ‘learned experience.’ We use PPI activities throughout the project, in parallel and interspersed with the other methods as further explained below.

In addition, peer researchers have been recruited into the exchange programme, and the values and processes of involvement activities are being documented as in this paper. In working with PPI co-researchers – while it should be recognised that everyone has needs when co-working in
meetings and workshops – the practical challenges that can arise for research engagements with people who have healthcare needs or care responsibilities require organisation to accommodate details such as:
- suitable times of day
- participant travel arrangements where possible
- appropriate and timely reminders if necessary
- flexibility and sensitivity towards health or care requirements.

Organisation by partners of MinD is facilitated by the inclusion of an experienced involvement coordinator, alongside lead involvement personnel, to plan meetings and events through ongoing consultation with both researchers with domain experience and participants with lived experience.

Designing mindful data collection tools

For the data collection, two tools have been developed to support and complement the individual and focus group interviews with people with dementia and their carers: Firstly, a set of visual cards depicting daily, leisure and social activities for use in the interviews as prompts or memory aids. Secondly, a visual diary has been developed to complement the interviews to collect visual and written information about personal values and objects used etc.

Visual Cards

The idea to use a set of visual cards (Figure 1) emerged from the discussion about the interviews and focus groups. The question was how best to communicate with participants, how to help them maintain their attention and to remember e.g. tasks and situations of daily living, during the interviews. The aim was to provide support, both, for the interviewer and interviewee during the interview through being
- usable as a prompt and memory aid;
- easy to understand because of offering a visual and written dimension.

Cards to support interviews have already been used successfully by other researchers Hassanzahl & Diefenbach (2010) and Casais, Mugge, Desmet (2016). The team reviewed existing cards as well as approaches of appropriate visualisation. This resulted in a decision to use illustration to visualise the activities in order to reduce them to the key characteristics and keep them visually simple and clear for easy recognition, following guidance for designing web-content for elderly people (Marshall, 2016). The cards were designed to cover four areas of activities and daily life in line with the mindfulness framework of the project, and the focus of the interview schedules, covering:
- activities of daily living
- leisure activities
- social activities
- wellbeing

As part of the development process, different options for the cards were presented to all members of the team as well as potential participants (through dementia outreach groups) to comment on. In this way, the cards were gradually refined in terms of the chosen activities,
figurative representations (concerning age, gender, ethnic diversity, etc.), visual readability, and other criteria.

So far the Visual Cards have been used, and their use observed, in eight interviews with people with dementia, to evaluate their role in supporting the interview process. They proved to be especially supportive as conversation starters in situations where participants did not directly know what to answer. Additionally, as a physical reminder, they helped the interviewers to cover all of the interview topics in the semi-structured interviews.

Figure 1: MinD Visual Cards, developed to support interviews with people with dementia.

Diary Probes – Do books

As a complement to the interviews and focus groups, a ‘diary’ probe set in the format of a ‘do book’ was used to obtain richer contextual information about the life of people with dementia. The ‘do book’ allowed for more active participation of people with dementia through self-documentation. Probes look at users’ personal context, including social, aesthetic and cultural environment as well as needs, feelings and attitudes (Mattelmäki, 2006).

The do books that were developed for the Mind project sought to collect data on two general topics: (1) personal information about e.g., goals, attitudes, experiences, motivation, capabilities, and social context, that could be used to develop rich personas (Figure 2), and (2) information about areas of change and needs for preservation in peoples life with respect to ADL, leisure activities, social engagement and wellbeing, in order to identify areas for design interventions (Figure 3). The design of the do books consisted of a folder and large lose leaves that could be worked on separately in the order of choice. To cater for personal preferences of participants and to generate additional visual information about their life context in addition to the verbal information from the interviews, the activities of the do books allow for various
ways of expression such as writing, drawing, photographing and crafting. Furthermore, to make the probes accessible for every one of the participants, the activities were of varying difficulty, did not require learning and were designed to be gender neutral. A few of the probes were based on the artful work of Wallace, Wright, et al. who used probes to get insight into personhood in dementia (2013).

15 do books were distributed over three countries, Germany, the Netherlands and Spain. They remained the property of the participants but anonymized pictures were taken of the results for analysis. First results promise valuable insights into decision making and attitudes with respect to future plans of people with dementia.

Figure 2: ‘Do books’ exercise about preserving important moments in people’s lives.
Developing Methods for Mindful Design Development

For the actual design development phase of the MinD project, three design methods were defined to enable the design process, which includes the scenario identification, ideation and PPI-based co-design aspects.

Mindful Scenario Task Analysis (MSTA)

Following identification of relevant intervention points from the data collection, the mindful scenario task analysis (MSTA) has the purpose of interrogating potential design opportunities to understand the various opportunities, challenges, and potential mindful strategies and solutions. It is used to analyse real-world scenarios and user stories from persons with lived experience of dementia including individuals living with dementia and care-givers. MSTA as used within MinD draws on and synthesises scenario based design (Carroll, 2000) and hierarchical task-analysis (HTA) (Rogers et al. 2011: 383) with a specific focus on mindfulness. Scenario-based analysis uses the elaboration of scenario cases to take a person centred perspective on design problems:

‘Scenarios are at once concrete and flexible, helping developers manage the fluidity of design situations. Scenarios afford multiple views of an interaction, diverse kinds and amounts of detailing, helping developers manage the many consequences entailed by any given design move.’ (Carroll, 2000:43)

HTA further helps to define individual aspects and steps within any one given scenarios, and which we have further defined for our MSTA through a focus on mindfulness values and characteristics. The mindfulness focus was developed through a test application with initial interview findings.

In the initial stages of MinD, ‘lived experience’ interviews in The Netherlands and focus groups in Germany identified some exemplars in the context of understanding potentially challenging social situations such as going out to a party, family event, group leisure activity or a meeting. (M)STA was used to break down the social going out task into its constituent components (before leaving, en route etc.) from discussion at one of the MinD exchange visits. Three aspects of the scenario were extracted and these were then further developed through UK PPI engagement: 1) Activities (mindful and non-mindful) such as planning or reflecting; 2) Mindful (and non-mindful) states such as experiencing of emotions, sensations, worries, thoughts, reactions and behavioural responses; 3) Mindful (and non-mindful) plans, tactics and strategies that are or could be employed in practice to mitigate the challenges or amplify opportunities. The initial scenario framework was tested in a patient and public involvement (PPI) group session with the addition of one further aspect, incorporated by people with lived experience: 4) Things that help or hinder in the environment or within care-giver and individual’s relationship. The generic MSTA grid is shown in Table 1 below.
Table 1: generic MSTA grid used in MinD

<table>

</tbody>
</table>

Enhanced processes of engagement during this session between researchers and people with lived experience were co-designed, introduced and evaluated in that real world scenarios detailed from people’s lived experience were collaboratively co-created and reflected on in the PPI co-production session to demonstrate the value of the approach. It was concluded that the method was useful in generating understanding, of both need and lived experience potential for involvement and co-production in meeting any such need, that is deep enough to guide requirements to feed into the design process where solutions will be sought. Significantly enhanced understandings were gained furthermore about improved collaborative working partnerships between practitioners with learned experience and people with lived experience. The method and the engagement processes will therefore be used and validated further in future co-design sessions.

**Design Brainstorming and Ideation**

To create innovative designs, the converging phase of research and data collection is followed by a diverging phase, in which – based upon relevant insights of research and data collection – out-of-the-box ideation is stimulated. The design ideation process is complementing and building on the MSTA process through targeted brainstorming of solutions for the identified scenarios based on a model provided by Panton Design. The ideation process as used for MinD is used ideally with a multidisciplinary team of preferably 5-10 participants. It should ideally include participants with creative skills, with knowledge of target groups, their needs and context as well as participants with ‘lived experience’.

The first step stars with an explanation of the basic rules of the creative sessions, which are: 1) criticism isn’t allowed as it blocks creativity, 2) every participant should try to come up with as many ideas as possible because usually it requires a large quantity of ideas to find that one innovative, outstanding idea and 3) copying from other participants is allowed because someone's ideas can inspire others to come up with even better solutions.
The second step is to define the goals of the creative session and sharing the relevant insights from research and data collection. In the first MinD design workshop, the insights used were four major issues in the context of dementia: a) delivering the diagnosis, b) acceptance (internal and external), c) changing relationship and d) living in a familiar world. In small teams of two participants each of these four issues were explored further by sharing knowledge. Conclusions were noted and shared.

Figure 4: Sharing and discussing brainstorming ideas.

In the third step each team described what the situation would be in a semi-perfect world, in which dementia would still exist, but all imaginable technology and services would be at hand and free. Based upon these descriptions many ideas were created in the fourth step by all participants, both individually and after consulting other participants. In the fifth step each participant detailed his or her top 3 ideas. In the sixth and final step each participant contributed to all top ideas.

So far this process has been used in one ‘test’ workshop to familiarise all researchers with the process and understand its rules and potential. The process will be used in the forthcoming design development phase.

**PPI-based mindful co-design**

The MinD project involves people with lived experience of a memory problem including people with a diagnosis of dementia, informal caregivers who are often family relations of a person with dementia, and people with wider lived experience of a mental health condition or a caring role. PPI and co-production are used throughout the project and are arranged through several partners of the consortium, including Alzheimer Europe in Luxembourg and Nottinghamshire Healthcare NHS Foundation Trust (NHT) in the UK.
NHT has for example commissioned a peer researcher as a fee-paid participant with lived experience, along with a team of volunteers recruited based on aptitude and interest, and whose expenses are fully reimbursed. Alzheimer Europe organised a PPI consultation with the members of the European Working Group of People with Dementia (EWGPWD) in Luxembourg on 15 May 2017, at which the MinD researchers presented their findings so far and obtained feedback about issues related to the ongoing development of the project.

Specific examples of PPI co-production in MinD so far include:

- Feedback on the development of design tools such as the visual cards;
- Ideas generation about mindfulness aspects of design, for example, of clothing and accessories prior to one of the project meetings;
- Scenario co-production workshop;
- Feedback on and input into project development and methodology.

Further involvement in the design process will include involvement in the ideation and design development processes over the next year based on the parameters set out in this paper.

**Conclusion**

In summary, this paper has described the foundations and methodology adopted in the MinD project for designing with and for people with dementia.

The first part of the paper has offered a brief review of the premises of the work in terms of challenges for people with dementia with regard to issues of subjective wellbeing, self-empowerment and social engagement, and available design support. It has introduced and proposed the use of the concept of mindfulness and shown the different possibilities of using design to embed mindfulness both in therapy and everyday contexts. This means our approach looks at opportunities and people’s capabilities and flourishing, rather than a deficit oriented approach discussed above.

The second part of the paper has co-developed the design methodology including traditional participant and PPI co-production for the different stages and aspects of the project, and their role and requirements in the process. It has further considered the different design methods for user-centred working, including Mindful Scenario Task Analysis, Design Ideation, and a framework for PPI-based co-design activities.

The contribution and benefit of the proposed framework and methods is in offering a transparent and evidence-based approach and guidance to working proactively with people with early to mid-stage dementia (and their carers) on design research projects to develop real-life interventions that are based on the wishes, wants and needs of people with dementia and their carers.

**Kristina Niedderer, University of Wolverhampton**

Dr Niedderer, PhD, is Professor of Design and Craft at the University of Wolverhampton. Niedderer’s research focuses on the role of mindfulness and emotions as a means to engender mindful interaction and behaviour change through design. She leads the European project ‘MinD’ - Designing for people with Dementia: designing for mindful self-empowerment and social engagement, Grant No 691001.

**Isabelle Tournier, Luxembourg University**

Dr. Isabelle Tournier, PhD, works as a Postdoctoral Researcher in Gerontology and Psychology within the Research Unit INSIDE (University of Luxembourg, Luxembourg). Her main research interests are well-being, cognitive adaptation and self-regulations, safety, mobility, and routines in older adults.
Dons Coleston-Shields, Nottinghamshire Healthcare NHS Foundation Trust

Dr Coleston–Shields, PhD, is Principal Research Fellow, Consultant Clinical Psychologist & Neuropsychologist at the Institute of Mental Health at the University of Nottingham. She currently manages a large, multi-project research programme concerned with service provision for crisis in dementia in the UK. Wider interests include promoting therapeutic inpatient environments and carer support.

Michael Craven, Nottinghamshire Healthcare NHS Foundation Trust

Dr. Michael Craven, PhD, Senior Research Fellow, has over 25 years of experience in technology design and evaluation, currently focussed on healthcare technologies at NIHR MindTech Healthcare Technology Co-operative, connected to Nottinghamshire Healthcare NHS Foundation Trust and the Bioengineering research group in the Faculty of Engineering at the University of Nottingham.

Julie Gosling, Nottinghamshire Healthcare NHS Foundation Trust

Dr. Julie Gosling, PhD, is associated with the University of Nottingham, School of Health Sciences and the Institute of Mental Health (Training Education Research Lead, OPEN FUTURES IRG Research Lead. Dr Gosling identifies herself as an older woman with lived experience of mental distress, and who cared for 16 years for a woman of her own age with dementia. Her research specialisms are co-production with marginalised voices, and narrative frameworks.

Julia A. Garde, University of Twente

Dr. Julia Garde, PhD, is assistant professor at the University of Twente, Julia develops co-design tools to bring together stakeholders in healthcare projects. By applying design games in various cases and scales, digital and analogue, she learns about co-operation of people with different backgrounds and develops solutions that contribute to improving healthcare.

Ben Salter, University of Wolverhampton

Benjamin Salter, MA, is Senior Lecturer and Course Leader for BDes (Hons) Interior Design at the University of Wolverhampton. His interest in the built environment focuses on residential and temporary design, with an emphasis on the integration of digital technologies, and cutting edge material practices.

Michaelle Bosse, Technische Universität Dresden

Michaelle Bosse, MA, has researched into design and sustainability since 2003. In 2007, she graduated in Product Design from UFPR, Brazil, and in 2013, she completed her Masters on usability for elderly people at UDESC, Brazil. Currently, she is studying for PhD at the Technische Universität Dresden, Germany, focusing on Mindful Design.
Ingeborg Griffioen, Panton Healthcare Design

Ingeborg Griffioen is PhD student and Design United Visiting Professor at Delft University of Technology and founder and owner of Panton, a design agency dedicated to creating innovations for healthcare. She is also one of the initiators of the VVCZ, the national association of hospitals co-operating to improve patient safety.
Understanding passengers’ experiences of train journeys to inform the design of technological innovations

Abstract

In this paper, we present results from a collaborative research between academic institutions and industry partners in the UK, which aimed to understand the experience of rail passengers and to identify how the design of technology can improve this experience. Travelling by train can often provide passengers with negative experiences. New technologies give the opportunity to design new interactions that support the creation of positive experiences, but the design should be based on solid understanding of user and their needs. We conducted in-depth, face-to-face semi-structured interviews and used additional questionnaires given to passengers on board of trains to collect the data presented on this paper. A customer journey map was produced to illustrate the passengers’ experiences at diverse touchpoints with the rail system. The positive and negative aspects of each touchpoint are plotted over the course of a ‘typical’ journey, followed by the explanations for these ratings. Results indicate how the design of technological innovations can enhance the passenger experience, especially at the problematic touchpoints, e.g. when collecting tickets, navigating to the platform, boarding the train and finding a seat. We finalise this paper pointing towards requirements for future technological innovations to improve the passenger experience.

Keywords: customer journey map; user experience; user centred design; interaction design; rail transport; innovation

Sometimes passengers have negative experiences when travelling by train (Wockatz & Schartau, 2015). There are diverse aspects of the rail transport that could be improved (Transport Focus 2015) and experiences tend to worsen with the increasing demand to the rail system (Office of Rail and Road, 2015a, 2015b). Customer journey experience maps are commonly used to understand and visualise user experience (Jüttner, Schaffner, Windler, & Maklan, 2013), with examples picturing passenger’s interactions with transport systems (Aceves-González, 2014). The information provided by journey maps can be used to improve service operations (Tseng, Qinhai, & Su, 1999). There is potential for technology to be designed in a way that support positive experiences (Desmet & Hassenzahl, 2012).
This research aggregates existing knowledge and complements it with bespoke data collection to understand the interaction between passengers and the rail system. The aim was to understand how rail passengers currently experience their journeys, providing real-life insights on interactions with the system, from planning and buying to alighting at the final station, in order to identify how innovative technologies can improve this experience. The study design focused specifically on the points of interaction where technology can affect the user experience. A passenger journey experience map was produced in order to illustrate how customers feel at each of these main touchpoints with the system, highlighting particularly where technology can play a role in improving the customer experience. The map is complemented by analysis of the interactions and suggestions for the development of technology to enhance customer experience for rail travellers.

This work is part of a consortium formed by two academic institutions and four industry partners named CLoSeR. The collaborative nature of this research requires synergy between academia and external organisations, combining research methods to better inform the production of innovation that could improve user experiences. The main phases of the project are being conducted over a 27-month period, from December 2015 to March 2018.

**Literature Review**

British rail transport is observing an increase in demand in recent years, with noticeable growth in the number of journeys, kilometres travelled and passengers entering, exiting and changing at stations (Office of Rail and Road, 2015a, 2015b). The extra demand places additional strain on a system, which inevitably will negatively affect how passengers perceive the quality of the service. User experience (UX) in public transport is subject to growing interest from the public sector, academia and industry. A recent government report indicated the need to increase the public transport UX as one of the solutions to promote efficient and sustainable transport systems that meet the needs of travellers in the UK (Wockatz & Schartau, 2015). Their results show that passengers complain about “lack of personal space, lack of connectivity, and a perception of poor value for money” (Wockatz & Schartau, 2015, p. 29). Academic research has been evaluating user experience and satisfaction with travel through diverse methods, from large-scale surveys (Ettema et al., 2011) to individual depictions of travel experiences (Jain & Lyons, 2008). A yearly survey with passengers in the UK provides a wide picture of customers’ satisfaction with rail travel (Transport Focus, 2015). Train operation companies and associations also evaluate passenger’s experiences via focus groups and customer journey mapping (FGW, 2016 – personal communication, ATOC 2016 – personal communication).

Experience can be defined as an episode or a length of time that one individual go through (Hassenzahl, 2010), involving tangible perceptions through our senses and also feelings and thoughts. UX it is a very personal phenomenon: what engages and enchants one user may bore or irritate another (Blythe, Reid, Wright, & Geelhoed, 2006). Interactive products and services that we encounter in our lives have the power to shape what we feel, and will inevitably influence our experience (Hassenzahl & Tractinsky, 2006).

One common way to understand and visualise UX is through the design of Customer Journey
Maps, which are graphical representations of one’s encounters with the products, services or systems. Diverse types of service providers use customer journey maps to understand and improve their operations (Johnston & Kong, 2011; Tseng et al., 1999), including studies about transport services mapping the experience of passengers (Aceves-González, 2014; Aceves-González, May, & Cook, 2016). These diagrams usually contain different stages of the journey, user actions and emotions (Williamson, 2016). The map displays the ‘touchpoints’ for each main point of contact between the user and the system, where some sort of interaction took place. The development of the touchpoints usually derive from the definition of the sequential incidents of the interaction (Jüttner et al., 2013). The process for designing such maps involves collecting qualitative data, usually through interviews, where participants report the significant occurrences and issues during the interaction with the product, service or system (Stein & Ramaseshan, 2016). Interview transcripts are then subject to a thematic analysis (Braun & Clarke, 2006), and these themes inform the elements that define the touchpoints in question. It is also possible to obtain opinions from participants using questionnaires handed to the target population. This method is frequently used to understand who the users of a system are and what views they hold (Goodman, Kuniavsky, & Moed, 2012).

We will describe in the next sections the methods used and the results obtained during this study, which provide a detailed account of the experiences of rail passengers. We present the customer journey experience map and then discuss the implications of these results. The conclusions indicate the requirements for technological systems and suggest opportunities for improving experiences in each of the selected touchpoints with the rail system.

**Methodology**

Two methods of data collection were used to generate the journey maps: face-to-face semi-structured interviews and paper questionnaires handed to passengers. Full ethical approval was granted by the Biomedical & Scientific Research Ethics Committee (BSREC), from the University of Warwick. The recruitment of passengers for interviews happened through emails sent to employees of the Warwick Manufacturing Group. Those who had taken trains recently were invited to take part in an interview having a variety of open-ended questions to describe their train journeys and express their opinions. Participation was completely voluntary: employees were under no obligation to take part in this research, and no penalties nor financial incentives were given to motivate participation. A further data collection method used printed questionnaires handed to passengers on board of trains. This instrument used similar questions to the face-to-face interview adapted to the printed format. Table 1 shows participants and data points from the instruments used during this research: interviews and questionnaires. Both data sources were merged to provide a concise analysis across all the 951 statements extracted from participants’ expressions of opinions.

### Interviews

Face-to-face semi-structured interviews with 20 passengers were performed to understand their expression of attitudes, feelings, preferences, needs, behaviours etc. in relation to rail travel. Interviews are the most frequent method used for understanding user experience. “Observation is critical, but to really know the user’s experience, you have to ask him or her about it, and that’s an interview” (Goodman et al., 2012, p. 129). The initial part of the questionnaire used for this study had questions about the main touchpoints with real services, namely: planning and buying; ticket collection; wayfinding; boarding; seat location; ticket validation; and alighting. These touchpoints were selected after a review of existing customer journey maps and analysis of where technology can influence the experience. Participants were prompted to describe these activities, for example explaining how they usually do it, what works well and not, and how would they improve that touchpoint.

![Figure 1 – Touchpoint experience rating exercise](image)

In order to motivate participants to recall their train journeys and to foster discussions, they
were asked to rate their experience on a 5-point ‘smiley scale’ from very happy to very sad, for the seven touchpoints. The interviewer then disclosed the nature of the technological innovation proposed by the CLoSeR project. Participants were asked to rate their experiences again, but now as if the CLoSeR system was implemented. Finally, a set of questions, similar to the first part of the interview, were placed in order to obtain participants’ impressions related to these innovative systems.

A total of 8 hours and 47 minutes were spent interviewing the 20 participants, meaning an average of 27 minutes per interviewee. The interviews were all recorded with the interviewee’s permission, transcribed verbatim and imported into QSR International NVivo software. This data was subject to customary thematic analysis (Braun & Clarke, 2006) to facilitate the process of creating meaning from the qualitative data.

**Questionnaires**

Questionnaires were used during this research in order to increase the reliability of the results and to validate the information obtained from the interviews. Passengers on board of weekday, off-peak Great Western Railway (GWR) services were randomly approached and invited to fill in printed questionnaires and to agree to contribute via a consent form. The researcher would come back a few minutes later to collect the questionnaires. Passengers’ responses were transcribed into the same NVivo file used for the interviews to complement the existing thematic analysis.

**Results**

The information obtained from the interviews and questionnaires were aggregated in order to understand passenger’s opinions and feelings in relation to their journeys. This knowledge indicated the touchpoints with the system to be plotted on a map and the corresponding mood on a ‘smiley scale’. The Passenger Journey Experience Map, which resulted from this research, can be seen on Figure 2. The design follows recommendations from practitioners on how to plot this information on a map (Williamson, 2016). On the top of the map we define who is represented on the map and who contributed to the information there displayed. The second box of text indicates the scenario to which the experience is plotted (Oliveira, Maguire, Mitchell, & May, 2015). The user goals are indicated on the right hand side of the map, and this information is linked to the classification of touchpoints at the bottom of the map. The colour bars correspond to the main user goals in each stage of the journey. The bottommost row (in blue) indicates the business goal that the map supports, describing that there are opportunities for the CLoSeR project to improve experiences on those specific touchpoints.

**Passenger journey experience map**

The process of planning journeys and buying tickets is usually positive for passengers. That is because there are diverse alternatives to suit individual preferences. Participants reported that they purchase tickets on the web on their preferred vendor, using their favourite apps on smartphones. However, five participants indicated that they still prefer to buy tickets at the
station from a real person. Passengers gave diverse explanations for using their preferred purchase methods, such as that ticket machines do not give you the best prices or all the options, that online is cheaper, or that they prefer the assistance of a staff member. It indicates that there may be resistance to using a different method than usual. Also, some participants mentioned having different methods for different journeys according to price and convenience:

P5: I usually I do it online. Or at the station. If I go to London or whatever I'll do it online, but I go to Oxford regularly so I buy it at the station.

The arrival at the station is usually positive for passengers, if they have enough time, can relax and have a drink. However, if they are late, it will affect the next steps on the journey and make the experience particularly negative. Most passengers choose to collect their tickets at the station before departure. This stage is often negative for passengers since there are sometimes queues and it is a time-consuming process per se. In addition, there is the effort of inserting the card and inputting the code, which is seen as unnecessary.

P20: you have to use that debit card to print the ticket off which is quite annoying.

P13: Some of the older machines do take an eternity to print the tickets, and if you’re standing there with 5 minutes and you’ve got tickets gradually printing... it’s frustrating.

Once with the tickets at hand and with time, the wait for boarding can be fine. However, in large stations and at busy times the concourse can become crowded with people staring at the boards waiting for the authorisation of boarding and announcement of the platform. Passengers report that sometimes there are too many people or this information comes too close to the departure and there is competition, making the experience very negative.

P2: Euston is a bit of a pain, because typically the boards don't update for trains up to Manchester up until about 5 or 10 minutes before the train is about to depart which normally means there is a mad dash for the gate. And you end up with a scrum of people all trying to board the same train in a very short period of time.

P13: One annoying thing is the train is at the platform, but you aren’t told until 5 minutes beforehand that you should go, and there’s a swarming.

The need to go through the barriers can worsen the experience, they not always know which ticket to insert, and there may be a bottleneck. However, passengers acknowledge that it is unavoidable. Thanks to the barriers, the stations are safer, and it is fair with those who paid since it prevents fare evasion.

P3: Ticket barriers are always annoying.

P5: It just seems to create a lot of unnecessary queueing. I mean I understand why they do it, because people don’t buy tickets.

The wayfinding process, when passengers have to go to the platform, is ranked rather negative by participants at large stations, due to big crowds, poor signage or lack of time. However, in small or familiar stations that does not seem to represent a problem.
P3: If you’re transferring trains, because I never know what platform, so I have to get off and look for a board and so.

P4: I’m probably a little bit late when I arrive and it can sometimes be a bit difficult to find a platform.

**Boarding the train** is often problematic due to the insecurity of knowing if that is the right train. Some trains do not have any indication of the destination outside or inside, and if they do, it may not be very visible. The step and the gap are frequent concerns. It is also difficult to know where the coach for your specific seat reservation will be at the platform. Big crowds and other passengers’ aggressive behaviours compound the problems, making the experience during this stage of a journey rather negative.

P15: Wayfinding is a nightmare, I took the wrong train just days ago.

P17: I used to get the ten past 8, it was absolutely horrendous. Like fully elbowing people to get in. It’s horrendous, and dangerous.

P18: Where I really struggle at a different station is where you should stand at the platform. So if you’ve booked a seat, where should you be standing so you don’t have to run up the platform when the train arrives.

Once on board, and being able to **find a seat**, the passengers’ experience improves considerably. They are now heading to their destination, can occupy their personal spaces and engage in their preferred activates. However, if on a crowded train and unable to find a seat, frustration builds up, especially for those paying large sums for their tickets. Participants mentioned a number of issues with the current system for seat reservations. For example, that sometimes the allocated seat is not exactly what was selected during booking.

P13: When you’re booking online and you specify your seat, they deliberately set out to troll you, you say forward facing window seat, and that’s interpreted as sitting backwards or next to a wall.

Often the reserved seat is difficult to find because there is no clear indication of where the coaches will be when the train arrives at the platform. In addition, some passengers do not use their reservations and decide to sit elsewhere resulting in one passenger occupying virtually two seats.

P3: I never bothered trying to find my seat because I’d just get on the nearest coach to me, that’s fine, as long as there’s space. But I won’t go and hunt down where that seat is. I just seat in whatever seat I can find, even if I do have a seat reserved.

One issue that can affect the journey rating is if someone is sat in someone else’s reserved seat. The resulting conflict (or the need to ignore it to avoid conflict) compromises enormously the travel experience.

Probably the larger chunk of time of the journey is the **travel** itself. That can be a positive experience if passengers find themselves in a stress-free environment where they can read, work, interact or simply pass the time. A crowded train or the behaviour of other passengers can compromise this experience though.
At certain points of the journey, passengers are generally asked to present their tickets for validation. This process is often positive, since it is probably the only chance of interaction with the train manager. Passengers then have the chance to ask questions and get the valuable reassurance they need. This occasion is also positive because it is when passengers see the figure of authority on board, which can bring feelings of safety and security. Knowing that someone will come to check tickets makes them feel better that other people are not travelling for free, or in the event of conflicts such as seat disputes. The negative aspects of the ticket validation process are the fact that sometimes passenger have several tickets with them and it’s difficult to find them or know which one should them hand for inspection.

P9: Sometimes you get about 4 different tickets, and then it can take you ages to find the one they want to see.
P1: By checking tickets it’s giving them a reason to be going up the train and interacting with people. If somebody’s got a problem, they stop and talk to them.
P8: Checking the ticket doesn’t really inconvenience me to be honest. It almost in a way gives some reassurance that if you’re travelling without a ticket you will be caught.
P13: I do remember when I had a small book’s worth of tickets, and a particularly jolly inspector, he just took one look at all those tickets and said ‘oh someone has been using a lot of trains’ (laughs). The guy, somehow, despite working on a dismal morning, my goodness, he was just so friendly.

The process of alighting at the destination presents some anxiety, especially in busy services. Passengers report having to wait behind other people, and the fact that there are only two doors at each end of a coach, which creates the risk of missing the stop. Passengers then find the exit and leave the station, which are usually trouble-free activities, probably because people may not be in a hurry as they are when arriving at the station. The fact that they have to go through the barriers again is seen as troublesome if they have to locate the right ticket to leave the station, and as redundancy if they have been checked already at the entrance and on the train.

P5: What I don’t understand though is why do you have to go through the barriers anyway, if you’ve already had it stamped. It’s like a double check.

Discussion

The results presented here illustrate how passengers currently experience their train travels. Even though there have been other studies on passenger experience and other passenger journey maps produced, this research contributes to the existing knowledge by focusing on specific touchpoints, which were not explored in detail previously. These touchpoints are the ones where technology is believed to have higher potential to enhance the rail experience, specifically when passengers have to collect their tickets, go through the barriers, find the platform, board the train, find a seat and present the ticket for inspection. This paper also adds to the previous literature by proposing a number of strategies of how technology can create better experiences for rail travellers.
As illustrated by the passenger journey experience mapping (Figure 2), passengers have a range of positive and negative experiences during rail travel. Depending on the scenario, a passenger can be pleased by how their activities panned out during the interaction with the systems, but in other situations, the interactions may seem negative hindering the experience. Systems and products should always be designed with the aim to provide a good UX, and interactions should be worthwhile and valuable (Hassenzahl, 2010). It is possible to design for pleasurable interactions (Desmet & Hassenzahl, 2012) and mapping of passenger experiences provides interesting insights into how technology could provide better experiences.

**Touchpoints**

Planning and buying tickets is usually a positive experience, given that currently there are several channels where tickets can be bought according to passengers’ preferences. Every channel presents advantages and disadvantages depending on the type of passenger and scenario. Even though the proportion of sales at the staffed ticket offices is decreasing year by year, it still remains as the most popular method of purchasing tickets, representing about 40% of the sales in 2014 (Transport Focus, 2016). With the addition of new technologies, the variety of purchase alternatives should ideally be maintained. An attempt to force users to use one specific channel to buy tickets may hinder the user experience.

The ticket collection is frequently seen as a negative experience as it takes time and effort. Our results resonate findings from a usability study which indicated that the ticket vending machines are complicated, unclear and passengers were not confident they would find the best price (Transport Focus, 2010). Passengers were pleased with the idea of removing the need to interact with these machines altogether. The experience can be improved if passengers have an easy way to prove that they have the right to travel. Technology can provide means to identify passengers and allow access to stations without the need for a paper ticket printed prior to boarding.

However, some passengers are still reluctant to use smartphones. A new system should provide means of identification of passengers who do not own a smartphone, or in the case of batteries running flat, or simply not carrying their devices at that time.

The process of waiting for the train can be pleasurable if passengers have time to spare, if they know the station in question and if it is not very crowded. However, passengers reported that at larger stations at busy times the experience can be really miserable. If a system can provide platform numbers directly to smartphones as soon as they are available, it can reduce the anxiety and the need for passengers to congregate at the main concourse at busy stations, reduce the need to stare at the boards and minimise the chances of a ‘mad rush’ to the train.

Another problematic touchpoint is the interaction with the ticket barriers. Passengers usually do not know which ticket to use, it can delay the process of going to the platform, and is worsened by queues at peak time. A system should provide a way of going through the barriers quickly and with less effort. The idea of removing the barriers altogether is not welcomed by passengers, which rely on them to have a safer station and reduce fare evasion.
A frequent complaint from passengers was regarding the boarding process. There is insecurity about if ‘this is the right train’, difficulty getting to their reserved seat or to locate an empty seat. If an application gives more information for passengers, it can minimise the insecurities during the boarding process. Previous research shows that passengers generally stand in the central portion of platforms and it eventually causes the ‘concentrated boarding’ (Fox, Oliveira, Kirkwood, & Cain, 2017). Our study shows that they would like to know where is the best place to stand at a platform to reach their reserved seats. Often there is no indication as to where the train will stop, how long it is or where first class coaches will be. In general, the provision of detailed information was highly valued by participants, in accordance to previous reports (Transport Focus, 2014). A system can communicate directly to mobile devices to enhance the information accessibility for passengers and create customized travel experiences (Miñano et al., 2017). It can for example present a map of the train with number of coaches and sequence, real time occupancy of seats and location of a reservation, so passengers can anticipate how to get to their seats.

On board of the train, the most negative aspect was in relation to seat location. A large number of passengers are not guaranteed a seat since they do not have a reservation. Those are season ticket holders, passengers on open return tickets and those buying tickets close to the departure of the train. Passengers would strongly appreciate a technological innovation that allows them to find seats. For those with reservations, sometimes the current system allocates a seat which passengers do not like. Passengers place different values to different seats (Wardman & Murphy, 2015). A reservation system that allows passengers to select a specific seat according to their preferences, or change an existing reservation, can improve the travel experience.

A dynamic seat reservation system will not prevent overcrowded trains and the fact that someone may sit on a reserved seat regardless. Often passengers do not have a choice given rush hour, disruptions or cancelations. However, some passengers have flexibility and are willing to wait for a later and less crowded train or to board a less crowded carriage (RSSB, 2016). A system should be able to show occupancy levels of next trains in real time, giving passengers the possibility of making informed choices.

The main issue with the ticket validation process is with the ticket itself. If a system allows people to validate their right to travel without the need of a physical evidence, it can save the trouble of having to locate tickets, find the right one, and produce it to crew. However, passengers value highly the fact that an inspector can come and interact with them. Similarly to a previous research, our results show that the presence and assistance provided by a customer-facing staff is still seen to be essential, such as for ticket retailing, accessibility, information provision, assistance and personal security (Transport Focus, 2016). However, if a system automates some of the activities performed by crew, especially the mechanical work of checking tickets, there will be more time available for them to give personalised service and customer care for those in need.

Alighting is not often a reason for concern, although on busy services or unknown routes there is anxiety in relation to the right stop. If an application gives the information about when to proceed to the doors, that can reduce the anxiety of alighting at the right station. When leaving the station, passengers mentioned the need to go through the barriers again, as it affects the
experience negatively. Passengers will appreciate if a technological innovation makes it easier and more convenient than paper tickets to enter or exit a station.

Conclusions

This research used customer journey maps as a method of understanding passengers’ experiences in relation to rail travel. With this research, it was possible to produce knowledge about passenger journey experiences and complement existing literature in user experience for the travelling public. This research focused in matching this new knowledge with the possibility of introducing new technologies to improve passengers’ journey experiences at specific touchpoints with the rail system. A number of conclusions are drawn from this research and listed below. From the interviews and questionnaires, it was observed that passengers have specific high-level goals when using train services. This section highlights these goals indicating the potential for improving experiences with the introduction of innovative systems for the rail industry.

- Passengers want a better way of proving the right to travel – Collecting tickets is ranked as negative due to the time and effort involved. Technology can grant access to only the right person without the need for a physical ticket.
- Passengers want to have a stress-free navigation through stations up to their seats on a train – A system can give personalised information to passengers according to their preferences, destinations and familiarity with the route. Push notifications can ensure passengers receive the information as soon as it is available.
- Passengers want to find a seat – Seat sensors can provide information to show occupancy levels, free seat availability and location in real time. Reservations can be issued in real time.
- Passengers want an easier way to locate their reserved seats – Visual representations of trains and coaches and their respective positions when the train arrives at the platform can help passengers anticipate and plan how to get to their seats.
- Passengers have their own preferences regarding seat choices – A dynamic system should allow changes to reservations in real time.
- Passengers do not appreciate having to travel on crowded trains – Technology can inform occupancy levels of next trains in real time, helping passengers’ decision-making process in search for less busy train.
- Passengers appreciate the physical presence of a crew member – There is still the need for on-board authority for safety reasons, or in order to give information about the journey. A system can automate some of the repetitive activities performed by crew such as the process of validating tickets. With more time available, train crew can give personalised service and customer care for passengers in need.

This knowledge is being shared and discussed with all consortium members. The academic institutions and industry partners are working in cooperation to develop these innovative technologies which have the potential to ultimately benefit the travelling public.
Acknowledgements

This research is performed as part of the “CLoSeR: Customer Loyalty and Dynamic Seat Reservation System” project, funded by RSSB / Innovate UK (Grant No 102483). This project was selected through the competition ‘Enhancing Customer Experience in Rail’. Partners in this project are the University of Warwick, Cranfield University and four industry partners: Unipart Rail, TrainFX, Loyalty Prime and Great Western Railway.

Author biographies

Luis Oliveira
Luis is a Research Fellow at the University of Warwick. He is involved with the CLoSeR project, funded by Innovate UK through their Enhancing Customer Experience in Rail competition. Luis focuses on the user-centred design and user experience, and is responsible for conducting all stages of the user research, from designing the studies to analysing data and reporting the results. Luis obtained his PhD from Loughborough University as part of the User-Centred Design and Sustainable Design research groups. He developed new ways for motivating behaviour change to promote sustainable energy consumption, applying user-centred design methods to investigate how technology can work as the platform for change.

Callum Bradley
Callum Bradley has a BA (Hons) degree in Philosophy and Literature obtained from University of Warwick in 2017. As a research intern on this project, he has underlined the recognition of and borrowing from a wide array of theoretical concerns that originate from training across the social sciences and humanities. Presently commencing an MA in Psychoanalytic Studies, Callum's interest as to the diverse ways in which people can be understood and considered in the world has had influence on both initial strategies of gathering data, as well as creative techniques for re-imagining the presentation of customer journey maps.

Stewart Birrell
Stewart A. Birrell has a BSc (Hons) degree in Sport Science from the University of Hertfordshire and a PhD in Ergonomics from Loughborough University. His primary research interests concern how humans interact with their surroundings and subsequent effect on task outcome and performance, which has been developed through working within a variety of different domains such as sport, military and transport. Stewart has recent experience in the design and evaluation of in-vehicle systems, where currently he works as an Assistant Professor at University of Warwick investigating human factors aspects of low carbon transport. Stewart has numerous scientific papers published in the field of Human Factors.

Andy Davies
Andy is the Research Manager from Unipart Rail involved with this project. He is a purchasing professional with an Engineering background and over twenty years procurement experience of a wide range of quality component and bespoke manufactured products for both high volume automotive and SME manufacturing/distribution companies. He has considerable experience of Global sourcing particularly from China and the Far East and with a proven record of accomplishment of purchasing quality electronic and mechanical products in order to achieve significant cost savings.
Neil Tinworth
Neil is the Research and Innovation Director at Unipart Rail. He has over twenty years of international business experience, undertaking strategic planning and analyses, organisational restructuring, business and process analysis, compliance and risk management, and organisational change and development in international business environments within management consultancies, industrial companies and operating leasing organisations.

Rebecca Cain
Rebecca Cain has a background in design, with a First Class degree in Industrial Design & Technology and PhD in user involvement in the design process, both from Loughborough University. In 2009, she was awarded a prestigious EPSRC Challenging Engineering fellowship to build new research capability in improving the design of healthcare environments through user involvement in the design process. Rebecca's innovative multi-disciplinary research programme 'Participation in Healthcare Environment Engineering' brought together design and engineering, with architecture, psychology, healthcare and ICT, and involved working in close partnership with the NHS, patients, architects, designers and engineers. Her research has created improvements to the healthcare environment in areas such as the Emergency Department, the hospital soundscape, wellbeing centres and waiting rooms.
Mapping for Mindsets of Possibility
During Home Downsizing
Lisa Otto, Carnegie Mellon University, Pittsburgh, PA, USA, eotto@alumni.andrew.cmu

Abstract

How can design orient people to an expanded sense of future possibility? Design researchers are beginning to recognize design’s potential role not solely in producing products, services and strategies but, instead, in shifting mindsets and behaviors. This shift requires a different view of the design practice, from engaging users to gather insights to be implemented, to that process as the actual material of the design. Borrowing from the framework of practice-oriented design, a first step in these processes is expanding participants’ understanding of future possibilities. In opening future possibilities, one recognizes an expanded range of futures and, ideally, engages in dialog with other people and their range of possibilities. This paper introduces mapping activities that are intended to reframe participants’ perception of possible futures. This study conducted pilot workshops with participants who were downsizing their home and struggling with decisions about their things and spaces. This paper argues that working with people already engaged in life transitions such as downsizing presents a rich opportunity for these futuring methods, as they are already beginning to grapple with designing for possible futures. These methods provide a stake in the ground for future exploration of potential methods to engender mindsets of possibility and engage in trialing methods like living labs.

collaborative design, practice-orientated design, mapping, design process, futures

If the work of design is to build futures, then the work for designers is not only to build these futures independently but to engage the public in constructing these futures. This role of designer-as-facilitator creates new tasks for the designer and requires a new understanding of the role of design research. The designer must not simply use participation of the public to gather insights to implement a final product, service or strategy, but must expand people’s concept of future possibilities. Much of the time, decision-making involves unconsidered assumptions about the present state and expectation that current trajectories will persist. In opening future possibilities, one recognizes an expanded range of futures and, ideally, engages in dialog with other people and their range of possibilities.

This ability to open discussion and potential in participants has long been a latent component of exploratory design research methodology. Recently, with methods like living labs and practice-oriented workshops, designers have begun to acknowledge that the artifacts of design can be a means to an end rather than an end in themselves. This reconceptualization of design recognizes the dynamic nature of people’s practices and routines and the role of design artifacts in enacting change in them. In “Living the (Co-Design) Lab,” (Binder et al., 2011, p. 3) the researchers find that “design games thus became the nexus that made the design laboratory cross over from user research to design exploration. The games had a similarity to affinity diagrams and other diagramming methods usually associated with the analysis of field material.” Here the subjects become the researchers working to understand and shape their own lives. In this framing, the designer’s new role is to create environments for transitioning to new practices. Workshops that once were intended to gather information are now reframed as spaces to create shifts in
understanding and practice.

Designers taking up social practice theory or exploring living labs typically attempt to encourage transition from one practice to another. However, people already engaging in life transitions, such as downsizing their home, present a rich opportunity for designers to support this type of futuring. Downsizers are already beginning to contemplate futures, though this may be limited in scope. Having recently left (or considering leaving) the workforce and with homes newly empty of children while looking out to future health changes, downsizers are considering how they can match their surroundings to their changing selves. With more than 25% of the over-50 population making at least one housing transition and those below the age of 75 moving the most (Painter & Lee, 2009), this is a particularly rich moment to explore as a case study.

A key part of this new reframing is opening up participants to have a more expansive view of future possibilities. Mapping exercises are often used by designers to gather and understand their participants’ values. But such exercises also have the potential to do this work of expanding futures. Using the case of several mapping workshops with people who were downsizing their home, I will demonstrate the potential for design methods to open up participants to an expanded range of future possibilities.

**Literature Review**

**Approach**

The conventional design process still maintains a division between the end user, research participant and the designer (Kjærgaard & Otto, 2012). In participatory design, though the methods “utilize the skill-based but often tacit knowledge of users about their own (work) practices directly in the design process in order to create more appropriate and democratic technological solutions for the user,” the designer will still synthesize these findings independently (Kjærgaard & Otto, 2012, p. 79). Under these frameworks, participants are engaged in the research process, but only in that they will provide information and insights for the designer to incorporate into a final design, service or strategy. However, designers have begun to acknowledge that design can play a role in creating shifts in perception and routine which itself can be the outcome of a design process.

Shove (2007), a founder of practice-oriented design, describes how, in the shift from product-oriented design to human-centered design, the understanding of values is reconceived. She writes, “rather than a design(er) led process in which products are imbued with values for consumers to discover and respond to, proponents of this more radical form of user-centred design argue that traffic flows both ways” (Shove, 2007, p. 133). In practice-oriented design this is taken a step further. User needs are not innate and discoverable through design research but instead are formed as one engages in a routine or practice (Scott, 2011). In this reframing, engaging in a design workshop shapes one’s needs as much as it reveals one’s needs.

The desired outcome for the process moves from a product, service, or strategy to a shift in practice. For example, designers who have begun to explore the implications of practice-oriented design with an eye toward sustainability often have reduced water consumption as their desired outcome (Scott et al., 2011; Kuijer, 2014). Because the outcome is not a product, service, or strategy, but rather a change of practice or routine, workshops that would have been exclusively
intended for research gathering become sites of exploration. These researchers have employed methods like living labs where participants, rather than designers, are able to reexamine their existing habits and trial new ones. These workshops and experiments “apply the social methods of disruption to everyday routines in order to render visible the objects and settings of everyday life” to the participants rather than the researchers (Marres, 2012, p. 79). In other words, through these experiments, participants trial alternative lifestyles.

While practice-oriented methods provide the mechanism for exploring and enacting shifts in routine, they assume a participant who already has a mindset toward an open framing of the space. These researchers reconsider the role of the participant, but they assume the participant is already in tune with the intentions of the workshop. But this is not necessarily the case. Participants may not yet be open to different ways of living. In other words, before trialing a particular shift, how do people adopt the worldview that the future is open to shifting?

In Scott et al.’s (2011) model for practice-oriented design, futures are first opened up and then closed, as the participant selects and trials an alternative practice. They refer to this as a “continuous alternation between discursive and practical modes” (Scott et al., 2011, p. 7). In this research, I am most interested in the opening up and discursive mode. The living lab provides a model for the practical mode but there are fewer precedents for the discursive mode — perhaps because as designers we are most interested in diving into the doing. Nevertheless, without first opening up possibilities through the discursive mode, the exploration will not stray from the present reality.

In “Ethnographies of the Possible,” (Halse, 2013) Halse argues that anthropologists should reorient themselves from concerns of the now toward activating futures. In arguing for this shift, he describes the design methodology — participatory prototyping workshops — he has used. He argues that, while these methods sound tenuous in the abstract, they become potent when used in concrete scenarios where futures are contested and disputed both internally and between stakeholders. They can provide a means of negotiating these conflicting possible futures. Designers can take ownership of these methods.

Why Downsizing

In order to understand the problem space, I conducted exploratory research that involved interviews and a cultural probe — a set of seven pamphlets to be completed over seven days tracking how participants associated practices, things and the process of ridding (Figure 1). Eight people who were or had recently downsized their home were interviewed and three completed the probe. I conducted two phases of interviews with eight participants. Three of the participants were men and five were women. Seven were above the age of 50. Five were retired and three were still working. All participants were engaged in a voluntary downsizing.
One approach to encouraging a mindset of open possibility is to work with people who are in moments of transition. When people are downsizing their home or having their first child, not only is their entire network of things changing, but their routines and practices are as well. Though often recognized by marketers as rich moments for intervention (Hill, 2012), life transitions are often neglected by designers who see their participants as static. Designers working under the framework of social practice theory have begun to counter this, but typically use design methods to create moments of transition rather than working within existing transitions (Scott et al., 2011; Kuijer, 2014).

Life transitions are a rich time in which to work because typically static routines and practices shift. Change in enough practices opens the entire fabric of networked practices to shift (Shove, 2012). During the process of inventorying and sorting, downsizers are very directly considering their things as well as their practices. This creates a window of opportunity to enable downsizers to reflect on how they are shifting their practices. Once they have completed their downsize, the window of opportunity will have closed and downsizers will re-establish a new network of things and practice patterns. These practices will no longer be so susceptible to change.

In these moments of transition, people are already wrestling with visions for their future. To think that the idea of ‘futuring’ would be something that is entirely brought by the design facilitator is, of course, naive. The downsizers I worked with were in a state in-between significant changes in their lives. Many had recently left the workforce (or were considering doing so) and had children who had recently moved away. Though they were all in good health, they were beginning to plan for future health deterioration. Through the downsizing process they hoped to match their surroundings to their changing selves. One downsizer I worked with relayed that the best advice he received during the process was to “envision the life he wanted to live.” Downsizers are going about understanding their futures in different ways.

More evidence of futuring can be found in the different ways downsizers plan for change. While some downsizers making this change during the retirement years see this as a ‘final’ (or what one of Shove’s own participants described as a “future proof”) change, others consider platformed aspects of the change (Shove, 2012, p. 30). For one interviewee, the first downsize is an opportunity to purge her and her husband’s life of possessions and move to a more central location in the city. Then they would search for a ‘home base’ from which they could travel throughout the majority of the year. Downsizing is a moment in time when people are actively reflecting on how to construct their lives to fit both their present and future selves.

Downsizers do this work of futuring in relation to things. While discussing ridding themselves of things and moving, Gregson (2012) writes that “…destruction relates to the perceived impossibility (rather than possibility) of gifting… It requires the divestor to project these things into another social context (either known or imagined) and - project themselves into this context” (p. 102). As downsizers consider things that they will not bring with them, where that thing will end up is often determined by if they can envision it with another person. Things they can envision their friends and family using are given higher priority. These will be given away. Lower priority are items they can envision someone else (but not someone they know) using.
These will be sold. Items which they can envision someone using but not in any specific way will be donated. And finally, objects without envisionable practices will be trashed. In doing this sorting work, downsizers must imagine how things impact and fit into a person’s life. Or as Gregson indicates in the quote, sorting and ridding asks the downsizer to envision themselves living this alternative lifestyle. This act of envisioning, perhaps, can be nurtured and supported.

Additionally, the downsizers I spoke with were not exclusively concerned with their own future circumstances and practices. A nearly universal experience that my participants spoke of was previously supporting a family member through the downsizing process. Nearly every downsizer I talked to had a story about the painful experience of helping someone part with their things. Often, according to downsizers, there were far too many things and the older downsizers were too attached. Their move was not voluntary (as is that of all of my participants), but required, as they were often moving from their homes to a retirement community. After reflecting on this experience, many downsizers told me that they did not want to inflict this experience on their own children. They wanted to reduce their possessions now in order to spare their children that same experience of having to sort through things that were not their own and they had not accumulated themselves. Downsizers demonstrated that they were downsizing not just to create a more comfortable or convenient life but also to improve the life of the next generation. This seems to be an opportunity, or at least an indication, that while the downsizers did not talk about their downsizing in terms of increased environmental sustainability, they might be open to the concept if framed in this way.

Yet while downsizers are futuring, they do not have the tools to adequately envision and explore the changes that they are embarking on. Regarding the process, one participant said, “It’s kind of ‘chicken and the egg.’ I don’t know how much to get rid of before I know where we’re going to move.” Rather than shutting down areas of possibility with tools that help downsizers know what to get rid of, this is an example of a moment where design can open up the range of possibilities that people can envision. This mindset of open possibility is a first step toward a person reconceiving their environment and practices. As Halse (2013) points out, “they will rarely rest assured that ‘the world could be different,’ at least not with the addendum ‘in principle’” (p. 191). Instead, this work of creating mindsets of open possibility will allow people to explore different futures, whether independently or through designer-facilitated living labs or other workshops.

**Research Methods**

The initial workshops were conducted with four downsizers from the initial exploratory research. This included two women and a married couple. All workshops were conducted independently in the homes of the participants in the suburbs of Washington, DC and Milwaukee, Wisconsin. The workshops intended to work with existing contested changes that the participants were considering undergoing during their downsizing process. These ranged from the placement of a garage to storage space.

The workshop sessions lasted roughly an hour, consisting of three activities centered about these contested, potential changes. The first activity involved framing the problem. To frame the
problem, participants were asked to describe their current situation, and then describe a preferred situation and what the situation would look like to achieve this. Then participants used this proposed solution to create a *wicked solution map* (Figure 2). Wicked *problem* maps (sometimes described as system maps of wicked problems) recognize that problems are embedded in a network of related problems and attempt to map that network (Irwin & Kossoff, 2017). The wicked *solution* map instead intends to map the network of repercussions for any given solution.

![Wicked solution map example](image)

**Figure 2**: Example of a partially completed wicked solution map around the issue of ‘having to wash dishes by hand’

The exercise is intended to encourage participants to think more broadly about unintended consequences as well as trade-offs in design choices and practice shifts.

The participants were then asked to take the current situation and reassess how they might address their dissatisfaction with it if they were presented with different values and constraints. These were represented by a 2x2 matrix (Figure 3). Along one axis ran good health vs. bad health and along the other ‘value thrift’ vs. ‘value abundance.’ This encouraged participants to reframe their problem with the support of the limited framework (to provide both a starting point and avoid overwhelming the participant with possibility).
In the third activity, participants were given cards depicting ways in which people downsized (i.e. into a ‘tiny house’ or into an ‘intergenerational community’). To create familiarity with these downsizing outcomes, participants were asked to arrange the cards according to how similar they were to the participants’ vision for their downsize. Then participants were prompted with the idea that each of these ways of downsizing embodies a particular set of values. The participants were then asked to describe how someone with this particular set of values might resolve their dissatisfaction with the problem (Figure 4).
Discussion

These mapping exercises provide a means to reveal and explore unconsidered futures. These methods and tools are not intended to be applied as-is to each decision that needs to be made during the downsizing process. Instead, they are intended to provide a reframing of the process of problem-solving and decision-making. They are a framework to explore ‘how things could be otherwise.’ By moving back and forth between the frame of one’s own preferences, choices and values and alternative preferences, choices and values, participants are given new ways to consider and articulate futures.

For some, the activities led to concrete shifts in their understanding of the problem space. For one participant, the third activity led to an entire reframing of her problem. In the first activity she had proposed that the scenario that she was dissatisfied with was having to walk to her car in the cold winter. Her proposed resolution was to move into a home with an attached garage. During the card sorting activity she found that every solution she was proposing involved living without a car (even those she associated closely with her own desired downsizing outcome). While she recognized constraints keeping her from realizing this outcome, she had a new frame for the problem.

At the same time, the frameworks helped participants develop possibilities that they would not have thought of previously. For example, brainstorming ideas for the quadrant of the 2x2 matrix that she did not associate herself with, the participant discussing ideas for her walk to her garage developed presently actionable solutions. She thought someone might start wearing shoe grips to walk to the garage in the snow. She realized she could actually start doing this now before she had downsized and exclaimed, “I don’t know why I didn’t think of this before!”

For others, these methods may not manifest as a direct reframing of a particular problem but as new ways to communicate (with oneself and others) about existing unresolved concerns. It creates a space to discuss previously unspoken concerns between affected parties. For the couple who performed the activity together, completing each activity was much more challenging than with the individual participants. Both had different responses to the activities and even different interpretations of the prompt. Each also had drastically different thoughts on how they were currently and ought to be solving the problem they decided to frame in the first activity. One participant thought that they ought to be adding more space to their home to accommodate their possessions while the other believed the solution involved better organization and discarding of current possessions. Through the initial framing and mapping activity they discussed and decided both activities would need to be involved in the process of downsizing. However, they were able to negotiate and determine that adding additional space would take precedence.

For those who do not reframe their decision-making, the activities are most valuable as prompts for discussion around contested futures. For example, Kjærgaard and Otto (2012) as argue, when realizing that the children involved in their playground future study were not making innovative prototypes, “children and designers did not have to see the same things in these props. They were merely intended to serve as a common ground for negotiating design ideas from different perspectives” (Kjærgaard & Otto, 2012, p.182). Just as Kjærgaard and Otto (2012) understand that the participant and the designer do not have to see the same thing, neither do the participants themselves. In fact, the materials provide a space for negotiating these contested ideas, beliefs and understandings that might have otherwise gone unspoken. However, as became
evident, these activities are most useful when all parties involved in the contested space are present. While they are helpful for sorting out and expanding one’s own conception of the possible, they gain their power when facilitating the conversation between many.

**Conclusion**

This initial workshop serves to put a stake in the ground to demonstrate the potential of how design mapping methods can be applied in the service of creating an expanded range of future possibilities in participants. The maps are not intended as research material for the designer but instead are intended to support participants in their process of transition that is modeled by practice-oriented design. The workshops demonstrate the potential of working with participants who are already in periods of transition rather than forcing transition.

While the sample size was small, the workshops demonstrate that the mapping exercises can both expose participants to previously unconsidered potentials and serve as a point of negotiation between parties. It would be worthwhile to consider the role that these exercises could have for a group of participants who are navigating similar issues such as downsizing. Scott et al. (2011) argue that working in collaborative groups this way could provide three benefits:

1. Provide ‘legitimacy’ to challenges to normative practices
2. Create mutual ‘trust’ around stepping outside of social boundaries
3. Motivate participants as they implement or explore these potentials (p. 286)

Just as with the married couple, utilizing these methods with collaborative groups may reveal additional benefits.

Applied in this manner, design research methods, once applied by designers to frame the problem space for themselves, have new purpose and an end in and of themselves. Just as Halse (2013) argues for a new role for anthropological ethnography, so too can design research methods be tasked to explore contested spaces to “materializing ideas, concerns, and speculations… crafting accounts that link the imagination to its material form… and creating artifacts that allow participants to revitalize their pasts, reflect upon the present and extrapolate into possible futures” (p.194). A mindset of open possibility will prepare people to engage with previously unexploited futures, especially relevant in contested spaces like issues of sustainability, both independently or through designer-facilitated living labs or other workshops.

This paper has proposed concrete methods for creating mindsets of possibility in the scenario of downsizing. A full repertoire of methods and tools that can be used to open up futures can be developed from this initial pilot. Though an open mindset of possibility and an opening of discussion around contested issues could be the intended outcome of these methods (as in this case study), these methods could also be integrated into a more traditional human-centered design process with a product, service or strategy outcome. Once design research methods have been reconceptualized in this way, the challenge remains to explore their potential.

Lisa Otto

Lisa Otto is a recent graduate of the Master of Design (MDes) in Design for Interactions program at Carnegie Mellon University. She completed her master’s thesis on engaging non-designers with futuring methods during the home downsizing process. She currently works as an experience researcher at EchoUser in Washington, DC.
Raising Crime Awareness through ‘Design Thinking’ within a High Street Retailer in the United Kingdom

Meg Parivar, Ph.D. Research Design Candidate - Design against Crime - Lancaster Institute for Contemporary of Art (LICA) - Lancaster University, United Kingdom, maparivar@gmail.com

Dr David Hands, Supervisor, Course Leader of MA Design Management Lancaster Institute for Contemporary of Art (LICA), Lancaster University, United Kingdom, d.j.hands@lancaster.ac.uk

Abstract

Since the 1800’s, England became an industrialised country and experienced extensive urban growth, so sales associates chose this location to establish large stores. Towards the end of the nineteenth century, the aim was to create the stores to entice customers through space, impressive architecture, interior design and the elegant display of merchandise. At the same time, the display techniques were growing to promote sales. Therefore, more retail equipment manufactured and supplied for displaying products in the stores. This significant variation led the retail industry as that goods could be touched by the customers and they were not accessible only through retail assistant anymore (Whitaker, 2011). Since then due to this new differentiation, retailers have been experiencing a significant change in their customer’s behaviour. Now the retailers are trying to give a brilliant shopping experience to their customers with more reason to increase the sale (Ebster, Garaus 2011). However, there are some restrictions to this strategy that afford excellent opportunities for shoplifters and opportunist criminals. Store design can be a fantastic and efficient tool to increase sales. Also, it could significantly increase the chance of retail crime. This paper examines how to minimise criminal activity in retail environments to reduce loss prevention and retail shrinkage by raising awareness through design thinking. Therefore, interviews, observation and exploration were done based on the experience of employees and customers in ‘The High Street Retailer’. The research project outcome included a creative retail crime learning package and a digital platform to raise awareness and improve communication.

Keywords: Retail crime, Design against crime, Design thinking, Raising Awareness, Crime Prevention

The focus of this paper is on one of the largest and successful retailers in the United Kingdom. However, due to confidentiality purposes, the name of this retailer remains anonymous and is referred to as ‘The High Street Retailer’ throughout this paper. Retail crime is one of the most commonly committed crimes in the United Kingdom and because of the promotion of the sale by product accessibility strategy ‘The High Street Retailer’ is a comfort shopping zone where creates a fantastic target and environment for shoplifters’ activities; therefore the aim of this research focuses on how to reduce crime within design thinking through creative solutions. The research approach is the strategy to direct the study; hence the research methodology supports the work and methods and collects data; furthermore, it includes observation, diary and interview that allows for the compilation of
valuable data. Through the collection of this data, it suggests that the core problem is the lack of employee awareness of criminal activity within ‘The High Street Retailer’; as a result, it is important to inspect and establish staff training development (CPD) to introduce the type of retail crime and how to reduce its occurrence. Moreover, this paper illustrates the value of raising awareness through a ‘Retail Crime Learning Package’ and ‘Digital Platform’ in improving retail crime prevention.

**Literature review**

**Retailing in the UK**

The United Kingdom retail sector embraces all types of businesses that sell goods to the public that includes large retail chains, department stores, independent stores and virtual stores. Over 3 million people are employed in the retail sector, and the retail industry produces almost 5% of the United Kingdom’s GDP and more than 5% of the value generated by the economy each year and contributes around £17.5 billion in taxes to the country (UK Trade and Investment, 2014). The UK’s global brands are successful retail elements to attract inward investment and London is at the centre of this success as a leading shopping destination. The role of the retail sector is fundamental to the growth of the economy in the country, about 9% of all VAT-registered businesses are related to the retailers, and more than £300 billion sales were estimated which were from retail sector (UK Trade and Investment, 2014). By the 1800’s The United Kingdom became one of the industrialised countries where attracts businessmen to establish small or large retails. Also creating stunning stores and giving pleasant shopping experience became the main goal to entice people and promote the sale (Whitaker, 2011). Therefore retailers started experiencing a significant point of their customers’ behaviour. The retailers aim to create their store impressively to increase the sales. However, there are some poorly designed spaces within their sales floors that could provide excellent opportunities for shoplifters and other opportunist criminals (Ebster & Garaus, 2011). Retail crime is one of the most commonly committed crimes in the UK, according to the British Retail Consortium survey 2015, the approximate number of crimes experienced by the UK retail industry was 4,120,395 in 2015, and customer theft was 3,401,948. Shoplifting by organised criminal groups has since developed as a serious issue to leading retailers. The value of products, money or services stolen from stores costs an average of £241 per incident. 750,144 offences were resulting in loss or damage to possessions in 2014-15 but said the real figure is more like 4.1 million. Retailers are facing an increasingly sophisticated criminal, they need more help and support to respond to the threat (British Retail Consortium, 2015).

![Figure 1: Retail crime, by number of incidents, 2013-2014 and 2014-2015 (British Retail Consortium, 2015)](image-url)
According to Sosa (2015) ‘The High Street Retailer’ is one of the retailers that have been a significant target for retail criminals. Retailing strategy in the UK is to satisfy consumer needs, which is happening through promoting sales by attractive store design and layout (Bamfield, 2012). The eventual aim of ‘The High Street Retailer’ is customer satisfaction. This is their primary reason, along with low costs; this retailer provides a comfort zone to his customers (Azad, 2016) and this comfort creates a fantastic target and environment for shoplifters’ activities. This retailer in the city centre of a major city approaches police more than three times a week to report shoplifting crimes (Sosa, 2015).

The amount of money and stolen items in retail crime is higher than many other types of burglaries. Retailers are confronted with the massive number of retail crime cases (Bamfield, 2012). British retailers are losing over £1 billion worth of products every year. Most of the products are stolen by shoplifters. There are various facets of retail crime in the retail industry, including Shoplifting, Employee theft, Counterfeiting, Supplier fraud, card fraud, cybercrime and criminal damage (Press et al., 2001). This study focuses on shoplifting or customer theft activities particularly related to ‘The High Street Retailer’. This issue is considered as the highest problematic issue that is in front of every retailer. Types of shoplifters can be divided into six diverse groups, including Professional, Opportunist, Impoverished, Substance Abuser, Thrill Seeker or Juvenile and Kleptomaniac (Fischer, Halibozek, 2012). Retailers need to be more sensible for loss prevention and work on the issue together. However, they share ideas with other retailers to limit crime, and also they collaborate with the police, government, local government and local crime reduction agencies. Retailers are determined to convince Police and the Home Office to put a greater emphasis on retail crime (Bamfield, 2012). According to Wootton (2015), £100,050,000 was taken away from the police budget in 2013 which left them with little money and pressure. Their focus is on issues which damage lives, and retail crime is not their priority. Retailers need to take responsibility and think about their issues directly, and instead of policing and arresting shoplifters, they need to prevent or reduce crime (Ebster, Garaus 2011).

Design against Crime through Design Thinking

Preventing crime is not a problem only for the police to think about and deal with; it also can be addressed through design (Armitage, 2013). Designers need to be focused on people who they design for, as well as people who they are designing against to prevent crime and opportunities (Home office, 2010). Crime is considerably about opportunity; around 80% of the crimes are opportunistic (Wootton, 2015).

Crime brings a cost to individuals and retailers; it means anticipation of criminal costs, and the damage of criminal activities to the businesses and responding to crime (Home office, 2010). Designing against crime and criminals’ activities reduce the crime and damage of criminal actions through designing a service, education, environment or product that are appropriate for the situation. Design against crime is fairly new; the aim of this discipline is to prevent crime through design which commenced in the United Kingdom in 2000 (Gamman, Thorpe, 2006).

Through design against crime thinking, designers need to consider the prevention at the starting point of a project; therefore, they can prevent crime from happening, or reduce the opportunities for criminal behaviour (Home office, 2010). Design thinking is fundamentally a human-centred innovation process that underlines the whole practice which includes observation, collaboration, learning, visualisation of ideas, concept prototyping, and concurrent business analysis, which eventually encourages creativity and innovation in an organisation (Lockwood, 2009).
Design ‘thinking’ guides the way to how to confront the complexity in an innovative way (Moottee, 2013). Furthermore, businesses will always need to transform and innovate for continues (Cooper & Press, 1995). Changing a society means changing problems and issues; therefore, it is necessary to think and comprehend the issues differently; to think through something is to understand, to grasp and to figure it out (Lockwood, 2009). To multi-disciplinary design thinking, and another crime science methodologies including crime prevention; design thinking develops and applies a responsive design approach through the user-centred method of the design process. The process addresses miss-users, abusers as well as users, at the heart of a human-centred approach. The process inspects the new approach as well as re-designing existing strategies, connected to user-centred thinking (Gamman, Thorpe, 2006). Moreover, based on the research and former contexts and studies, the approach of this study is to find a solution within “design against crime thinking”.

Research Methods

Aims

The research focuses on ‘The High Street Retailer’ to identifying retail crime, including customer theft, damage, counterfeiting and fraud to reduce opportunistic crime through design thinking techniques.

Objectives

- To identify the process of retail crime and the nature of the crime in the store.
- To identify opportunities for retail crime and to explore what factors create opportunities for criminals to commit the crime.
- To identify what kinds of products are attracting criminals; this research illustrates what type of products are the main target for criminals.

Methods

As the aim of the research is to analyse specific issues within the boundaries of a particular environment or organisation, case studies method has been identified as the most appropriate method to explore the issues. Due to the large scale of the research investigation, the different departments and sections will be observed step by step, concerning layout and design to see how they function based on security aspects, staff activities and customer serving. Also, how staff adhere to security procedures and how the customer behaves during their shopping process. Three categories are collected for research, included shop floor, fitting rooms and till banks. The rationale underpinning this research area is based on empirical evidence; in the first stage, empirical method of the research investigation enable this study to achieve invaluable knowledge with observation and diary for the efficient recording of the environment, people, behaviours and relations. In the next stage, the research method uses a qualitative study approach to identify the core issues, through focus interviews in ‘The High Street Retailer’ to have direct interaction with contributors, to collect their opinions based on their experience and knowledge. Prototyping is conducted to participate in design through personal and group engagement (Hanington, Martin, 2012).
Limitation/Implication

The present study investigates different departments within ‘The High Street Retailer’ to identify retail crime in a different situation and environment, and it is a starting-point for further research and action in other branches within the stores.

Discussion

Three categories have been collected for research, included 1) shop floor, 2) fitting rooms 3) till banks. The observations were undertaken within different sections and at several times of trading hours within the store in weekdays and weekend.

The Framework for Implementation

Due to the large scale of retail crime in retailers including ‘The High Street Retailer’, the top crime prevention issues have been selected based on observations and interviews as over,

• **Fitting Room**
  • Counting and controlling hangers and items (Checking In/Out)
  • Controlling customer’s grooming
  • Making sure the returned items are new and not from other shops

• **Till Bank**
  • Keeping the shopping bags behind the counter until the end of the transaction
  • Comparing the prices of the system and checking the price tickets and descriptions
  • Checking the bags and luggage and pockets of items

• **Shop Floor**
  • Being aware of blind spots and the areas with mirrors
  • Being aware of organised criminal activities
  • Being aware of products, brands and offers

• **Goods and Recovery**
  • Keep the fixtures and shelves organised and tidy
  • Pick up the products from the floor

Raising Awareness

The policy of the company is that before new employees start working on the sales floor, they are required to attend an induction session which takes place for about 5 hours on their first working day, as such raising design against crime through design thinking could be incorporated within this induction process. At the moment this core issue does not have a place in the company’s induction outline and programme of activities. The question is how to hold this session to ensure the best outcomes.

Having team briefing sessions between staff, management and security is another way to ensure staff are vigilant in understanding how to prevent crime through a few simple activities, such as good customer service or keeping the store tidy and reporting unusual activities. However this is another core issue which does not exist seriously and regularly. By investigating data and information, it is clear that core problems are a lack of communication and employee awareness. Therefore, it is critical to review staff training development (CPD) to introduce the type of retail crimes and impacts and how to reduce
them. Design against crime awareness is an effective method to make employees conscious about retail crime and to learn how to work and collaborate besides each other to reduce crime and make a safe and pleasant workplace.

Learning Methods

Several interviews and surveys have been undertaken at ‘The High Street Retailer’ to find out how people would prefer to update their knowledge at work. The survey results explored that 45% of participants would prefer to listen to the experts to learn the new knowledge and 34% of people would prefer videos and role playing activities. As a result, listening and watching are two popular learning methods. Furthermore, by using visual thinking and learning methods, learners understand and retain information. Some stated that they need to see data to learn and recall it subsequently.

Recommendation and Initial Concepts to Raise Awareness

Based on this current research, two concepts are suggested for the result of the project, which are the development of a ‘Digital Platform’ and running an effective ‘learning package’. The process of retail crime is cumulative, and although unwanted costs are likely to be incurred through shoplifting activities over time; running a visual and dynamic learning package and digital platform as a main communication channel within the store will greatly improve crime reduction activities.

Concept 1 - Retail Crime Learning Package

The survey results identified that employees would prefer to listen to experts; however, the second favourite option is watching videos and role plays. Therefore one of the suggested concepts is to combine two methods of learning, including an auditory and visual technique to make it more motivating and engaging. The suggested learning session concept is based on the flash cards including question cards and visual answer cards in two different boxes. The concept has been tested through several workshops with over 20 members of staff, and the results showed that this method made the staff get engaged in a relaxing atmosphere. At the end of the session, it was clear that employees had a better understanding about retail crime and what they need to do to prevent crime.
According to the observation and interview research, 'The High Street Retailer' lacks a platform regarding communication and connection between staff and the senior management team. The only existing channel of communication is a platform for booking holidays and staff boards displayed throughout the corridors. The suggestion is to use this opportunity to establish a digital platform for the employees for two purposes; first embedding 'retail crime visual learning session' into it to allow staff to become more engaged and share their experiences with members of staff. Secondly, this platform can be used for other channels such as health and safety compliance and other company procedures. By logging in and using the website for different purposes, staff will be
indicated to watch the retail crime pictures and processes constantly, where are situated on the home page.

Figure 3: Retail crime digital platform, 'The High Street Retailer’ (Authors own)

Conclusions

This paper has raised a range of concerns regarding retail crime, specifically shoplifting issue and predominant costs of retail crime activities in British retailers. The study illustrates that retailers suffer from a large amount of shrinkage loss, and there are several reasons why it is not simple and economical to resolve the issues in a short period; the study argues that one of the most effective solutions is to embed a new culture to the business through design thinking. By exploring key findings of core issue related to retail crime, this study emphasises that lack of collaboration and awareness in the retail store causes business shrinkage loss which can be resolved through the effective and innovative learning channels. This study introduced a creative and effective learning package and digital platform to raise design against crime awareness through design thinking. Furthermore, adding the visual and dynamic learning package to the training sessions and running the digital platform as a main communication channel within the store, will greatly improve crime reduction in the future. This can happen through design thinking, as the designed learning package encourages staff to challenge and think about what the issues are, what is the best approach to confront it based on policies, how they can deal with the challenging situations and what is the best tactic to meet the store crime prevention requirement and how implement the new strategy to make it happen. However, the training sessions have commenced recently, and over 50 employees have already received training, and positive impression and commitment showed by them; only five employees had a good knowledge of retail crime and security procedures. The result of the training will be measured between two stock takings which are every six months to explore the effectiveness of training content.

Author Biography
Author Name: Meg Parivar

I attained a first-class honour degree in product design from the University of Salford and achieved a master’s degree with distinction in design management from Lancaster University. Currently, I am the first-year PhD design research candidate at Lancaster University, and my research interest is ‘design against crime to reduce shrinkage in the retail sector through design thinking’. As I am working in one of the largest High-Street retailers in the United Kingdom, I always intend to blend my design thinking skills and experience within the workplace by bringing my projects and research into the business to solve the problems, as the design is about issues and solutions.

I have been allocating my experience in two broad areas as over,

- Design against crime - Retail Crime
One of the research project was "Raising awareness through design thinking to reduce criminal activity within the retailers in the UK." The outcomes include two developed and validated concepts which are a learning package and a digital platform.

- Health and Safety in Retail
I have designed a trolley for replenishment, integrating four functions to reduce the accidents in the workplace and promoting the sale. Using the concept as a trolley as well as rail, folding table and a cage reduces the amount of equipment on the shop floor and accidents.
PRODUCT DESIGN BRIEFS AS KNOWLEDGE-BASED ARTIFACTS OF CROSS-FUNCTIONAL COLLABORATION IN NEW PRODUCT DEVELOPMENT

Ian Parkman, University of Portland, Portland Oregon, USA, parkman@up.edu

Abstract

Contemporary research in business strategy, new product development, and design management has suggested that cross-functional collaboration within team-based environments is critical to successful product development processes. However, scholars have also demonstrated that the mere presence of inter-functional structures does not necessarily lead to better outcomes. Indeed, the very differences which cause cross-disciplinary teams to result in improved design processes may also lead to friction as team members’ backgrounds, orientations, and training often cause them to have different perspectives on what information is important to the product design process and to solve development-related problems. Improved understanding how to integrate information from differing functional areas is a clear emphasis of research, yet very few empirical studies have precisely defined the units of knowledge flowing through NPD projects, differences in importance of information elements by functional area, or the structures which may facilitate the sharing of information within NPD. This study presents an investigation of product design briefs as knowledge-based artifacts of cross-functional collaboration within NPD. Drawing on a proprietary sample of 68 briefs analyzed through an expert rating procedure alongside survey questionnaire of 153 product development managers our results define 51 information elements commonly shared between functional areas during an NPD project. We organize these information elements as eight factors, categorize the “importance” of each element to NPD success, and describe differences in evaluation from across three primary functional domains of NPD: (a) Design, (b) Marketing, and (c) Engineering/ R&D/ Development.

Keywords: Product Design Briefs, Knowledge Management, New Product Development, Knowledge-based Artifacts

Introduction

Contemporary research in business strategy, design management, and New Product Development (NPD) has placed an increasing emphasis on the role of cross-functional coordination within team-based development projects (Brown and Eisenhardt, 1995; Kim and Kang, 2008; Borja de Mozota, 2006; Verganti, 2003). Cross-functional teams, described as groups of individuals drawn from various areas within and outside of an organization including engineering, marketing, product design, user experience, human resources, Information Technology, production manufacturing, distribution and operations working together to bring a new product project to market (Jassawalla and Sashittal, 2000). The academic literature has established that collaboration, coordination, and cross-functional integration are critical factors
for new product success (e.g., Madhavan and Grover, 1998). Indeed, the crucial role of cross-functional coordination has been emphasized by several Product Development Management Association (PDMA) best-practices surveys (see Barczak, Griffin, and Kahn, 2009). However, various findings have also demonstrated that the mere presence of cross-functional structures does not necessarily lead to better performing NPD processes (Kim and Kang, 2008; Olson, Walker, Ruekert and Bonner, 2001). Specifically, Cronin and Weingart (2007) contend that far from a panacea organizations frequently find that cross-functional teams result in conflict because team members’ backgrounds, orientations and training often lead them to have vastly different perspectives on how to best approach and solve development-related problems (Luo, Slotegraaf, and Pan, 2006). In a survey of 43 large Fortune 500 companies in the US Wall and Lepsinger (1994) found that the key issue impeding the effectiveness of cross-functional cooperative teamwork within NPD, affecting 80% of respondents, was the tension that exists between team goals and functional priorities, surfacing in the form of: Conflicting organizational goals; competition over resources; overlapping responsibilities; conflicting personal goals; a lack of clear direction or priorities; and a lack of cooperation.

This suggests that the ability to effectively create, share, and employ cross-functional information and knowledge within NPD is closely related to the presence of effective organizational structures to assist flows of information, facilitate teamwork, direct resources, and create alignment across functional areas (Alavi, Kayworth and Leidner, 2005; Luo, Slotegraaf, and Pan, 2006). Accordingly, the goal of this study is to provide an empirical analysis of a potentially powerful knowledge-based artifact that may act as a critical tool for cross-functional product development projects: the product design brief. Product design briefs are documents employed during NPD that specify the many requirements of an NPD project (Bruce and Daly, 2007), such as objectives, descriptions of the target customers and competitors, product pricing, along with a wide variety of product attribute details—e.g. shapes and colors, branding, materials, as well as holistic design attributes such as personality and meaning (Borja de Mozota, 2006). Although product design briefs have been widely referred to anecdotally in business strategy scholarship (e.g., Phillips, 2004; Bart and Pujari, 2007; Crawford and Di Benedetto, 2006) and design literatures (Jones, 1992; Bobrow and Dryzek, 1987; Acklin, 2011; Mactiver and O’Driscoll, 2010) very little research has empirically described their contents or explored the role of these potentially important documents as elements of cross-functional coordination during NPD.

**Literature Review**

Within the business strategy literature considerable recent interest has been focused on describing forms of cross-functional product development; driven by the realization that diverse NPD teams lead to more successful product offerings (Kim and Kang, 2008). As such, the role of knowledge in cross-functional coordination has been described as the vehicle that allows the overall capabilities of the firm to become integrated and directed toward successful new offerings (Moenaert and Souder, 1990). Underlying this conceptualization of “stocks and flows of knowledge” (Aaker, 1995). However, the precise forms, structures, and mechanisms by which cross-functional knowledge is collected, integrated, and directed during NPD have been underdeveloped in extant research (De Luca and Atuahene-Gima, 2007). To address this gap we examine product design briefs as knowledge-based artifacts of the highly tacit flows
of cross-functional knowledge within NPD.

Knowledge-based Artifacts and Product Design Briefs within NPD

Researchers in business strategy have emphasized the importance of codified, durable, and sharable knowledge-based ‘artifacts’ as tangible repositories of organizational knowledge (Melewar and Saunders, 2000; Melewar, Basset and Simoes, 2006; Luo, Slotegraaf, and Pan, 2006) that capture and store organizational culture, knowledge and learning as stories, arrangements, rituals, language as well as diagrams, schematics, sketches, and prototypes (Ulrich and Pearson, 1998). These artifacts facilitate the process of capturing, storing and sharing a firm’s knowledge and function as a clearinghouse to catalog and integrate the variety of technical and market information necessary for successful NPD (Alavi, Kayworth and Leidner (2005). We propose that product design briefs fit this characterization.

The British Standards Association defines product design briefs as, “A document that outlines the strategic direction for creative development, covering the specific task at hand, the communication objectives and strategy, and any elements that the executions must contain.” Phillips (2004) goes on to specifically describe the importance of product design brief within NPD as a written document outlining the business objectives and corresponding design strategies and target market for a product development project that codifies the various written communication, blueprints, diagrams and schematics employed during the new product development process (Bart and Pujari, 2007; Blyth and Worthington, 2001; Ryd, 2004). However, despite their importance to NPD, the creation and use of product design briefs has largely been described as ad hoc and unsystematic within firms (Redström; 2006). Accordingly, the focus of this study is on firstly, to empirically clarify the types of information commonly contained in product design briefs, and secondly, to empirically describe their use as knowledge-based artifacts of cross-functional coordination during NPD across three common functional areas; (a) Design, (b) Marketing, and (c) Engineering/ R&D/ Development.

Research Methods

Collection of Design Brief Documents

Because product design briefs typically contain a wide variety of strategically significant NPD-related information and knowledge, they have been considered highly proprietary by firms, which historically hindered their use in academic research. Product producing firms have been understandably reluctant to provide product design briefs for scholarly examination due to legitimate concerns around protecting intellectual property rights and competitive advantage.

This may explain, at least in part, the notable absence of product design briefs in extant NPD literature. To our knowledge, this sample represents the most comprehensive and systematic attempt to analyze the form and contents of these important documents. Our collection of product design briefs was accomplished through the generous participation of several key industry associations and organizations and by assuring firms that their product design briefs
would only be used to generate an initial listing of information elements for further analysis resulting in a final pool of 68 design briefs from 22 firms across 17 NAICS industry codes (see Appendix B).

**Expert Rating of Design Brief Contents**

In the first stage of analysis, a series of interviews was conducted to provide an initial list of product design brief information elements. Interviewees were all present or former high-level managers of consumer product firms and had deep wells of experience personally creating and managing thousands of product design briefs. These interviews consisted of listing exercises where managers orally described their firm’s processes for creating and using product design briefs during new product development as well as the variety of information and knowledge commonly contained in their firm’s briefs, conceptualized as “information elements”--e.g., words, text, phrases, concepts, ideas, figures (Paas, Renkl, and Sweller, 2003). In addition to this interview process, the initial list of information elements was informed by related literature in product attributes, product design, user interface design, R&D process management, technology management and new product development (e.g., Kim and Kang, 2008; Ehrich and Irwin, 2005; Bart and Pujari, 2007). These interviews and review of literature resulted in an initial listing of 138 information elements (see Appendix A).

In a second step, our initial listing of information elements was refined through an expert rating process. The focus in this stage was to confirm the listing of 138 information elements and distill the listing into a more parsimonious and manageable length by checking against actual product design briefs. Expert raters identified through our interview process were randomly assigned subsample of documents, alongside the initial list of the 138 initial information elements. Raters were asked to read through product design briefs provided and note information elements as they occurred in the document. For example, a product design brief for a running shoe that contains a bullet point providing information that the product is intended for, 

“[An] avid runner, who is highly involved with running, training for a sub-4 [hour]
marathon, at 40+ miles per/ week.”

could be taken as evidence of information elements: “Product performance”, “Status”, “Involvement”, “Prestige”, “Segmentation”, “Intended use”, etc. rated on a scale from “3” -- Commonly Present to “0” -- Completely absent. As a result, elements such as “Workmanship” that were deemed to be regularly occurring information elements in product design briefs (mean = 1.21) were carried through while conversely, “Customization” was infrequently identified by raters (mean = 0.025) and was therefore dropped from further analysis. Through this process our listing of information elements was reduced from 138 to a more parsimonious 51 (see Appendix A).

**Survey Sample of Managers**

In order to further test the validity listing of our 51 design brief elements and to assess potential differences between functional areas a survey questionnaire was created and
submitted to a sample of managers within product research, engineering, design, sourcing, brand management and development for their firms (descriptive statics reveal the average years of experience in our sample is 12.7) by employing a non-probability snowball sampling technique (Churchill, 1995). The snowball technique is a judgment approach for sampling that is useful for accessing highly specific populations of respondents. In the survey respondents were presented with a randomized listing of blocks of our 138 information elements and asked to rate the item’s “presence” in their firm’s “Most recent product design brief” on a likert-type scale ranging from “1”--Never present to “7”--Always present. This process resulted in 174 usable individual responses from fifty-seven organizations, which is comparable to other studies of this nature that target highly specific populations (Churchill, 1995). In addition, frequency analysis reveals that respondents varied acceptingly across our three targeted functional areas: Development/ R&D/ Engineering (N = 45, 28%), Design (N = 47, 30%), and Marketing (N = 64, 40%) (see Table 1).

Following accepted practice, we employed Exploratory Factor Analysis (EFA) as a standard data-reduction technique to describe groupings of information elements contained within our product design brief documents (e.g., Flynn, Sakakibara, Schroeder, Bates, and Flynn, 1990). Factors with eigenvalues larger than 1.00 were carried for further analysis as defined by the Kaiser rule (Kim and Mueller, 1978). In addition, information elements that showed loadings of less than 0.35 were to be dropped from further analysis (Sethi and King, 1991), however, it should be noted that no information elements fell below this cutoff, which can be taken as evidence that our expert rating process produced a valid universe of information elements. Secondly, in order to ensure the reliability of the factors, Cronbach's coefficient alpha was also used to test the internal consistency, although all alphas were significantly above accepted cut-offs (Nunnally, 1987).

Our EFA process resulted in eight factors emerging from the 61 information elements (Table 2). These factors account for 77.4% of the variance (K-M-O statistic, 0.888; Bartlett statistic, 7267.65; significance = 0.000). These factors and their contents are discussed below.

Discussion

Product Design Brief Information Element Factors

To help rationalize our discussion of the eight factors that emerged from our EFA we employ the widely accepted categories of cross-functional knowledge identified by Hong, Doll, Nahm, and Li (2004) as organized below:

**Knowledge of Customers** (Hong, Doll, Nahm, and Li, 2004) refers to the extent that a firm encourages cross-functional collaboration in order to create a firm-wide, shared understanding of current customers’ wants, needs, and demands. Much business strategy and NPD literature, understandably, considers knowledge of customers to be an essential driver of product performance (Atuahene-Gima 2005). More interestingly, research suggests that organizations with heterogeneous understanding of market knowledge—i.e., information related to customers, competitors, and the industry environment in excess of that of their competitors (Moorman and Miner, 1997)—are more likely to design distinctive products that match the needs of its customer segments and stand out from rivals’ offerings.

Information elements contained in Factors 1, 3 and 7 appear to capture knowledge important to describing target consumers of a product development project (see Table 2). More specifically, Factor 1 relates to a variety of relatively tangible and explicit information elements, including the “Price point” for the product, “Sales price”, “Versions” of the product, “Target dates”, “Goals” and “Forecasts”. Factor 3 describes aspects of the product offering’s form, such as “Ergonomics”, “Product performance”, “Weight”, “Product quality”, “Workmanship”, and “Technical specifications”. Similarly to Factor 1, this information would appear to be generally explicit (e.g., information specifying the intended weight of a product). While Factor 7 contains information elements that characterize the “Risk”, “Safety”, “Health”, and “Sustainability” properties of the product as well as the corresponding development process. In total, these three factors appear anecdotally to consist of information provided by Marketing and Engineer/ R&D/ Development functions intending to communicate the various elements of consumer information that will help Designers create a more successful product—i.e., related to the focal product’s form, technical specifications, price point and quality.

In a second step of the analysis, to examine whether and how the perceived “importance” level of these information elements differed across functional area, a series of univariate ANOVAs was conducted. Results indicate that within the Knowledge of Customers category several information elements differed significantly across functional area: “Differentiation” (F (2, 153) = 3.70, p > .05), “Product performance” (F (2, 153) = 3.24, p > .05), “Technical specifications” (F(2, 153) = 3.23, p > .05), and “Sizes” (F (2, 153) = 3.98, p > .05). While “Price point”, “Consumer segments”, “Product-level positioning”, “Technology”, “Multiple versions”, “Sales
price”, “Earlier products and brands”, “New market introduction”, “Target dates”, “Project goals”, “Forecasts”, “Ergonomics”, “Weight”, “Product quality”, “Workmanship”, “Product risk”, “Product safety”, “User health”, “Sustainability of product”, and “Sustainability of process” did not differ at the p > .05 level. These results suggest that while the majority of Knowledge of Customer information is successfully communicated between functional areas (only 4 out of 24 showing significant statistical differences). However, among the information elements where significant differences were present (e.g., “Differentiation”, “Product performance”, “Technical specifications”, and “Sizes”) several interesting points emerge.

Firstly, it is curious that our “Size” information element appears to represent a significant difference across functional areas. This information would appear to be relatively simple to codify and communicate. However, again, this result may be taken as potentially powerful evidence that differences in expectations and assumptions may contribute to miscommunication of relatively straightforward information within NPD projects. Secondly, our results suggest, somewhat counter-intuitively, that Designers believe that both “Product performance” (mean = 4.09) and “Differentiation” (mean = 4.04) information elements are more important to a successful NPD project than Marketers (mean = 3.98, mean = 3.92 respectively). Based on follow-up interviews with respondents we interpret this result as evidence of incomplete cross-functional communication during NPD; in that Designers feel that they generally do not receive adequate “Differentiation” or “Product performance” information from Marketers, information that Marketers may understand much more implicitly. This disconnect becomes problematic when Designers are asked to translate this highly tacit cross-functional information into the final look and feel of a product-- for example, information elements related to “Ease of use”, “Appearance”, “Aesthetics”, “Usability”, and “Ergonomic form” may be intimately related to the correct interpretation of “Differentiation” or “Product performance”. This suggests that not only do Designers need Marketers to provide them with more explicit information related to the intended product’s specifications, the competition, the target market, the price, and so on, they also need deeper insight into the characteristics of the target consumer and to be regularly updated on changes in consumer needs, wants, desires, and “meaning” (Borja de Mozota, 2006; Verganti, 2003). This finding clarifies what Krippendorff (1989, p. 9) describes the role of Design as, “…making sense (of things)”. And that, “…the products of design are to be understandable or meaningful to someone”. (p.9) Verganti (2003, p. 36) goes on to define design-driven innovation as, “…an innovation in which the novelty of a message and of a design language prevails over the novelty of functionality and technology”. Our results provide interesting insight into the inherent complexity of sharing the “right” customer and competitor information between Marketing and Design functions during NPD—i.e., perhaps less “Price point”, “Technology”, or “Product safety” information and more insight into the holistic meaning the new product will deliver as consumers are starting to give more attention to the intangible value, meaning, and satisfactions of products (Dell’Era and Verganti, 2009).

**Knowledge of Internal Capabilities** (Hong, Doll, Nahm, and Li, 2004) refers to the extent of a shared understanding among the firm’s design and engineering, process, marketing, manufacturing, and other functional capabilities among product development members. This category is clearly significant to cross-functional NPD success because a shared understanding of the strengths and weaknesses of an employee’s functional area, along with adequate
understanding of the strengths (and weaknesses) of other functional areas, can help create product development processes that maximize the capabilities of the firm as a whole (Atuahene-Gima, 2005). For example, cross-functional teams have been shown to contribute to designing products that simplify manufacturing processes by reducing the number of parts per product and standardizing as many of those parts as possible (Chase, Aquilano and Jacobs, 2004).

Within our sample of product design briefs, Knowledge Internal Capabilities was captured in Factor 8 which contains information elements describing “Materials”, “Production facilities”, and “Production capabilities”. As there were no significant differences at the p > .05 level, our results suggests that broad agreement exists across functional areas as to the “importance” of these elements. Indeed, the rating for “Materials” was among the highest means and agreement in our data (Design = 4.04, Marketing = 4.27, Engineering/ R&D/ Development = 3.78). However, Öberg and Verganti, (2014) caution against celebrating such extreme agreement among Knowledge of Internal Capabilities as ideally firms should guard against myopia by constantly seeking out new information and knowledge that is not part of the company’s industry and context, since it will not be hindered by preconceived ideas.

Knowledge of Suppliers (Hong, Doll, Nahm, and Li, 2004) describes the shared understanding across a firm’s functional areas of their suppliers’ design, process, and manufacturing capabilities. Knowledge of Supplier information elements center on communicating practical issues of “Cost”, “Flexibility”, “Quality”, “Dependability” (e.g., on-time-delivery) and “Speed to market” for a firm’s product development projects. These elements of information have been demonstrated to be strong predictors of an efficient product development process, which leads to better firm performance (Koufteros, Vonderembse, and Jayaram, 2005).

Within our sample, Factor 5 contains information elements that describe two distinct groups of supplier information. First, there are elements describing “Tagline” and related “Promotions” information, alongside a second distinct grouping of “Product lifecycle” and “Distribution/ supplier” information. The separation among these groups highlight different constituencies within a firm in relation to what defines a ‘supplier’ relationship. More specifically, elements corresponding to “Tagline” and “Related promotions” information appear to be more relevant to downstream (i.e., closer the end user) marketing, promotions, digital media, advertising, sales or public relations consultants, or what Verganti (2008, p. 444-445) describes as ‘key interpreters’ of a product design. These actors include other product designers, architects, magazines and other media, suppliers of raw materials, universities and design schools, showroom and exhibition designers, and artists who may be sources of inspiration for Designers, rather than traditional up-stream supply chain production, manufacturing, or distribution partners. Examination of means differences reinforces these distinctions; for example, Marketeters and Designers consider “Tagline” (mean = 4.50, mean = 4.23) to be more important than Engineers/ R&D/ Developers (mean = 4.20) because they are likely using that information to communicate with up-stream actors. While, alternatively, Engineers/ R&D/ Developers rate “Product lifecycle” (mean = 3.89) and “Distributors and suppliers” (mean = 3.91) higher than Designers (mean = 3.83, mean = 3.64) based on their emphasis on downstream suppliers and codify that information within the product design
Knowledge of Firm Strategy (Hong, Doll, Nahm, and Li, 2004) captures the amount of shared understanding across cross-functional teams as to the firm’s overall competitive advantages and product development strategies. The successful management of multiple concurrent and overlapped product development projects is a distinct emphasis of contemporary NPD and design management (De Luca and Atuahene-Gima, 2007), which requires that each functional area maintains an understanding of their roles within individual development projects, as well as the wider firm strategic priorities.

Within our results Factor 2, Factor 4 and Factor 6 contain a wide variety of explicit and intangible information elements that contribute to a firm’s or NPD project’s competitive strategy. Defining the mix between and among these different information elements and Factors is one of the prime contributions of the study. Specifically, Factor 6 defines a variety of fundamentally explicit Marketing and branding elements like, “Graphics”, “Design Language”, and “Aesthetics”. While Factor 2 describes a number of highly tacit and largely emotional and symbolic information elements, including “Prestige”, “Status”, Styling”, “Authenticity”, and “Emotional appeal”. Factor 4 captures the more dynamic/active properties of a product such as “Consumer involvement”, “Product-User interactivity”, and “Expertise”. This findings appear to provide empirical support for Verganti’s (2003) concept of design-driven innovation as a strategy for creating complex “product meanings”, which refers to the holistic ‘purpose’ a product has to a consumer, made up of not only utilitarian, but also emotional and symbolic values. It is primarily focused on why people use a product, rather than what the product is or how it is used (Verganti and Öberg, 2013). For example, while research has shown that firms are able to communicate specific “meanings” (e.g. status, excitement, or luxury) through a product’s form the processes or structures employed during the product development process that contributes to the creation of ‘meaning’ in a product has not been clearly defined (Bloch, 1995; Verganti, 2008; De Luca and Atuahene-Gima, 2007).

Knowledge of Firm Strategy factors come together to imbue in firm offering’s what Creusen and Schoormans (2005) describe as the process of product appraisal, where consumers evaluate the physical properties of an offering (e.g., color, shape, and texture) in a holistic way in order to determine higher order categorizations of the product’s positioning and meaning within its market. For example, the ease of use, product-user interactivity, and novelty of Apple’s original Mac computer was expressed through color, form, and aesthetics (Ravasi and Lojacono, 2005). These subtle symbolic and experiential product cues allow consumers to express their actual, or idealized, self-image through an offering (Verganti, 2008).

Results of an ANOVA on Factor 2, Factor 4 and Factor 6 indicate that significant differences exist across functional areas in regard to the importance of information related to “Status” (F (2, 153) = 5.98, p > .01), “Authenticity” (F (2, 153) = 4.60, p > .05), “Consumer meaning” (F (2, 153) = 5.88, p > .01), “Touch” (F (2, 153) = 3.49, p > .05), “Sensory appeal” (F (2, 153) = 6.03, p > .01), “Emotional appeal” (F (2, 153) = 4.35, p > .05), “Product-user interactivity” (F (2, 153) = 6.95, p > .001), “Originality” (F (2, 153) = 10.05, p = .000), “Competitor comparisons” (F (2, 153) = 3.76, p > .05), “Innovativeness” (F (2, 153) = 6.58, p > .01), “Graphics” (F (2, 153) = 3.16, p > .05), and “Aesthetics” (F
Several of these elements are notable for their high F-ratios, particularly “Originality” and “Product-user interactivity”. In some regards, it is unsurprising that these highly tacit information elements illustrate points of significant difference across cross-functional teams, yet what may be surprising, and is a specific contribution of this study, are the mean differences which suggest that Engineer/R&D/Development functions consider elements traditionally understood to aspects of Design highest. For example, ratings of importance for “Touch” (mean = 3.56, relative to 3.36 for Designers and 3.34 for Marketers), “Sensory appeal” (mean = 4.62, relative to 4.36 for Designers and 4.50 for Marketers), and “Product-user interactivity” (mean = 4.11, relative to 3.47 for Designers and 3.63 for Marketers) provide tantalizing support for increased understanding-- or indeed enthusiasm-- for aspects of design management among Engineer/R&D/Development functional roles. Additionally, this finding can be taken as evidence for the increasing pace of innovation and ruthless competition that Gotzsch (2006) and Aaker (2010), among others, describes in mature product markets where it is difficult for companies to compete solely based on functionality and product features and functionalities are easily copied by competitors. In these contexts Knowledge of Firm Strategy with an emphasis on “meaningful” designs (e.g., through broad-based understanding and use of “Status”, “Authenticity”, Emotional appeal”, and “Aesthetics”) becomes perhaps the sole avenue to sustained competitive advantage.

Conclusions

This study provides a first-step toward understanding product design briefs from a knowledge-based product development and cross-functional collaboration perspective. This perspective addresses an important gap in extant literature around the question of how information and knowledge are employed during product innovation (e.g., Kim and Kang, 2008; Borja de Mozota, 2006; Verganti, 2003; Luo, Slotegraaf, and Pan, 2006). Although many researchers have acknowledged the need to develop more innovative approaches to assess the mechanisms that underlie product development (e.g., Griffin and Page, 1993), no previous empirical studies have examined product design briefs from the perspective of knowledge-based artifacts of cross-functional collaboration activities. Accordingly, our paper represents an important piece exploratory research and the results of this study identify several points for further investigation of the success factors for cross-functional cooperation in knowledge-based NPD. Specifically, beyond simply capturing and characterizing the knowledge typically contained in product design briefs these findings provide much needed clarity on the ways Design, Marketing, and Engineering/R&D/Development functions differ in their evaluations of these information elements. Additionally, our study provides empirical support for other work that has suggested that information shared within NPD has complex and holistic effects on product offerings such as Dell’Era, Marchesi, and Verganti (2010), who argue that new ‘technology’ and ‘materials’ knowledge communicated during cross-disciplinary NPD led to radically different product ‘meanings’ in the Nintendo Wii. The results of this study provide a potential roadmap for scholars and practitioners interested in facilitating flows of this tacit knowledge within NPD. Moreover, while the processes involved in NPD to encourage cross-functional collaborate are inherently complex, the results of this study present a first-step toward characterizing
knowledge-sharing, information use and organizational learning at more fundamental and manageable scale.

Secondly, this study provides support for the role of design management and product design within the front-end of NPD. Verganti (2006), among others, have argued that most firms do not adequately explore the possibility of utilizing design to exploit differences in tastes and demands in the consumer markets, nor do they develop a strategic vision for the use of design as a source of long-term competitive advantage. Some of the historic difficulty has been a lack of empirical findings that describe the distinctive competencies of design and the potential benefits of improved use of design management. The results of this study offer numerous avenues for future research (i.e., investigating flows of “Aesthetic” or “Authenticity” information elements through a product development project).

Finally, this study has implications for both researchers and practitioners. For researchers, this study provides an empirical foundation that may be important to future discussions of information-use, cross-functional coordination, knowledge-based assets, design management, knowledge management, and competitive advantage in NPD. As well as a foundation for other novel investigations of the potential role that product design briefs play as knowledge-based artifacts of a variety of firm product innovation processes and mechanisms. Practitioners, on the other hand, may use this study to refine their thinking about investments in cross-functional coordination structures within NPD and their firm’s overall use of information and knowledge as strategic resources. As Krippendorff (1989, p. 12) contends, “…meaning is a cognitively constructed relationship. It selectively connects features of an object and features of its (real environment or imagined) context into a coherent unity.” Thus, whether Design, Marketing, and Engineering/ R&D/ Development functions of the firm are aware of it or not, the products developed by a firm are always given a meaning by their consumers. The more successfully an organization can understand and facilitate flows of knowledge within NPD, the more likely the “right” meaning will be imbued in an offering.

Author Biography

Ian Parkman
Is an Assistant Professor of Marketing with the Franz Center For Leadership, Entrepreneurship, and Innovation at the University of Portland, USA. His teaching and research interests focus on knowledge-based product innovation, the creative industries, and product design. He has presented and published his work with the *Journal of Brand Management*, *Business and Society Review*, DMI: Academic Design Management Conference, American Marketing Association, Product Development Management Association (PDMA) Global Conference, among others. His Ph.D. is from the University of Oregon.
Feedforward in Interaction: A Case Study of Feedforward for a Glimpse of its Potential in Interaction Design

KAIST, Daejon, Korea, Richard Chulwoo Park, rcpark@kaist.ac.kr
KAIST, Daejon, Korea, Woohun Lee, woohun.lee@kaist.ac.kr

Abstract

The mental model is a well-known subject discussed by Norman. But problems of everyday things continue to exist. In fact, it is almost impossible to provide a coherent conceptual model for individual users, especially when an increasing number of technology-embedded artifacts have created new interactivities nowadays. In this paper, the classical user interface problem of a gas stove’s spatial mapping will be used to demonstrate how interactivity could be tamed by using the concept of feedforward. Feedforward is an important element to consider because it provides clear and instant affordance, leading to a mistake-free user experience.

This paper discusses feedforward based on the utilitarian perspective. The Previewable system will be introduced to compare the performance among conventional, touch-enabled, and hover-enabled gas stoves. Findings from a comparison analysis of its performance, its state of action, and the subjective experience will be shared. Furthermore, aspects of feedforward open up a venue in which to discuss its influence on the interpersonal and power relations that exist between artifacts and users with a design guide. The latent potential of feedforward leaves a lot to be discussed, but the findings in this paper strengthen the case for feedforward and lead to a glimpse of look at feedforward in context-aware.

feedforward; interaction design; micro-interaction; context-aware; experience;

Introduction

Have you ever been frustrated by a device when it doesn’t work as you wanted it to? A set of identical looking light switches, for instance, it is hard to know which switch controls which light, and we make mistake turning off restroom when there is a person inside. Likewise, we often experience frustration and irritation when the conceptual model is incoherent, contradictory, and ambiguous in relation to our mental model. This is a well-known design problem discussed by Norman (2002). Consequently, designers and researchers have been hard at work trying to make a solid and coherent conceptual model. However, the problem of everyday things is still present, especially when it comes to computer-enhanced artifacts, which, with the connectivity of modern technology integrated with sensors, offer a new form of interaction that’s sometimes immature.

This paper enquires into the problem of everyday interaction by giving a closer look at the classic gas-stove switch and its mapping issue. Furthermore, the paper looks into how should we look at modern technology and how we can deal with such complex interactions. We attempt to resolve
the problem at a micro level of interaction by applying the concept of *feedforward* and the *micro level of context awareness* in everyday things. Feedforward is like a preview when we mouse over on icons in computer, and which reveals what the contents is without actually turning it on. It is an important element to be considered in the user interface design because it provides clear and instant information, which helps users to see what will occur next or what it will do.

Controlling a switch may not be considered a difficult or serious situation in normal life. As a matter of fact, it is a trivial and probably tiny moment that people typically experience only momentarily. However, it is important to look at this matter as a design issue of user psychology in a context-aware context. We believe it will help to understand developments in interaction design in the near future.

**Background Research**

Ever since Norman introduced daily life issues, empirical research on the subject has been conducted in various fields (e.g., cognitive sciences, human factors, ergonomics, design, and user experience; (Arthuret et al., 1997; Downs & Stea, 1973). However, while designing appropriate affordance may sound ideal and simple, it is impractical in reality. A light switch and its mapping, for instance, resolves the issue with the affordance through spatial model, but it differs among people due to the fact that the cognitive map of a space is systematically distorted (Park et al., 2014; Tversky, 1992). Moreover, idiosyncratic differences among people, such as in culture (Oshlyansky et al., 2004), cannot be underestimated. And artifacts are becoming *smarter* and people are interacting with dynamic interactivity more frequently (Atzori et al., 2010; Cook et al., 2003). In other words, affordance is highly dependent on personal ability (Gibson, 1979). And universal design is indeed difficult.

As Djajadiningrat clarified (Djajadiningrat et al., 2004), feedforward is the information that communicates a possible action with an intrinsic functionality before a user performs an action. The aspect of feedforward is often employed in HCI such as *previews*. This has been typically used in the computing environment to prevent errors, improve task completion, reduce cognitive load (Sellen et al., 1992), and, in advance, gesture recognition (Cheng et al., 2013; Rekimoto, 2003). There are other examples of the use of feedforward in the form of a progressive gesture guide (Bau & Mackay, 2008; Freeman et al., 2009); furthermore, Ballendat (2010) propose proxemics interaction. The quality of understanding user’s action could be further connected to Weiser’s calm computing (1996). However, Weiser’s vision arguably lacks the clarity of interaction as Bellotti (2001) described. When interacting with things in which information is veiled, feedforward can unveil information to people and create a more user-friendly experience. For this reason, we believe feedforward has great potential to create balance between automation and empowerment of users (Park et al., 2014; Vermeulen & Luyten, 2013).

We designed the study for a ubiquitous computing environment. A macro-level understanding of user behavior within the behavior’s context is important; however, a micro-level understanding of behavior (Saffer, 2013) should also be studied in this context. We believe this micro-level understanding could be used to comprehend interaction design in a context-aware environment.
User Study

Figure 1: The states of the Previewable system: the illustration is based on Vermeulen’s design space of time and level of information details (Vermeulen et al. 2014).

A gas stove involves with a classical yet complex interface problem. We wanted to assess different range of detection of a user behavior that could influence on a latent interaction issue during the performance and experience. We defined this different behavior based on the proximity. We designed the prototype to manipulate three modes of conventional, touch-detectable, and hover-detectable gas stoves. Each mode can understand different levels of users’ action states. It recognizes whether a user is out of range, on the move (hovering), in the process of searching (touched or hovering), or in operation (clicked), as shown in Figure 1. A hover system provides continuous feedforward by gradual increments in brightness as the user’s hand approaches the knob. The touch-able system provides instant feedforward when a knob is touched. We have proceeded in the order of prototype experience, main tasks, questionnaires, and an interview.

Implementation

Figure 2. Implementation of the Previewable Gas Stove.

The prototype (see Figure 2) structure was built based on the commercial gas stoves. Potentiometers were used with the gas switch control knobs in order to reenact the haptic feedback of dialing and to detect when the knobs were turned on and off. To detect the distance from the knob to the user’s hand, we used short-range (4–30 cm) infrared sensors. The sensors were embedded above each control knobs. For efficient prototyping, we used a projector to manipulate the visual effect, which worked in the form of gas-hood light fixtures, drawing a target indication
for the tasks, and a visual effect of ignition. We recorded the user’s eye behavior using the eye tracker (45–75cm, 0.5°–1° accuracy in 0.1° RMS). The specification of the tracker was reliable enough for our purpose of use. The prototype uses Arduino-Processing PWM serial communication.

The task completion time, eye behavior, and all the activity performed by the participants were logged. The logging time started when the target indicators were on and ended when the user located the targeted burner by turning the knob on. The whole performance was recorded with a camera for the purpose of behavioral study.

**Experiment Setup**

In reality, a user wouldn’t operate a gas stove a number of times on the same spot repeatedly and simultaneously, which means the effect of perceived motor memory, learnability, and an increment of the physical load within the task should be considered in the analysis. To minimize the issues, the study sessions were scheduled with minimum three-hour intervals. The experiment was divided into two sets (see Table1), performance and experience within group study (A), and eye behavior for between group study (B). The order of the conventional and Previewable system were counterbalanced.

Twenty participants were recruited from the university (average age, 26.4; 13 males and 7 female). The participants were asked to turn on the targeted burner as accurately and quickly as possible. They executed 10 trials in each session. The target burner was randomized, and the mapping between the burner and the control knob was randomized with four types of mapping conditions.

</tbody>
</table>

An eye-tracking test was conducted with 10 additional participants (average age, 26.8; 8 males and 2 females) in order to understand the process of adjusting to the new system interface. The coordination and targeted burner in the study was randomized in every trial. Each session was carried out with a minimum 4-hour interval due to the learning effect. After each session, an interview and questionnaire survey were carried out with QUESI.

**Performance Enhancement Result**

All statistical results were based on a t-test. The performance was assessed with the task completion time and the number of missed clicks. Considering the fact that the user doesn’t use the knob repeatedly in real life, we used the results of the first three trials for the main performance analysis. We analyzed with QUESI (subjective mental demand, perceived achievement of goals,
perceived effort of learning, familiarity, and perceived error rate).

The Previewable system didn’t differ in terms of the task completion time, but it had a considerable effect on the number of mistakes made ($t_{(124)} = 5.462, p < .05$; $t_{(124)} = 5.145, p < .05$; Figure 3(b)).
The first and the last three trials reflected a performance comparison between the user in the cognitive stage and in the autonomous stage, as shown in Figure 4. The participants reduced the task completion time by 14.9% in the autonomous stage (conventional system; $t_{(124)}= 5.338, p < .05$); and they optimized their performance by 8% using the hover-able system (Figure 4, hover-able system; $t_{(124)} = 3.30, p < .05$). Participants outperformed when they were in the autonomous stage using the conventional knob.

The QUESI results indicate that the Previewable system enhanced the overall satisfaction of the subjective user experience. The results also show that the system enhanced its intuitiveness ($t_{(40)} = -8.13, p < .05; t_{(40)} = -6.47, p < .05$; Figure 5). However, there is not much difference between the touchable and hover-able system.

![Figure 6: Results for eye tracking. The figure illustrates the users' eye behaviors for the target Burner #2 (top row) and #4 (bottom row), and the differences between the conventional (a, d), the touch-able (b, e), and the hover-able system (c, f). We excluded the target Burner #1, and #3 results because the outcomes were similar.](image)

We want to comment on the subjective mental workload and other subscales (see Figure 5 (a)-A ~ (a)-D). The hover-able system’s subjective user satisfaction scores (12) on mental workload are higher than the touchable system’s (11.75). The difference between the two scores are not significant. However, if we take standard deviation (touchable system = 1.85; hover-able system = 2.12), it addresses some design issues regarding mental demand and the complex interaction technique. In short, participants felt a smaller cognitive load of experience using the hover-able system but found it more difficult to pursue their goals.

This result could be explained by the participants’ perceptual-skill-dependent behavior in the hover-able system which causes typical drawback of an absence of haptic feedback in the mid-air gesture interface. In the hover-able system, the participants don’t have to memorize mapping (therefore, there is less of a cognitive load), but they have to respond to a visual aid. Occasionally
they experienced being lost as a result of the discrepancy between motor and perceptual skills, which caused a delay at the end. Thus, the Previewable system may delay the task completion time, but it reduces the mental workload. Users seem to perceive mid-air gestures as an unfamiliar interface, which require a complex interaction technique, but the complex interaction could also sometimes be used to reduce the mental demand.

The Previewable system was distinctively more focused than the conventional system in the eye-tracking experiment. The participants’ eyes were distinctively scattered all over the gas-stove surface and control knobs (see Figure 6(a)). The participants were busy paying simultaneous attention to the target, the actual burner, and the control knobs. They also tended to be more attuned to the manner of using the hover-able system. They slid their hands over the control knobs and immediately understood which knob controlled which burner. They were able to make a decision without looking very much. Participants had to activate the knob by means of physical contact in the touchable system. Therefore, they occasionally needed to check the location of the knob, their hand, and the target.

On the assumption of all the participants’ equivalent short-term memory, the Previewable system is less demanding when it comes to memorizing, guessing, and evaluating, and perhaps, the hover-able system may not require these skills at all.

Observation and Interview Result

Compared to the participants’ prior experience with the gas stove, they all agreed that they could naturally engage with both the touchable and hover-able system. They reported that the Previewable system is intuitive to use. Most of the users emphasized how the system helped to resolve their uncertainty in the course of their actions.

The participants mentioned they felt less work demand, reduced sensory time, and more comfort and confidence in their actions. They particularly mentioned that it was unnecessary to think about mapping. These responses support the results of the QUESI and eye-tracking experiment.

We observed that some participants did actually spend some initial time figuring out the mapping by pointing with their finger. It occurred to participants that this process of understanding and configuring the system was mentally demanded as a task. Most of the users descriptively used the word annoyance when they were describing their experience with the conventional system.

Participants felt that there wasn’t much interaction difference between the conventional and touchable system. On the other hand, they reported that they perceived a hovering action as the pre-action state. We believe the participants’ perceptions of their action states relate to the interface physicality.

There was a clear individual preference for the hover-able system in terms of interface familiarity and subjective mental workload. The hovering technique seemed to be associated with common mid-air-gesture drawbacks in that it caused cognitive awkwardness when the user’s intended behavior differed from what was actually perceived. This finding supports the participants’ comments on the stability of haptic feedback.

Most of the participants mentioned the word mistake and described the difference between the
conventional and Previewable system. In addition, the subjective task completion time was much faster than in the conventional system, even though the actual task completion time contradicted this. Subjective mistakes were considered to be relevant to perceiving the action purpose rather than the action itself.

Participants who had experienced the Previewable system before experiencing the conventional system reported that they were confused and even embarrassed by the absence of feedforward. P12 mentioned, “I am not being treated fairly; I feel like I am not asserting my right when the information before me is taken for granted.” Most participants, like P12, appreciated the information. They particularly mentioned that they felt that they were being taken care of by the system and could rely on it more. However, it also addressed the dichotomous interaction design issue that exists between intuitive usability and loss of control. Few participants raised this issue of losing controllability. They were skeptical and even feared becoming incapacitated.

Discussion

User perception of time and mistakes

The task completion time could be very crucial for some devices in terms of usability. However, in the case study, which is trivial and infrequently used like in a real life, time can be perceived differently. Csikszentmihalyi (1990) explained the optimal experience as follows: “generally, after the experience we do not know where the time went; however, during the actual experience, time seems to stand still.” Most of the participants reported that the actual task completion time (hoverable < touchable < conventional system) hadn’t influenced their user experience; rather, the subjective quality of the time seemed to matter. Furthermore, the perception of time in the hoverable system is what caused this result in relation to subjective usability and satisfaction.

Considering the drawback aspects of the mid-air gesture (e.g., the absence of haptic feedback) and some negative comments made during the interview (e.g., losing controllability and unfamiliarity), it can be argued that the contradictory result related to the user satisfaction score reflected the possibility that a new or relatively difficult interaction technique could be tamed with appropriate use of feedforward in terms of the experience.

Generally speaking, mistakes are a decision or an action that we fear we will come to regret, and which arise from conscious deliberations (Norman, 2002). This is one reason why people become stressed or blame themselves when they fail in a simple choice they’ve made.
The participants were asked to describe a state of action and a purpose of action for each system in order to understand mistakes with regard to the state of action. The results show some aspects of an individual’s tolerance for making a mistake. We found that making a mistake in micro-interactions is relevant to perceptual action purpose and that participants’ knowledge of their actions is relevant for serving the purpose. For example, the user perceives a touching action behavior as an action in the touchable system, but the purpose of the action is to explore the system, as shown in Table 2. The same state of action, turning a knob, on the other hand, is perceived as executing the system. The participants perceive their action as a mistake when executing the knob if it fails to meet their goals. This is quite an important finding in interaction design because it implies that the same error made by different people could cause a different user experience.

It is almost impossible to create an absolutely error-free interaction design. However, we can make a perceivable system without mistakes. The interaction design strategy lies in the question of how to perceptually sublimate the purpose of executing the action. One suggestion is to have an implicit tutorial session for complicated functions by providing feedforward. This would lead users to build trust in a reliable system.

**Action states**

Figure 7 illustrates the action states’ difference among the (a) conventional, (b) touchable, and (c) hover-able system. The conventional system begins by following the execution, and the users evaluate their goals in relation to the outcome. The users repeat the steps until they achieve their goal. Therefore, the user experiences trials and errors, which are accrued as the number of possible actions increases. On the other hand, Feedforward shortened the process of action states by minimizing the physical steps in the trial-and-error process. Users start with the evaluation process. They would slide their hands over the knob and immediately see which one controls which burner. This would lead users toward a more error-free user experience (which differs from a mistake-free one).

![Figure 7. States of action cycle.](image)

We named the loop of the perceptual process before the action as the state of *hunch*. In the hunch state, the system could detect the users’ behavior before the user perceives an action. It then progressively attains the user’s confidence as it gradually carries out the user’s actions by feedforward. Eventually, it leads the user to make a confident decision. This aspect was also revealed in the interview where the participants reported that they gained confidence as they
approached the control. The downside of hunch, on the other hand, is that it causes a delay in the task completion time as the users keep evaluating the perceived information using their perceptual skills. A few participants pointed out that they often got stuck on the hunch state due to a discrepancy between their motor and perceptual skills.

**Manipulation techniques**

The participants tended to adapt to the system in which they actively used hovering and touch gestures as a means of searching. Buxton (1995) and Hinckley (2005) described it as foreground interaction, which refers to activities that are at the forefront of human consciousness. This interaction only lasts for a few trials in the process of learning during the cognitive stage. Once they became accustomed to the system, they tended to passively engage with feedforward. The interaction passes on to the periphery where feedforward information works as an assurance of the choice of their action (i.e., feedforward becomes feedback). This interaction occurs in the autonomous stage in which people usually control the artifact or system without thinking. This transition of states allows participants to undergo a process of adaption.

One potential benefit of feedforward is that it could induce users to adjust to a new environment or an unfamiliar interface and optimize their performance by adapting their behavior to the system. In other words, feedforward creates an opportunity for users to adjust their behavior in their own optimized way using the context of the system’s interactivity.

**Design Implication**

**Design guide for using feedforward**

First, designers must consider the context of interaction and usage frequency. Some artifacts may be used hourly or even more frequently, such as the use of smartphones. In this case, users can learn and adapt new features and remember how to use the system model without much effort. On the other hand, some artifacts may not be in use as often, such as a case study, in which users may consistently forget or be unwilling to remember. In this circumstance, using feedforward could be a powerful guide for the initial state of the artifact when the user is in the cognitive stage. Therefore, feedforward could be useful for guiding the novice by means of a more intuitive experience. However, we want to note that feedforward could also cause a delay in the autonomous stage, and some artifacts or expert users might perform best with a strong coinciding bond between the user’s mental model and the system model. Experts may not benefit when it comes to the task completion time, but they may benefit in the course of their action choice when they need to choose action carefully.

Second, a designer could transform feedforward as a different manipulation technique. Feedforward could even make different impressions in terms of user experience. We have demonstrated an intertwined interaction controllability between the foreground and background. In the hover-able system, the participants used feedforward as a foreground interaction to explore mapping of the system in the cognitive stage, and it was also used as a background interaction for users to confirm their choice of action in the autonomous stage. The system could also provide
confidence to users during the action process. This aspect of feedforward could be useful for designing artifacts that have to do with dangerous contexts involving highly uncertain controls that require insurance of the action.

Third, designers should be aware of the benefits and drawbacks of using feedforward. One of the benefits of feedforward is that it could provide confidence to users’ actions. Findings from the case study indicate that the participants used the information to make sure that their own action was appropriate, using the information as feedback regarding the results of their action. However, this particular interaction process caused delays in users’ performance because they tended to rely more on perceptual skills than cognitive skills. Perceptual skill dependency may significantly reduce the mental workload, but it also increases the task completion time. This is a crucial issue for design artifacts using feedforward.

Power Relation and Interactive Complexity

The case study reflects the important aspects of a power relation (i.e., the user is in control or is being controlled). Detecting a particular level of a user’s intended action is a prerequisite for feedforward to provide information before the actual action takes place. It helps users to trial-and-error-less control. However, some of the participants were afraid of losing controllability. They mentioned that the system helps them to achieve their goal without difficulty, but being in control makes them feel lethargic. They particularly mentioned that they fear losing skills as a result of system dependency. The skills they once had would become obsolete as a result of using this system. This issue of power relations addresses some questions. How much should the system take control and in what way can designers balance the comfort of being control free and the feeling of being in control?

The problem with digital artifacts lies in their short lifespan with the overloaded new features. People tend to maintain behavior they are accustomed from prior experience when they are confront with new digital devices. They seldom go through manuals and instructions even if this would save time in the long run by allowing them to take the initial time to optimize the system (Carroll & Rosson, 1987). This may be a problem related to the paradoxical nature of users. However, if we think about all the artifacts that require users to learn and study them, it’s clear that acquiring new artifacts is indeed a stressful experience.

Users are eventually going to adapt the interface and new features for their own good. Helping people in this way, however, lacks the ability to accommodate idiosyncratic differences among people. Using feedforward could be used as an explicit guide for the new interface. This instructive aspect of feedforward could lead users to achieve more intuitive usability in the feature, thereby overcoming their complicated lives.

Context-aware and Interpersonal Relation with Artifacts

If designers provide appropriate feedforward, it can build interpersonal relationship while interacting with the system. P18 stated during the experiment, “it (technology) didn’t make much difference (between conventional and the prototype), but I felt that I could manipulate it with entire dependency on the system with trust.”
In psychology, trust involves believing that the person who is trusted will do what is expected. According to Erikson (1950), trust is the first state of psychosocial development where it can lead to feelings of security and optimism. Building relationships with artifacts can be seen as a similar process as the above. Furthermore, numerous empirical studies have demonstrated how the experience of the product influences attachment and fidelity (Fenko et al., 2010; Schifferstein et al., 2008) interacting with it.

Although it cannot be conclusively stated, and many further studies may require, we believe that taking advantage of the concept of feedforward and context-awareness in micro-interactions could lead to the building of interpersonal relations with artifacts. Therefore, feedforward requires careful attention to the aspect of interpersonal relations in interaction design.

**Conclusion**

We have looked at the concept of feedforward as part of the process of usability. It provides explicit affordance to users, especially when a number of possible interactivities are uncertain. Nevertheless, products related to everyday things continue to miss these advantages. In particular, technology has become increasingly pervasive nowadays, and designers have to somehow mediate between technology and the physical world. Thus, feedforward should be addressed more in interactive design. The findings of this paper strengthen the case for feedforward and demonstrate why it is a prerequisite for user interfaces.

Feedforward can connect broken links in the cognitive process between intention and execution by disclosing latent action possibilities and explicitly revealing an action possibility. This quality of interaction strategy can: 1) prevent users from making mistakes, 2) support intended user behavior by revealing hidden information, 3) lead to confidence in the choice of an action, 4) help users perform tasks in a more concentrated manner, 5) lessen the demands of the mental workload, and 6) enhance the user’s cognitive stage. These particular attributes of the concept lead to natural behavior and help people accommodate to everyday things, which outlines the importance of human-centric interactive design.

We have demonstrated the potential for feedforward to influence a user’s subjective time, perception of mistakes, and trust in the end. However, the latent potential of feedforward hasn’t been fully realized in the physical world. Much more research should be done to apply feedforward as an interaction design strategy. We should discuss power relations, the interpersonal relations between users and artifacts, the dynamic range of perspectives on feedforward and finally, how it shapes the experience.

Abstract

This paper details the evaluation process undertaken to create criteria for the development of an iPad stand for elderly users. Emphasis is on the requirements elicitation stage with end users in the field. 32 elderly participants taking part in the activity group as part of the Ageing-Well program of a City Council in a cosmopolitan area in Australia were part of an evaluation in which three existing iPad stands were trialled. While commercially available stands are abundant, specific problems such as reduced grip, basic technical understanding of the stand, and concerns surrounding stability were encountered within the group. Observation and semi-structured interviews were undertaken with the cohort to determine factors surrounding the suitability and uptake of these stands by elderly users – most of them with some disabilities - with findings suggesting that current tablet stands require fine levels of dexterity, which may not be appropriate for elderly users where such a device is needed. While usability in setting up the stand and use is a strong factor, aesthetics and material qualities are equally important for enjoyable use. In addition, the use of iPads in social activities between two or more older adults has specific demands in terms of visibility of screen, sturdiness and easy movement that is not considered by current tablet stands. The paper ends with proposing design recommendations. Further research is required to develop a suitable solution and refines these.

Keywords: iPad stand, co-design, older adults, usability evaluation, design aesthetics, case study

The research undertaken within this paper was part of a larger research project investigating mobile touch screen technology use in activity groups for older adults. We collaborated with a local council that is offering activity groups as part of their ageing-well program. Through this initiative, the council procured twelve iPads. While the primary focus of the research was an app development that is engaging for this target audience (refer to Pedell et al, 2013), the council staff was also interested with how to introduce, train and integrate the iPads into their group activities. In order to provide these groups with a useful experience and limit fatigue from using the product in a social setting (holding up the iPad for everyone to see the screen), tablet (iPad) stands are required. This holistic view is in accordance with other research which suggests that for the successful introduction of technology in older users’ life, it is not only the technology, but also the whole socio-technical system that needs to be designed and
considered (Waycott et al., 2012). In this case, this includes the social setting as crucial part of technology use in elderly activity groups (Pedell et al., 2013) and a suitable tablet stand.

Human factors, synonymously to Ergonomics (Sanders and McCormick, 1993) focuses on “human beings and their interactions with products, equipment, facilities, procedures, and environments used in work and everyday living. […] Human factors, then, seeks to change the things to better match the capabilities, limitations and needs of people” (p.4). Here, we aim to collect information on capabilities, limitations and needs in a field study with older adults in order to ensure realism and generalisability. Observations and evaluation are crucial methods in the design process for the creation of more usable interactive products (Rogers et al, 2015).

**Literature Review**

**Usability in older adults’ technology use**

Technology use in older adults is rising each year (ACMA, 2016) however, the design of technology and in particular mobile devices is centred towards able-bodied, young users. Technology, such as the iPad can promote social inclusion via applications such as video-conferencing, for example Skype, and increasingly, older adults are using social media websites such as Facebook as a way of keeping in touch with their families (ABC, 2017).

According to Allenby’s study, (as cited in McMurtrey, 2003), any new technology designed for an older person needs careful attention paid to the design of the display screen, choice of input device and the design of instructional materials and technical support systems such as help functions. Age-related changes in basic human abilities need to be acknowledged to ensure that the usability of the technology fits the capabilities of the user (Charness, 2009). These changes include the perceptual, cognitive, and motor systems of an older person (Fisk et al., 2009). In fact, according to Mallenius (2007), design should not be focused on age, but functional capacity. Considerations include decreased colour perception, difficulty hearing high-pitched sounds, decreased memory capacity and increased difficulty with fine motor skills. With these constraints in mind, designers can create better digital products for older people.

Specifically, this research project was designed to utilise the iPad to promote interaction within the council-run social activity group. One hindrance to the uptake of iPads that was found in this group was the perceived fragility of the device, due to its thin glass screen and aluminium casing and group participants’ hesitation to hold them or problems to hold them and use them at the same time.

There has been a lot of interest in recent research in the use of iPads for an ageing population. Advantages of touch screen tablets have been discussed by Caprani and colleagues (2011). Main benefits include (i) ease of use, (ii) mobility of the device, (iii) weight and (iv) flexibility in regards to individual interests (Simons and Kimberley, 2015; Hillier, 2013).

There had been not much research on the use of stands beyond product reviews (e.g. Fingal, 2013; Thiele, 2013) and to our knowledge no study has been conducted in which tablet stands are investigated on how use by groups of older adults can be supported by appropriate stands. While this is a lack for any user, it is particularly important for an ageing population. Even
though good stands are not tied to age (Hedge, 2013), age can be a variable that makes use harder (e.g. low vision, arthritis leading to less mobile fingers) for this user group. While such considerations are important, we do not want to fall in the trap of designing focussing on health deficit of the ageing population only. Pullin (2009) points out that designing with a deficit model in mind leads to design that can be stigmatising.

Aesthetics

Literature in the field suggests that the uptake of assistive devices can be hindered due to the aesthetics (Yeh, 2009); as the iPad has a very strong and iconic design aesthetic, the design of the stand should complement this and not take on the appearance of being something “assistive”. Ergonomics, as well as aesthetics should be considered in product design (Nunes, 2006). For example, the current homogeneity of wheelchairs is driven by ergonomic needs for people forced to be in a sitting position all day to support their spine. The similar look of wheelchairs results in a cover up of any individuality of their users (Barber, 1996). Similarly, developers of technology suitable for older adults put age first and ignore the diversity of this large and varied user group (Durrick et al., 2013). The majority of design surrounding ICTs for elderly users focuses on declining health, failing to provide appropriately designed technology and accessories to capable users or over-emphasising health issues. Design following a deficit model can often appear patronising to the user, where aesthetics are unattractive and stigmatise the users as incapable. Ideals of beauty and engaging use that are relevant to the ‘non-aged’ consumers are also relevant to the older users. Hekkert & Desmet (2007) propose all sensorial experience informs aesthetics and thus we include the material, tactile qualities surrounding product use in our investigation. We are not denying that older adults often do have physical constraints that prevent them in using certain products. However, what is proposed here is that this should not be the focus or the end result of the design to meet these limitations, as this often results in feelings and perceptions of stigma and consequently in non-use.

The objective is to provide an ergonomic iPad stand in the spirit of inclusive design that is aesthetically pleasing and at the same time caters for a range of capabilities, age and interests with a particular focus on how the stand can be used in group settings. While we speak in this paper of older users, the defining characteristic that drives our design and development is that it needs to be appealing to this wide range of capabilities, interests and ages as can be found in existing ageing-well groups.

In order to explore and understand user needs a study including a range of methods such as observations and group interviews was conducted. We aimed to find out what makes an iPad stand usable what aesthetic characteristics contribute to a positive user experience and how can materials support such an experience.

Context of the study

As part of a larger project in table technology uptake a suite of applications such as quizzes and games were installed on iPads, alongside custom applications that were developed for and catered to the specific demographic of the user group (see Pedell et al, 2013). However, within
the implementation of the technology, it was found that an inhibiting factor of the uptake was
due to the viewing angle, weight and physical orientation of the iPads. Many of the
participants were affected by physical constraints such as using one arm due to stroke,
immobility and reduced strength in wrists and fingers and limited eyesight. Literature that
involves studies relating to viewing angles of computer screens and interfaces (e.g. Hou et al.,
2012) suggests that viewing angles are highly relevant for good user experience (Bellman et
al., 2009) and health in order to avoid neck problems (Torsheim et al., 2010), but focusses on
single and often younger users (Myrtveit et al., 2014; Torsheim et al., 2010). Hence we
conducted this study to find out about what makes a good tablet stand for older adults in a
group setting to overcome these challenges.

Research Methods

Three commercially available stands were procured and tested with the group of older adults
in the council.

Procedure and participant sample

The trial involved 32 older adults participating in an activity group. Five researchers sat with
five groups of six to eight participants overseeing the activities and data collection. Larger
groups were seen as impractical as some participants had vision and/or hearing problems. Staff
members were assigned to individual groups to assist and encourage participation. Besides one
that had used and owned an iPad, the rest of the participants had no experience. They were
over 65 years old with the majority falling in the 70 to 85 year old bracket. We used a mixed
methods approach of semi-structure interviews and observations over the period of ten weeks.
The research team was visiting the group once a week for two hours. Initially, an observation
into the general physical abilities of older adults in the council activity groups in setting up the
stand was conducted. Then we explored how existing stands were used, were perceived and
allowed social interactions while using iPad applications. Lastly this was followed by deriving
implications for the development of a stand for different co-located activity group settings.

Chosen iPad Stands

In total three iPad stands were procured for evaluation with our participants. Observations in
former research have established that the standard Apple smart cover is not usable for older
adults (unpublished report by authors). The stand is difficult to set up and does not provide
sufficient stability during use (see Figure 1). The screen reflects so that it is hard for more than
one person to see the content on the screen.
From the vast amount of commercially available stands, the researchers chose three. They appeared promising in their feature set to be intuitive in their use for older adults and provide a high level of stability. We trialled three existing iPad stands: (1) Belkin Flip Blade Adjust, (2) Wallee X-Lock Kick and (3) Joby Gorilla Mobile Yogi. The following sections describe the main features and in more detail our decisions to use these particular stands for evaluation and a starting point for developing an iPad stand specifically for older adults in a social setting. A brief discussion about the key features of each stand is found below.

The Belkin Flip Blade (Figure 2) is made of aluminium and plastic with a spring-loaded mechanism. It has an ultra-slim design, which folds into itself for storage. Its dimensions when folded are 10 x 9.5 x 14.5 cm (L x B x H) and weighs 181 grams. It has the ability to tilt approximately 270 degrees. Thus, providing users with four adjustable positions by pressing two buttons in unison with one hand and rotating the rear support with the other hand. The Belkin does not have adjustable viewing angle. Even though it supports both portrait and landscape modes.

The Wallee X-Lock Kick (Figure 3) consists of a stand and case combination, whereby an angled metal bracket is locked into the stand thus providing a rotation function to the user. The mount is made of brushed aluminium and plastic resin for the case. Its dimensions is 16.5 x 7 x 5 cm (H x W x D). This stand is able to support both portrait and landscape modes. The
stand weighs 136 grams and the case weighs 68 grams.

![Figure 3. Wallee X-Lock Kick](image)

The Joby Gorilla Mobile Yogi (Figure 4) is made of polycarbonate and ABS plastic. The case weighs 147 grams and legs weigh 111 grams. It is also a case and stand combination. It comes with a pair of two highly articulated legs that bend in three dimensions. Due to the flexibility of the legs, this stand is able to provide users with countless adjustable viewing angles in both portrait and landscape orientations.

![Figure 4. Joby Gorilla Mobile Yogi](image)

Data Collection

Data was gathered via observations and semi-structured interviews during the ten group sessions. These sessions were recorded with video cameras. This was done in the five “natural” groups that were focus group sized, comprising six to eight older adults. The observations were undertaken during various stages of setting up the stands and user interactions – as individuals and a group, while using different applications on the iPads. During the sessions, the researchers focussed on the interactions with participants while taking notes on their immediate observations and the feedback participants provided. After all visits, a detailed
video analysis was performed using usability and ergonomic criteria for this analysis (Bevan, 2001; Nielsen, 1993).

**Usability of stand setup and use**

This stage investigated the necessary capabilities to set up different iPad stands. The three stands were given to participants with no instructions on their use and were told to set them up with the iPads. Assistance was only given when participants ran into difficulties. The observations of interactions with these stands focussed on grip, adjustability and general ease of use. As older adults were in groups, other participants would “throw in” suggestions or discuss their theories on how the stands work. Overall, participants were keen to trial these stands and would be cheered and clapped when process was successful. Researchers made sure that this was well-integrated as an activity rather than a rigid usability lab session in order to not put users under undue pressure. Participants would pass around these stands when they have had enough or succeeded and did not feel being under performance pressure. This was not only important to ensure participants were comfortable but also to take note on how much time they would give to a trial in real conditions (Duay and Bryan, 2008).

**Interview questions**

Questions during the interview focused on the user experience specifically on perceived efficacy, aesthetics and comparative analysis between the various stand designs. Questions in regards to the efficacy of these stands included:

- “How do you expect it to work?”
- “What do you like about it?”
- “What don’t you like about it?”

Questions were also asked regarding the products’ perceived aesthetic qualities:

- “How does it look like to you?”
- “How do you like the colour?”
- “How do you like the size?”

Questions on material qualities

- “How do you like the material?”
- “How does the stand feel to you?”

Particular emphasis was put on material as according to as Hekkert & Desmet (2007) it is important to include all sensorial experiences when considering aesthetic qualities and material is crucial to the tactile experience.

Once all the stands were evaluated over several sessions, participants were asked how the different stands compared to each other during use. Questions asked were:

- “Which one of the stands would you like to use?”
- “Which one is the easiest to use?”
- “Which one do you like best to look at?”
- “Which one do you think will last the longest?”
• “Any ideas for a stand that would be better than any of these three?”

Interactions with these stands were evaluated through observations, with particular care given to document the “unconscious” movements by our participants, such as group members huddling together when a stand was in use, versus the more private, single usage sans stand.

Also some video was taken and analysed in detail across the five groups and all visits. Not the whole visit was videotaped, but only sections of the visit. Focus of this analysis was on how users interacted with the stand or the screen and what impact this would have on the stand such as stability.

Data analysis

The interviews were transcribed and the researchers analysed words, meanings, themes and ideas provided by participants. A number of techniques were employed to analyse the interview data and the observational notes. Frequency of words related to participants’ perception and use of the stand were manually extracted and grouped to create a mind map. This was further analysed with use of the content analysis method according to Patton (2015) and thematic analysis was applied (Guest et al., 2012). Similar ideas and themes were grouped with the use of affinity diagramming (Courage and Baxter, 2005).

Results and Discussion

Usability of set up of and use of stands

Most of the participants had one or more physical limitations. The most common ones included mobility problems such as requiring a walking frame or cane, arthritis in fingers, inability to use more than one hand due to stroke, vision and hearing problems. All these physical limitations have an impact when using mobile touch screen technology and setting up of a stand. The three stands are discussed below:

Table 1. Comparisons of three existing iPad stands commercially available.

Belkin Flip Blade Adjust
One participant who had limited grip strength, remarked that this was “… hard to use with one hand, strong press necessary.” The stand’s mechanism was not as intuitive as the researchers initially thought they were. Even though participants watched each other operate this stand, some were unable to use it successfully. Several of these participants were only able to use one hand, due to various physical limitations, which increased the level of difficulties and subsequently leading to discomfort with this stand. However, overall it was well received when it was set up. One drawback of this particular product was that participants noted that there was a lack of adjustability in regards to the angle of iPad once it had been setup. Their
concerns were also around the main support piece: visually, it appeared too short for portrait orientation. Although, in reality, this stand is quite sturdy.

Figure 5. Testing Belkin Flip Blade Adjust stand with participants

The participants also expressed concerns with the quality of the mechanism, with one commenting that “... It should be spring-loaded – then it would last longer!” In regards to positioning the device in the stand, they were also concerned that the metal construction would scratch the shiny glass and aluminium surface of the iPad. However there is a layer of coating on the iPad that prevents scratches, although it is only found on one side. The other concern was that the iPad was very slim and it could slip out – several participants suggested that it should sit more sturdily within the stand (see Figure 5). In general, they felt that the unit should be one contiguous assembly where the iPad and stand were a single contraption so that it reduces the chances of misplacing either parts, “... not that the iPad is in the kitchen and stand is in the bedroom.”

Wallee X-Lock Kick
The Wallee addresses some of the main issues surrounding the Belkin stand; firstly the stand and case become one joined piece when assembled. There was a pre-defined list of angles and it looked to be a simple and easy to use product. However, it was the least desired out of the three tested. All participants as well as researchers and staff members realised that several difficulties presented themselves in the assembling process: (i) It was hard to figure out for the participants where to join the two pieces. One elderly lady expressed it this way: Like this? [...] Like that? Too high! Too high? No. Maybe the other side. No? Is it still too high? So, maybe this way. Too high! I give up! (ii) Even when the participants grasp conceptually how to assemble the two pieces several older adults got worried: That way yeah? [...] Ooop’s That’s it? Like that? Oh I am frightened. And I don’t want to break anything that’s not mine. A too high level of manual strength and dexterity were required in order to clip the stand into the case. In addition an older lady had poor vision and commented on the stand as follows: No. It won’t...It’s like putting the
tray thing in the microwave.

In order to attach the tablet to the stand, good eyesight was also necessary. Overall this stand proved to be a very difficult task for participants. It was very easy to make errors for most participants, alongside researchers, experiencing difficulties with assembling the product. When the stand was set up on a wrong angle, consequently, it would collapse during use what was experienced as even worse because users would get startled and were worried they had damaged the iPad. This stand also had the unwanted effect of scratching furniture. In two situations, (1) the supporting metal edge of stand was quite sharp and scratched the surface of a table even though it was hardly moved and (2) turning the stand toward another participant left a very prominent scratch mark; in the second case the user would not be able to lift the iPad as he had limited grip capabilities. When used with older adults limited grip strength or dexterity are common and a stand cannot be expected to be lifted. This particular stand could quickly lead to not only the furniture being damaged but even possibly causing injuries to the user. From a functionality point of view, participants did not find this stand to be as sturdy either as the Belkin when interacting with the screen.

In summary, the participants’ level of interest in this stand noticeably diminished after numerous attempts to set it up – again due to many of the participants having either limited dexterity or the usage of only one hand. This product was quickly ruled out as a possible solution. Other limitations include non-adjustable viewing angle and not being foldable. Nevertheless, this stand gave us valuable insights into requirements for an iPad stand.

Joby Gorilla Mobile Yogi
With this stand, connecting the case to the legs was reasonably easy, but not without faults. Most of the participants attempted to slip the legs into the case, but would realise then that there was a small toggle to be pushed for the legs to be clipped into. Due to the small size of the toggle, those with limited dexterity or eyesight found it difficult to operate this quite delicate element: *I can’t see it. [...] Like that? Where am I going? Like that? [...] I can’t see it. Have no glasses on. Oh. I’m not strong enough. Is that it?* While it was easier to assemble than the previous stand some participants gave up or handed over to others: *What? The clasp [...] I can’t do it. and Am I right that way? Oh. It won’t go in. It’s interesting.*

However, once it was set up, it rarely needed to be adjusted. Participants very much appreciated the stand’s stability and ease of use in regards to changing the angles even when only resting on one of the two legs during use (see Figure 6). In order to switch the iPad into portrait mode, users were required to physically detached the legs and re-attach them to another position. This was as discussed prior – a quite difficult task to achieve, but participants would receive feedback via the “click” of the iPad snapping in when they had completed this successfully.

Overall the participants were unconcerned when using the stand. One main advantage was seen in that it was not necessary to take apart the stand and once it was set up as it joined to one piece. However, the stand was easier to fold and pack away when compared to the previous stand. Participants found that overall it was a very usable stand and displayed great comfort in handling it. This stand was also the easiest one to change position to show other people in the
group content on the screen or to hand over. Neither was there any danger of the iPad falling over, falling off the stand or scratching the furniture. Some of the participants enjoyed bending and playing with the legs. One lady was twisting it right up and using it as a pretend microphone. The playful aspect should not to be underestimated and certainly added to a good user experience. The biggest discrepancy between interview data and observation data became apparent in what people said about this stand and the level of comfort in use they displayed. Some of the participants bent the legs around their own upper leg to use the iPad in her lap, but also to trial the grip of the legs in unusual positions. One participant was asked whether she was comfortable with the result responded: *Yeah. It’s comfortable like that. Very comfortable. You just have to put it like that.* However another participant commented: *I got big fat knees and my belly is in the way. No, it’s not comfortable.*

Overall, the Joby Gorilla Mobile Yogi was the most stable, easily to position and most versatile of the stands and handled the most competently by the participants. Unfortunately the manufacturer has since discontinued production of this stand.

**Aesthetics**

The most appropriate stand, the Joby Gorilla Mobile Yogi was deemed by the group to be unattractive and confusing to look at first. Aesthetically, this stand fared poorly as participants found that the uniquely shaped legs (which allow the stand to be positioned in a myriad of ways) to be unattractive or at the least very unusual. Hence the first reaction of many participants when looking at the stand was negative. This is interesting as other stands did neither receive a spontaneous positive response nor any negative response. This can attributed to the ‘Most Advanced, Yet Acceptable’ design principle popularised by Raymond Lowey (as referenced by Hekkert, 2006), where the design of the stand may be too far removed from the archetype, leaving the user uncomfortable with its aesthetic treatment and functionality.
Materiality
The group was also asked about their personal preferences regarding materials and weight of these three products and what they would like to see. Weight was a big issue in regards to the stands due to physical limitations of our participants. Hence a good grip was considered to be important. One participant felt that “… an iPad stand should be “light, not slippery”, with other participants (male group) feeling that it should be more about “… weight balance that makes them like a good tool.”

In regards to materiality, most appreciated the plastic covering as it inferred a level of protection and impact resistance to the iPad. Many participants liked the leather Apple “Magic Covers” of the researchers’ iPads, however they remarked that the angle was too shallow to be usable and that the magnetic locators were too fiddly and in one case it ripped off and fell. Hence, it was not chosen to be included in the formal evaluation from the start. The results were taken into account to propose a first set of recommendations for creating a usable and enjoyable iPad stand for older adults in social group settings.

Implications of results
A selection of stands was trialled with a group of older adults which despite being considered promising by the researchers originally showed minimal success when tested in the field with a real ageing-well group of older adults participating in a council program. Hence the findings suggest a new tablet stand to cater specifically for older adults in a social group setting is needed. The following recommendations are formulated around set up and use, aesthetics and material of a future stand:

Usability of set up:

1) The stand should be easy to assemble by older adults with varying physical capabilities including poor eyesight, single hand use and limited dexterity.
2) The tablet and the stand should compile to what behaves in use as one unit to avoid sliding, wobbling and disintegrating
3) There should be clear indicators via feedback (visual and acoustic) when the stand and tablet are securely assembled

Group use

4) The stand needs to be very sturdy during the interaction of one or more users in particular to strong pressure against the screen
5) The position of the screen angle needs to be adjustable to increase visibility for two plus users.
6) The tablet on the stand needs to turn easily without losing stability to be able to hand over the tablet for interaction to another group member

Aesthetics
7) Aesthetics is relevant and the look should carry a certain familiarity for the user. Materials
8) The materials of the stand should support a good grip
9) It should be constructed from a light material

These recommendations need to be detailed further in future studies. In particular in regards to aesthetics we merely received comments in regards to what people did not like in look.

**Conclusion**

This investigation highlighted the need for an appropriately designed and marketed tablet stand for older adults with varying physical capabilities in a group setting. As this study grew from a problem with researchers’ initial investigation – i.e. uptake of technology with older adults – it is apparent that for this demographic to engage successfully with such products, there must be considerations into the physical engagement and interactions with these products in use. While there are a myriad of stands available for iPads and other tablets, the problem is that none have been designed specifically for an older user demographic. The evaluation showed that none of the three iPad stands were ideal for the use of older adults in the investigated setting. This emphasises the necessity to further research the needs and attitudes of the elderly as well as what appeals to them in order to create appropriate solutions. First recommendations have been formulated to create an iPad stand which addresses the physical, but also the needs of older adults when using iPads in a group. Aesthetic and material needs require further research. Future research will create an iPad stand based on these recommendations which is regarded as preliminary high level guidelines for development. In a design process we will create the stand together with this group of older adults and will refine these recommendations in more detail to come up with formal guidelines.

Authors Biographies

Sonja Pedell
Sonja Pedell is Director of Swinburne’s Future Self and Design Living Lab, where her research contributes extensive knowledge of human-computer interaction (HCI) and research methods to the teaching of digital media and communication design. Alongside this role, Sonja is also Department Research Director for Swinburne’s Department of Communication and Digital Media Design. Sonja’s research interests include user-centred design methods, scenario-based and mobile design, domestic technology development, and the design of engaging novel technologies for various user groups, in particular for the ageing population. Sonja has received the Deans Award for Outstanding Researcher. She is the recipient of ARC, CRC and other grants. Prior to taking up these roles at Swinburne, Sonja completed a Masters of Psychology from the Technical University of Berlin and was employed as an Interaction Designer, Usability Consultant and Product Manager in industry for several years.

Jeanie Beh
Jeanie Beh graduated from Swinburne University of Technology with Bachelor and Master Degrees in Multimedia. She is currently a PhD student in the Faculty of Health, Arts and Design at Swinburne University of Technology. Jeanie is passionately interested in overturning the perception that older adults are unable or disinterested in developing skills in using technology. Her research focuses on ways to engage older adults with mobile touch
screen technologies through the role of human interest. Jeanie works as a research assistant at Swinburne’s Future Self and Design Living Lab. Currently, she is focusing on dementia related projects such as using technology to support social engagement while interacting with staff members, participants and their family members. When Jeanie is not doing research, she works as a freelance multimedia developer and designer. She has a year of experience teaching kids from prep to year 10 robotics and coding and almost seven years as a computer class tutor for older adults.

Gianni Renda
Gianni Renda is Deputy Director of the ARC Training Centre in Biodevices at Swinburne; an industry-linked and Government-funded PhD Training centre that focuses on industry transformation within the medical device industry. He is also a Senior Lecturer within the School of Design, focused on Industrial Design, Sexual Health and Assistive Technologies. He is heavily involved in community outreach in STEM education, mentoring groups of secondary schoolchildren in projects. Gianni holds a Bachelor of Industrial Design with Honours and Doctor of Philosophy from Swinburne University.

Emily Wright
Emily Wright lectures with the Design Factory Melbourne and the Communication Design Department at Swinburne. Her research focuses on human centered design, packaging design and design innovation. Her design practice career spans 20 years with work in publishing, branding, packaging and web design in the US, the UK, Mexico and Australia. Emily holds a Bachelor of Science from the University of Cincinnati and a Masters as well as PhD from Swinburne University.
Assessing a Rehabilitation Living Lab Research Project: The Meta-Analysis of an Inclusive Environment for People with Disabilities

TIIU POLDMA, SYLVAIN BERTIN, SARA AHMED, GUYLAINE LE DORZE, KEIKO SHIKAKO THOMAS

Abstract

This paper presents the results of a research based Living Lab experience, where people participate together as users, researchers, stakeholders and collaborators working to effect change to improve social inclusion and social participation for persons with functional difficulties. The Rehabilitation Living Lab in the Mall (RehabMall) transforms an urban shopping mall into an interdisciplinary, multi-sectorial research platform that supports multiple projects investigating what constitutes an accessible and inclusive environment for people with physical, sensory and cognitive disabilities. We present an overview of the RehabMALL Living Lab, the contexts of the project and the project meta-analysis to present the salient issues emerging from the projects that were done. Grounded in a design research approach, and inspired by the Ecological Systems Theory of Bronfenbrenner (1979), the investigations conducted focus on subjective and inter-subjective experiences within understanding obstacles and facilitators that frame how people experience going to the mall, and how the physical, cognitive and virtual environments that support these activities might be better served. Disability is defined within the framework of the “World Health Organization’s International Classification of Functioning (WHO, 2003). The overview of the project is presented with particular attention to the various collaborations and partnerships created alongside the issues that emerge in terms of results, and how people might be better served when public spaces are designed with their input and within a perspective of universal design.

Keywords: living lab, participatory research approaches, universal design, social inclusion, interdisciplinary approaches, functional difficulties

Living Labs are an innovative platform for doing research in the context of the urban environment, where co-design and research can come together to effect change. We present the results of an extensive research initiative done within a Living lab known as the Rehabilitation Living Lab/RehabMALL, the first of its kind in Canada. The Rehabilitation Living Lab takes place within both virtual platforms and the real physical environment of a commercial mall. The RehabMALL transforms an urban shopping mall into an interdisciplinary research platform that supports multiple projects investigating what constitutes an accessible and inclusive environment for people with physical, sensory and cognitive disabilities. The ultimate goal of the RehabMALL was to “create an inclusive environment that optimizes social participation and inclusion for all” (Kehayia & Swaine, 2016). This research project was lead by researchers with stakeholders including the owner of a Montreal downtown commercial centre Place Alexis-Nihon, “FPI Cominar”. We present what happens when a Living Lab becomes the catalyst for change, and when researchers work with stakeholders and industry professionals to change the conditions for access and inclusion for persons with disabilities using various forms of research
including design research. This project is the result of four years of investigation in collaboration with over 50 researchers and students.

We present an overview of the RehabMALL project and the overall results of some different studies undertaken during this four-year interdisciplinary, multi-sectoral project. First, the research is presented in light of the overall project objectives and subsequent application in terms of virtual, physical and technological solutions. Second, the lived experiences of persons living with disabilities are also presented. This aspect of the project was helpful within the RehabMALL work, as research was done early on and was influential in the decision-making that occurred in terms of physical changes made to the environment and in terms of how the mall changed to accommodate the emergent results and considerations that were provided to decision-makers on the renovation of the mall itself. Third, we present the meta-analysis of the entire project with an overview of the dynamics of the research project itself as a Living Lab, and including the collaborations and partnerships created to bring new knowledge and new forms of investigation. Finally, the discussion and conclusion present how the entire process was evaluated, what different research projects contributed, and what potential future initiatives have emerged.

The Context: The Rehabilitation Living Lab project objectives and process

The RehabMALL is composed of three main streams (as identified in the project overall objectives): 1) Identify the environmental, physical and social obstacles and facilitators to participation in the Living Lab space (for activities such as shopping or meeting with friends); 2) Development of technologies and interventions to optimize physical and cognitive function, social participation and inclusion of persons with disabilities; 3) Implement and evaluate the impact of technology, rehabilitation and design interventions in vivo in the Living Lab on physical and cognitive function, social participation and inclusion of persons with disabilities (Kehayia & Swaine, 2016: 1).

The research process is iterative in that it allows observation, creation and action with new reflections and actions from different levels and perspectives, and over several years. As a first step, it was important for the researchers to construct metrics of the existing situation and conditions, and identifying the factors that participate in creating optimal conditions for social inclusion in public spaces. The research methodologies included both quantitative and qualitative methodologies within different projects, and with the implementation of virtual and technological tools in vivo that can be developed and then be applied into practice. Several projects used a holistic approach centered on the person and their interactions with the environment, with the findings serving as a catalyst for the innovative tools and practices that ensued. The framework for these projects was the Living Lab.

The Living Lab Approach – Inclusion through rehabilitation and access

What is a “Living Lab”? The Living Lab is a methodology, an environment, a multidimensional and a dynamic system where people engage together to understand issues. This approach focuses on experimentation and co-creation, with the real users of environments, and where all stakeholders collaborate together to discover new solutions, new products and new services (European Network of Living Labs, ENoLL; Ahmed and al., 2015). The Living Lab operates in a
real context within public-private partnerships and integrates various researchers from different disciplines. It makes the real world a platform of interaction for experimentation, research and design. In light of this approach, the following questions guided the framework of the lab: i) How to increase the quality of public spaces for people living with disabilities? ii) What are the facilitators and obstacles that help or prevent persons with disabilities to access a commercial centre? As Living Labs are somewhat organic in nature, the overall project was structured to provide cohesion and guide researchers as they developed their projects.

**Focus on user experience: Physical, Psychological, Social and Virtual Reality in the RehabMALL**

From a theoretical perspective, the project espouses a holistic approach centered on the person and its interactions with the environment. It includes the relation with oneself, the body, the other persons, the physical environment but also sociocultural aspects of the environment such as society values and ideologies. Inspired by the Ecological Systems Theory of Bronfenbrenner (1979), the investigation focus on subjective and inter-subjective experiences. It understands the relation with the environment as participation and interaction with the society. Disability is defined within the framework of the “World Health Organization’s International Classification of Functioning”, that means it considers disability and health as a complex physical, cognitive and social phenomenon (WHO, 2003). Therefore, it helps in understanding the link between individuals, participation, body structure and functions, and environmental factors.

Many studies were conducted in the RehabMALL to explore and assess the usability of the mall (Swaine et al, 2014; Kehayia et al, 2014; Poldma et al., 2014). Early projects explore the social and physical environment of the existing commercial centre, the facilitators and the barriers that users with disabilities encounter during their experiences when frequenting the public spaces of a mall. These projects included diverse studies on users’ perception using participatory research with walkabouts and “in situ” discussions with various stakeholders and individuals living with disabilities. The data collection included focus groups, participant observations and informal discussions alongside lived experiences in the walkabouts around the public spaces. Some participants were engaged over the four years of the data collection with walkabouts both before and after changes were implemented in the mall. Furthermore, stakeholders such as the owners, mall administrators, shopkeepers and vendors were invited to participate to the research. Specific questionnaires were developed for participants with particular diseases and/or disabilities and specific aspects of rehabilitation, including the entourage of persons with disabilities such as caregivers and parents.

In terms of design research, some projects explored the “psycho-social” and “physical-social” elements of the mall. Both physical characteristics and the social activities that occur as people navigate the mall were documented (Poldma et al, 2014). Existing characteristics on site such as circulation pathways, physical surfaces, lighting, colour and materials and noise levels were documented to provide a portrait of the existing obstacles and facilitators within the public spaces. Furthermore, researchers documented the issues faced and what design elements support or hinder access, social participation and active inclusion in the everyday activities of people. Here in Figure 1 we see a typical view of the public spaces at the beginning of the project.
In another comparative study of the environment before and after renovation, the physical changes of the mall and the impact on user experience were documented as well as documenting how the renovations impact on people’s lives. In yet another study, the universal design and way-finding elements in the mall were examined in light of how information is understood. This study included a post-evaluation of the physical environment, recommendations for signage, way-finding and how information is read by people navigating the mall.

Once design changes were made, the researchers returned to the mall to conduct a post occupancy assessment, a tool used to record both physical changes and to understand the users’ satisfaction post renovations to the existing public spaces. This tool enables studying what impact these changes have on well-being and social inclusion. As Poldma notes: “The Post Occupancy Assessment is a tool used in design and architecture and is a standard tool for documenting user satisfaction post-building construction. This form of assessment is used also to evaluate user satisfaction in different types of interior environments.” (Poldma et al., 2016: 2). Here in Figure 2 we see the interior space of the mall after renovations.
Co-creation and virtual reality

Furthermore, many of the 45+ studies undertaken during this investigation addressed the needs identified in objective 1. As Kehayia & Swaine note, project research included “…co-creation of simulations of the mall environment using virtual reality (VR) to train navigation in a secure laboratory setting before entering the real mall environment” (Kehayia & Swaine, 2016:2). Tests were conducted in virtual/laboratory environments. For example, tests evaluated new measures designed to study sensorimotor integration for balance and mobility enhancement, thus preparing individuals with disabilities before they actually go to the mall. This research simulated different environments, developing software and testing new techniques to support rehabilitation with the simulation of real environments. For example, geographic overviews help participants to plan their trip and allow for “virtual travel” before or during the real-time experience. In another example, global positioning systems (GPS) were used to help navigating within the mall, and special modules were co-created to train individuals with cognitive limitations, post traumatic brain injury and/or stroke. Projects were for visual, auditory and language challenges (language process and visual-linguistic interaction) and Communication Enhancing Systems were developed in both in laboratory and real environments. In Figure 3 we see a simulation of a person testing their reactions within a simulated virtual environment:

Figure 3: Virtual shopping demonstration at the mall by researcher T. Weiss

RehabMALL as collaboration and partnership: A Community of Practice for co-construction and sharing knowledge

This project was a massive undertaking that included multiple researchers, stakeholders and collaborators. As a people-driven project in an exploratory environment of the MALL, the project required structures to support the interdisciplinary, international and multi layered participation that occurred. First, researchers participated from many universities in Quebec and Canada, and from countries such as Israel, Italy and the United States. Collaborators and partners included the users with disabilities themselves, who come largely from the local and surrounding community. In this holistic perspective, researchers come from diverse disciplines as sociology, anthropology, design, architecture, engineering; partners come from different sectors as
development, retail, rehabilitation, industry, academic (Bertin et al., 2013). Second, in terms of communication and process, each study included valuable information, providing recommendations and guidelines for the mall administration, the architects, and other decision-makers in the public-private dyad. Thus fundamental knowledge changes the design of the mall renovations made with a universal design approach in mind and considering the research done to date.

**Engagement and partnerships as a driver of change in the Mall**

In terms of the mall interior, some visible changes made during the renovation of the mall included: 1) the addition of an access ramp giving direct access from the subway station to the mall; 2) a new centrally located elevator; 3) new signage design and implementation; 4) new lighting and new materials and furnishings throughout including seating areas. Furthermore, extensive work was done in the garage and at access points to the mall to facilitate parking and arrival at the various levels.

The partnership between researchers, engineers, architects and administration rendered the mall more accessible overall and the design provided new places for congregation and activity on each level, an element deemed necessary for affording social inclusion. There was an overall increase in the use of the mall by people with disabilities, as traffic patterns studied indicated an increase in the traffic of older persons at some entrances, from the existing 6% to 23% (Kehayia & Swaine, 2016).

The Living Lab approach resulted in easier access, changes in attitudes, new and strengthened partnerships and increased engagement. First, changes made to the mall had a positive impact in terms of providing easier access for various people with disabilities. It also changed attitudes within the mall and among stakeholders. Second, the partnership raised awareness about the importance of taking into account the needs of people with disabilities, which can positively contribute to change culture and perspective in creating inclusive environments. Finally, this approach led to increased community engagement and this had a positive impact in terms of its influence on the process of the investigation, on the methods and indicators used for assessment of the project, and on the multidisciplinary collaborations that developed between researchers and practitioners. The multiple projects brought new understandings about community concerns, about different levels of intervention and about what is needed when rehabilitation patients integrate back into society. The added creation of the CoP virtual platform facilitated discussions between stakeholders on important mall-related topics such as public accessibility issues, community needs to optimize social participation and inclusion, and the setting of research priorities.

A bilingual website was also created to facilitate communication and inform the general public. Annual meetings have been held since 2011 bringing together 70 stakeholders, partners and team members together with the Advisory Committee who provides oversight. Events such as the Scientific and Open House Day (2015) held at the commercial complex itself, provided a real time experience within the venue of the mall, showing an overview of achievements and results of the research to various representatives, affiliated universities, general public, shopkeepers, members of the Living Lab, researchers, students and government officials.
Community of Practice

As mentioned, an important element in the structuring of the activities was the Community of Practice (CoP). As a concept, communities of practice are a loosely organized group of people with common interests who meet to engage in the issues of importance to them. CoPs are an important facilitator in an evolving participatory research approach and in the case of the RehabMALL, the CoP helped to frame the issues facing the project and the various ways that stakeholders participated. CoPs encourage creativity and innovation by bringing knowledge profusion, multiplying perspectives and combining different research fields. Furthermore, CoPs prevent the division of the stakeholders, helps to prevent duplication and make it possible for all the partners to be part of the project (Poldma et al., 2016). The Community of Practice had an impact on individuals and on organizations by facilitating the vitality of exchanges, communication modes and members’ satisfaction. Participants were encouraged to raise new subjects, to make comments, and to explain their ideas in a collaborative environment of exchange. They also get a better understanding of the different aspects of the projects and how they can contribute to it. The CoP offered an opportunity to exchange information with people in a related domain, speak about their own experience, and see the advantage of working with similar organizations. Globally, participants were satisfied with CoP exchanges and the virtual platform that accompanied the CoP meetings and exchanges.

A Meta-Analysis of the RehabMALL Project: The overall assessment five years later

The meta-analysis was conducted to study the overall impact of the research studies and the implementation of innovative technologies, social programs, programs to raise awareness, physical changes of the environment, and development of new tools. After five years, over 60 research projects have been conducted with the participation of over 55 researchers. Also, at the end of the project life, it was essential to evaluate not only the results of this project but also the outcome of the process and the impact of the research done, for future continuation of other initiatives, and to understand the real impact of the research on changing the environment on multiple levels. It is important to both understand the results from a holistic perspective and to question the process of the RehabMALL itself, for the development of new research. As Poldma noted:

“The Rehabilitation Living Lab requires both a post-mortem of the research and renovations done to date, and a meta-analysis of the entire Living Lab project at this stage. Questions to be asked include: What are the processes and impact of the research carried out by the PSI Mall project to date? What is needed to address gaps in interventions and outcome evaluation to continue to evaluate the implementation process and impact of the mall “Living Lab” physical changes and the various research programs? Furthermore, issues such as stakeholder involvement and user experiences have been documented at least partially but not analysed in the context of policy.” (Poldma et al., 2016)

The focus of this meta-analysis was the evaluation of the process and the impact of the MALL project. From a methodological point of view, it was important to analyse the impact of the changes made within the physical environment, understanding the diverse investigations to synthetize their results, all the while considering the “Living Lab” both as a phenomenon as well as a meta-project that provided the support for a variety of research projects and initiatives.
The use of the Grounded Theory (Charmaz, 2006; Glaser & Strauss, 1967) assisted in the data collection process of the different research projects for the meta-analysis and for providing the overall framework developed for the data collection that ensued. As the researchers involved in the meta-analysis noted:

“This phenomenon can best be assessed with grounded theory methods, wherein the phenomenon is studied “from the ground up” and considers the elements of the project in terms of sifting the data collected to glean a complete picture of the research done to date (Glazer & Strauss, 1990; Charmaz, 1988). We are interested in discovering what has happened, how the research projects have influenced the outcomes in the MALL, and how the MALL has influenced the research undertaken…” (Poldma et al., 2016: 3)

Four researchers evaluated the entire RehabMALL with five different perspectives (projects) that were conducted within the meta-analysis framework. These included:

1. The Precede-Proceed Model;
2. The Physical Post-Occupancy Assessment of the RehabMall;
3. A comparative study of the accessibility of the mall relative to the International Classification of Functioning, Disability and Health (ICF) criteria;
4. The assessment of relative increase in satisfaction and social participation;
5. A policy analysis.

**Discussion: The emergent results of the studies within the Meta-Analysis**

As per the perspectives, we present the summary of five studies conducted within the Meta-Analysis and their results:

1. **Precede-Proceed Model (Sara Ahmed):** The PRECEDE-PROCEED model was applied as a framework for the implementation and evaluation of the project performance over the course of the entire five years (Green & Kreuter, 2009; Ahmed, 2014). It is a participatory planning model often used to evaluate public health programs. It meets planning, implementation and evaluation aspects to provide a framework for activities (Ahmed and al., 2015). The model presents the pre- and post- research goals and objectives and compares the results of the research and the Living Lab changes. The PRECEDE-PROCEED Model (PPM) was applied to existing mall setting and was used to develop a framework for an inclusive environment. It meets consumer, participation and social needs of persons living with disabilities. According to Sara Ahmed, leader of the PPM: “The PPM provides the blueprint for the construction and evaluation of health programs in nine steps divided between the planning components (phases 1-5), implementation (phase 6) and evaluation components (phases 7 to 9) (Crosby & Noar, 2011). Use of such a framework for the MALL project was considered important to promote the transferability of the process to other similar research environment and national and international programs.” (Ahmed and al. 2015b: 3-4). The model is composed of nine steps divided in two phases. The first phase “PRECEDE” deals with the planning, the assessment of the community, the user needs (social and epidemiological, behavioural and environmental), and the development of intervention programs (educational and organisational diagnostic, administrative and policies assessments). The second phase “PROCEED” deals with the evaluation, which corresponds to the implementation of activities and programs (including technologies and interventions in vivo), and to the processes,
impacts and results assessments. The model enables to identify and fills the gaps on different aspects that emerged: the general conditions outside the mall and inside the mall, the social support, the education, the society/policy, and the person (Ahmed and al. 2015).
