2- The Physical Assessment of the mall environment and Post Occupancy analysis (Tiiu Poldma): The post-occupancy evaluation assesses users satisfaction after the design and the changes made due to the renovations made physically to the mall. A content analysis of visual elements was also conducted to compare the quality of the environment both before and after the renovations. Parallel to the documenting of the physical changes, people’s experiences were documented with walk-abouts that were conducted with individuals living with disabilities (Poldma & Herbane, 2016). Narrative of these experiences included comments about the changes made, and the different elements of the environment. Emergent themes included characteristics such as ramps and access points, circulation, overall accessibility, equipment, services, signage and whether or not social inclusion was successful. Before the renovations, some elements were absent, such as useable access ramps, railings and signage. Some problems identified included the lack of luminosity, difficulty in reading the space cognitively, lack of floor markings to help visually impaired persons to identify obstacles, among other issues. Changes made included the installation of two access ramps and an elevator in the central core of the public spaces, reorganizing the information booth to the central core, the design of new signage, the increase of luminosity, changes to the material choices, the improvement of visual conditions, and better space organisation with wider aisles for easier circulation. Finally, while most participants made positive comments, social inclusion concerns remain. Users with disabilities often need help, and they feel degraded when they have to ask or to wait for help. Some people can be curious and ask questions, other just let them do what they want. There is still work to do on the social level to raise awareness and to inform the general public on the interaction with people with disabilities, to counteract these types of stigmas.

3- Comparative Study of the accessibility with the ICF criteria of the World Health Organization (Geneviève De Repentigny Roberge): The International Classification of Functioning, Disability, and Health (ICF) defines various aspects of disability: physical, mental, functional and environmental (De Repentigny, 2015). The analysis conducted post renovation was done to compliment the post occupancy evaluation. This analysis compared the accessibility and its relative success with the ICF criteria. Issues emerging from this study include the following: a) The products and the technical systems can facilitate or create a barrier to communication. Some elements such as access ramps, elevators, signage, the information booth, and the indication of services help the navigation and the way-finding. However, the lack of access ramps, lack of clear visibility, automatic doors, fountain and seats that are easily accessible, all contribute to limitations. Specifically, problems with signage included high and far locations, a limited access to needed information, and an overall lack of signage available at lower levels constitute obstacles. b) The physical environment includes people in movement, light and sounds all together. These elements worked together better in the new renovation, as in the existing conditions the lack of luminosity, the presence of shadows and the high level of traffic constituted obstacles. c) The social environment corresponds to the help that family, friends, other users, community members, guide-dogs from associations for the visually impaired (such as MIRA in Québec, Canada) and assistants can give to individuals with disabilities. And while the central relocation of the information booth helped to create a clear place for people to ask for
help, conversely several people noted that the personnel at the information booth was not trained to help persons with disabilities. d) This study also reviewed the attitudinal environment, as per the ICF - this refers to attitudes people have when they are around individuals with disability. This may include family, friends, health-care assistant, users, and so on. Despite the many positive changes made to the mall, some disparities still exist depending of the type of deficiency (visual, motor, language) of the person navigating the mall. There is still work to do to change perceptions and to encourage people to be more tolerant towards different persons. e) While specific services, systems and policies were not studied extensively before the changes made to the mall, some issues did emerge, such as the need to have Internet access and to have mobile applications to help people with disabilities to navigate and find their way within the mall.

4 – The assessment of the increase of satisfaction and social participation (Guylaine Le Dorze and Geneviève de Repentigny Roberge): An analysis of the satisfaction and social participation was conducted to understand how these were affected by two elements: environmental factors and lived experience (Le Dorze & De Repentigny, 2016). The environmental factors include attitudes, help, relations, and the physical environment. The researchers analysing the mall post renovation considered the visibility, the use, the comfort, the positive and open attitudes, the patience and the support of people in the mall, and the presence of pets. An adequate environment helps orientation, visibility, use and comfort. Also, the question of “sense of safety” is important and is tied to the social aspect of coming to the mall and meeting someone, not hampered by these types of concerns. Overall the mall satisfied people for these perspectives, as many stated they were happy to come to the mall whereas before they were not as comfortable due to issues that hampered an increase in satisfaction and social participation.

5– Policy analysis (Keiko Shikako Thomas): An environmental scan and a series of assessments with focus groups were done to analyse the different phases of the project from the perspective of social policy (Shikako-Thomas and al., 2016). The main objectives were to identify actionable policy points from the mall and policies that can impact on individuals living with disabilities. The goal was also to develop a framework to transfer knowledge between research and policy. A participatory research segment was conducted to analyse existing policies. The framework was based on selected social determinants of health in Canada (such as income, education, unemployment, job security, etc.), environmental and social factors, and life style. Specific documents analysed included the UN Convention on the Rights of Persons with Disabilities (2016), priorities listed from the Provincial Office for Disabled Persons (Office des Personnes handicapées du Québec, OPHQ) and some components of the provincial laws (Quebec Law E-20.1) that support the social integration of persons with disabilities. Focus group and interviews were done to understand the issues and to structure potential policy strategies. Concerns that emerged included: the need to go beyond policy charts, strategies to engage stakeholders in the research to policy dyad, ethics of applying research to practice and the need to include other vulnerable populations in social spaces (Shikako-Thomas and al., 2016). Overall, it is determined that integrating research information with policy guidelines and research policy facilitates participation of individual with disabilities in society in general, and at the mall, in particular. Encouraging stakeholders in disability to inform research and policy through continuing collaboration supports rehabilitation research with policy impact and is vital to pursue.
Conclusion

This complex and large investigation had many potential, intrinsic challenges. The first challenge was to assure transparency and flexible management of communication that changed the management culture of the commercial centre. The second challenge was to ensure that user needs are central to research. The third challenge was to work in an environment such a commercial centre where public and private interactions are dynamically occurring. Finally, the fourth challenge was to connect the healthcare system perspectives and needs with those of a commercial centre.

The project has had an enormous outreach on multiple levels including researcher recruitment, student training, involvement of the general public and the clinicians milieu, training of highly qualified personnel, diffusion and publication of knowledge, organization of conferences, technological innovations, and more (Kehayia & Swaine, 2016). Furthermore, this project expanded the comprehension of the lived experience of users and especially in terms of the context where these conditions are experienced. The project also provided recommendations for health care providers and community organizations. The RehabMALL provided a new platform for reconsidering intervention planning with the organizations involved and how the collaboration, of both the different partners and the collaborators, was vital with the shared desire to create a more inclusive society. Furthermore, the project documented different research processes, and developed a variety of assessment tools and cross-disciplinary collaborations. It developed a virtual platform to encourage and facilitate communication – the community of practice (CoP) and various projects provided technological tools. Globally, the project had a positive impact on collaborative work and helped create the feeling of taking part in a community. In turn, this community feeling enabled a shared leadership, raised mutual trust and autonomy, generated creativity and innovation, while offering continuing training opportunities and stimulate reflection (Poldma and al., 2016).

The impact of the project was substantial in terms of research and the resultant accessibility of public spaces. Research informed renovations that in turn improved the circulation, the perception, the orientation and the way-finding for persons with disabilities who come to the mall. In terms of universal standards, the access ramp and the elevator facilitate the passage from the metro station to the commercial centre and the street level, while circulation changes facilitated movement within the mall. Way-finding was facilitated by both spatial changes and signage changes. The project integrated research within the decision-making structure of the shopping mall and in doing so, built new forms of collaborations and research.

The project made the public spaces more inclusive and opened to people living with functional difficulties. It encouraged administrators, researchers and health care professionals to change practices and to reinvent ways to transfer knowledge from research to the professional milieu. In the end, it essentially demonstrated the need to persevere in designing inclusive environments to fulfill universal design needs in society.

Paper Title: Designing One-flat church as small-scale community space in densely populated urban environment to perform both sacred and contemporary functions

Dr Louis Poon Shek Wing, Senior Lecturer of Interior Architecture, Department of Design at Caritas Bianchi College of Careers (CBCC), Hong Kong, lpoon@cihe.edu.hk / louisswpoon@hotmail.com

Abstract

This research is based on the scenario in the context of Hong Kong, in which church has been built in densely populated urban environment restricted in flat space. The research objectives were: 1) firstly to investigate the relationship between theology and spatial design in Hong Kong Protestant church; 2) secondly, to analyse the issue of the lack of design with respect to sacred identity in the church of Hong Kong that leads to an unappealing and non-sacred appearance of Protestant church; 3) and finally, to establish theoretical standpoints on designing sacred space with contemporary quality without surrendering of the sacred identity. The aims of the research were to understand the influence of secularisation to the rationale of church design and to generate an appropriate identity of church with a theoretical standpoint to serve the contemporary community effectively.

In order to meet these objectives, the study comprised of a qualitative site observations of 171 churches, which provided comparative figures for the study of churches incorporated with design elements or no design elements.

In Hong Kong approximately 775 one-flat churches, which are 66% of the total number of Protestant churches, are located in different layers of vertical space within this vertical city. When churches provide social services in the same limited space, the identity of church is surrendered to the need of the social community.

This study endeavours to facilitate church design with the focus on the immanence quality in order to encounter the different spatial limitations in church design.

Keywords: Church design, Community space, secularisation, sacred and profane, contemporary design

Historically, church architecture is a spiritual and sacred space people could experience the solemnity and serenity. Due to secularisation, in Hong Kong, the scenario of one-flat churches has been shifted to unappealing and non-sacred appearance. With approximately 803 one-flat churches, which are 62.4 % of the total number of Protestant churches, they are scattered among different buildings that function as small-scale community space.

The phenomenon has become worse when churches operating social services in the same venue; the domination of the social community towards the sacred community has
hidden the church identity. Churches simply surrender the sacred identity despite there is multi-functional scheme to transform the space from the profane to the sacred uses. Despite implementation of church design has been adopted progressively, the sacred identity is forfeited because of their focus on attracting newcomers with a contemporary looking church. These two approaches have overlooked the significance of church as the house representing God. The discussion of representing the transcendence and immanence of God was one of the vital concepts relevant to one-flat church design. When churches are small in space, the representation of the immanence of God is more appropriate. Torgerson (2007) commented that “the transcendence of God was on decline, and the immanence of God in people was highlighted” (p.12).

As a researcher with background in interior design and pastoral ministry, there is a desire to contribute the knowledge and experience to conduct a research which could generate a deeper reflection in church design related to urban context. It was hypothesised that designing church as a small scale community space in densely populated urban environment requires to put a balance between community need and sacred identity with the application of contemporary design. The key research question is: How to design one-flat churches with physical constraints and multi-functional needs while preserving sacred and contemporary qualities simultaneously?

**Literature Review**

**Secularisation and Church Design**

It is vital that, in Western church history, church design was always associated with theology and aesthetic manifestation for the representation of the Deity. The scenario after secularisation with the merge of the separation of the sacred and the profane into a continuum which resulted in the loss of sacred identity. And churches rather put their focus on contemporary quality indeed. When churches were further challenged by secularisation to try new ways to express their faith, they surrendered the sacred identity in order to break the threshold fear.

We cannot change this reality, then it is a matter of how to embrace it. Bruce (2002) shared similar approach with Cox. He quoted from Fallding (1967) the saying that: “What modern man would need, if he chose to hold on to religion, is not to turn away from secularisation but to baptise its fruits, grafting each innovation back onto the tree of his life and consecrating them all to the service of the whole” (cited in Bruce, 2002, p.359). Theologian Tillich and Bonhoeffer also acknowledged this attitude and their writings contributed in-depth discussion on this theme.

Renowned theologians, such as Dietrich Bonhoeffer (1930/1963) and Paul Tillich (1987) expressed the need to find a contemporary approach to reach out to the world. As Bonhoeffer contested, churches were encouraged to develop a secular manner to deliver the message. Hence, a contextualised attitude was essential and Bonhoeffer stated that “we can now let go and immerse ourselves in the new world of the secular city” (as cited in Cox, 1966, p.18). In their modern context under all the challenges, their perspective was that secularisation did not necessarily pose a negative impact to Christianity. Under the conviction that church design must be contemporary and responsive to the need of the age, different scholars such as Hammond (1960); Bruggink & Droppers (1965); Smith (1964); and Kilde (2008) delivered insightful ideas about contemporary expression. When scholar
like Kilde (2008) wrote about this issue, he tactfully referred to renowned Catholic theologian Thomas Merton that “contemporary faith required a contemporary architecture” (p.162).

Definition of Sacred Quality in Design

One of the aims of this thesis is to incorporate both contemporary and sacred qualities into church design. Could contemporary quality co-exist with sacred quality? Apart from defining contemporary quality in the precious section, it is necessary to define sacred quality as well. It is essential to clarify that the discussion on sacred quality here is about design elements to achieve the sacred effect.

Pichard (1960) identified sacred quality as the expression of mystery, magnificence and splendor which are qualities associated with Medieval churches. Kilde (2008) pointed that, “the desire to project a single, unified image of Christianity in a context of increasing secularisation and denominational fragmentation” (p.165). The rationale of some church leaders was that sacred quality should be different from secular design and because contemporary design was associated with secular design, some church builders rejected contemporary quality and followed Medieval style to present the sacred quality. In Pichard’s opinion, he did not reject contemporary approach but his idea was that simplicity as associated with contemporary quality was opted to link with grandeur in order to achieve the transcendent effect. However, one flat churches in Hong Kong under site limitation are difficult to deliver the transcendence of God; discussion is needed to explore whether the search for sacredness should be targeting on the immanence side.

Hong Kong Church Design

Let us conduct a historical review of Hong Kong church design -- From Western to Hong Kong Church Design: Church growth in relationship with the Use of Space from Individual Building to the Unique Scenario of One-flat Church in Hong Kong.

From 1842 onwards, Protestant Church of different denominations and missionaries organisations started to establish churches, schools and hospitals in Hong Kong. In 1950’s, because of the influx of refugees from Mainland China, the number of churches began to grow steadily. (See Table 2) Due to church planting movement, Church growing rapidly from 1980’s to 2004 (From 1842 to 1979, 538 churches were established; up to 2004, there were 1181 churches — a multiple number of churches was planted within these 24 years). A total of 1,287 Chinese-speaking churches were surveyed in 2014, there were a total of around 305,097 church members in Hong Kong (Wu & Lau (Eds.), 2015, p. 17), and they distributed among more than 50 denominations together with more than 200 churches without any denominations. From table 2.6, 80% of churches in Hong Kong with congregation size was less than 200 people. Majority of one-flat churches was located in limited area with smaller size of congregation. Until 2014, there were 687 churches (53.4%) located in residential buildings, commercial buildings, 100 churches in social services centres and 303 churches in schools (Wu & Lau (Eds.), 2015, p.13). A total number of approximately 1126 churches was located in non-individual church buildings. The high proportion of churches without individual church buildings was a very typical and unique phenomenon in Hong Kong because of its scarcity of land which would make individual church buildings costly.
Churches were located in multiple layers of vertical space in a vertical city. Because sites such as ground floor shops in busy areas and multi-level shops with double height spaces are relatively expensive, churches generally occupied flat spaces upstairs in commercial blocks or residential buildings, especially in busy urban areas. (See figure 1) In one case, it consisted of seven churches located in a commercial building in Shatin.

Figure 1: One-flat churches in different layers of buildings

Social Need Influenced the Secularisation of Hong Kong Church as Small Scale Community Space in One-flat Church

The prominent role of the church was to serve the community, in addition to providing worship space to the public. According to Wu and Lau (Eds.) (2015), around 66% of churches provide social services; which was a significant increase as compared to the 1999 survey which was around 41.5%. There were around 849 churches providing social services (p98).

Participation in social services was a dominant strategy for churches. However, it terms of design, it is discovered that churches surrender the sacred identity to the identity of the social services. On the other hand, in order to reach public housing residents, church organisations applied for the establishment of the affiliated social services centres. During weekdays, the centres required to fulfil the requirement of the social services as granted by the government. The spaces were then converted into church spaces on the weekends. Apart from subvention, majority of churches ran their social services on self-financed bases; hence restrictions from government could be reduced; and flexibility in design approach and spatial arrangement could be enhanced.

Statistics of Hong Kong Churches Surveyed in 2004

The statistic is extracted from the book 2014 Hong Kong Church Survey – The collection of statistical Data edited by Wu, C.W. & Lau T.H.

A total of 1,287 Chinese-speaking churches in 2014.

- There was a weekly average of 305,097 Christians attending services.
- There were 560,547 registered members (both overseas and local); 327,112 members in Hong Kong.
- 62.4% of churches were located in flat spaces, such as residential buildings, commercial buildings and church operated social services centres.
Table 1: Distribution of Churches in Different Kinds of Worship Places:

<table>
<thead>
<tr>
<th>Kinds of Worship Places</th>

<td>Industrial Building or Centre</td>
<td></td>
</tr>
<tr>
<td>Others</td>
<td>96</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>1056</strong></td>
</tr>
</tbody>
</table>

There were 803 churches located in different levels of high rise building, such as commercial buildings, residential buildings and public housing complex. There was a rising number of churches situate in school due to the opportunity of evangelising in church operated school which could reduce cost in church planting as well. There was a drop in number for churches in social services centre but the number of churches provide social services is 849 which was 66 percent.
Table 2: Distribution of Churches with Different Sizes of Congregation:

<table>
<thead>
<tr>
<th>Sizes of Congregation</th>
<th>No. of Churches</th>
<th>Percentage (%)</th>
</tr>
</thead>

<td>34</td>
<td>2.6%</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>1181</strong></td>
<td><strong>100%</strong></td>
</tr>
</tbody>
</table>

From Table 2, it is found that there was 69.7% of churches with size of congregation below 200.

**Research Methods**

Qualitative method through field works are applied to understand the subjective meaning of behaviours and the phenomenon of the spatial settings. In applying qualitative research methods, the researcher has conducted site observation of 171 churches. The researcher has obtained better understanding of the scenario of one-flat churches in Hong Kong. Seven churches have been selected to conduct site observation with long term participation in order to identify with the needs of the spatial arrangement and the users. Under site observation of selected churches with long term participation, the researcher has also participated in different activities organised by the seven selected churches. Even though the researcher does not use participant observation, it is vital for the researcher to act as a worshipper to obtain first hand experience about worshipping in specific settings. Hence, valuable insights can be gained as an insider to evaluate the findings, which echoes with Corbetta annotation about ‘vision from within’ in particular.

**Site Observation**

From site observation of 171 churches out of 1287 churches in Hong Kong, these Hong Kong churches were classified into four categories under the division of sacred quality and contemporary quality, the relationship of theology and spatial design was then discovered explicitly. *(The term sacred quality refers to the presence of symbolic meanings; the term contemporary quality refers to the presence of contemporary interior features.)* Majority of churches which employed designers are creating a contemporary
quality without strong awareness of the sacred quality.

Table 4.1: Scenario of Church in Terms of the Representation of Sacred Quality and Contemporary Quality

<table>
<thead>
<tr>
<th>Sacred quality</th>
<th>Contemporary quality</th>
<th>Scenario of Hong Kong Church</th>

</thead>
<tbody>
<tr>
<td>Strongly expressed</td>
<td>Weakly expressed</td>
<td>1. Churches adopting Western traditional church design methods, especially those with individual buildings. Theology and design were related but retained in a traditional manner. (see figure 2)</td>
</tr>
</tbody>
</table>

Figure 2: Church adopting Western traditional design

| Weakly expressed | Weakly expressed | 2. Most of the churches in Hong Kong lacked resources to incorporate design; together with a theological position that church was a community of believers, not a building, made design a minor issue and the concept of creating a sacred space minimal. Design was detached from theology. (see figure 3) |

Figure 3 Church incorporated with no design
3. Most of the churches incorporated with design was within this category. Churches sensitive to newcomers delivered a space with contemporary touch and warmth. Those with social services also focused more on contemporary design. They were not aware of sacred representation in the churches even relative budget was spent on design. Theology was related to design in the sense of creating a contemporary design to attract newcomers. Theology and sacred representation was detached. (see figure 4)

![Figure 4 Church incorporated with contemporary design](image)

4. Rarely seen churches with this approach but this was the most significant direction from the literature review to revitalise the essential sacred quality with contemporary manner under substantial theological standpoints. (see figure 5)

![Figure 5 Church with sacred and contemporary quality](image)
Site observation of selected churches with long term participation also revealed that church design to reflect the sacred nature was not a main concern. Through the application of some sacred symbols such as the cross and the pulpit, which were often ineffective for the holistic sacred atmosphere. It was a challenge for church design to provide both sacred and contemporary qualities. For the seekers sensitive approach, the delivering of sacred nature was not in the design brief. The sacred quality usually relied on the altar design only. The spiritual path and the careful use of symbols have been lost from traditional essence in church design. From the observations, when churches need to be multi-functional and focused on the communal side, they would neglect the sacred nature.

Hong Kong churches with limited space. Let explore different practices through the understanding of the layout from layout plans analysis from site observation.

Plan in a square shape

This was a church with a square-shaped plan with columns in the middle of the sanctuarty and entrance near altar. When location of entrance was limited by the building layout, a proper progression of space was surrendered. The biggest issue was the circulation because the entrance was near the altar, people walking passing after services started caused disturbance to worshippers.
Plan in a Rectangular Shape

Longitudinal Layout

This church was located in a kindergarten with classrooms surrounding the assembly area which is converted into a worship space. Limitation is distraction from the colourful decoration along the classrooms. The only option to set up a proper altar was the far end of a longitudinal layout.

Figure 7 Grace Methodist Church

This site was composed with three bays separated by structural walls. A longitudinal layout was created in each bay. However, the narrow width of the altar back wall was a big problem; such as when allocating the cross, projection screen, banners and pulpit, it was difficult to avoid these elements from blocking each others.

Figure 8 Shatin Free Methodist Church
Unlike the previous two churches, the floor plan of this church was possible to create an auditorium layout. This is one of the churches with a typical longitudinal layout with a central aisle and altar at the far end. It did not make use of natural lighting.

This church has created a spiritual path to prepare the worshippers’ hearts and souls before worship. There was space for people to mingle before and after service. However, the spiritual path from main entrance to sanctuary entrance was also the mingling space which made it harder for worshippers to experience the spiritual path. In term of the sanctuary, the columns limited variations in layout, thus the longitudinal layout was selected. Baptismal pool was located at the back of the altar covered by an especially designed sliding door.
In this longer length longitudinal plan, projection screens were placed in the middle of the sanctuary to create a projected image of the altar for worshippers sitting at the back. Baptismal pool was located at the back of the altar covered by sliding door.

Auditorium and Communal Layout

This church has occupied the whole floor of a commercial building and the creation of spiritual path started from the lift lobby. Altar was placed in the centre of the longer side of a rectangular plan to create an auditorium layout; with windows at the back of the altar, light was diffused into the sanctuary as a symbolic element.
This is a church with both a communal layout and an auditorium layout in the sanctuary. Although there were windows located at the back of the altar, they were covered. The space for mingling before and after service was relatively small because space for maximum capacity was one of the goals.

This is one of the few churches which both a communal and an auditorium layout had been applied, with the pulpit located in the middle of the longer side of a rectangular layout. However, this was a church without professional design, the effect was very basic and functional.
A communal layout was created through the semi-circular seating arrangement. Coffee corner and sofa area further delivered a relaxing mood within a worship space.

Summary of the Layout Concepts of Churches

Figure 15 2/F, Island Evangelical Community Church

Figure 16: Typical layout plan with a longitudinal layout
Figure 17: A variation with altar being placed at the corner to create a dynamic layout with a communal effect but the distance of the congregation with the preacher is not resolved.

Figure 18: Even though the entrance is located at the longer side of a rectangular layout, a longitudinal plan is still created.

Figure 19: Layout with altar being positioned in the longer side of a rectangular shape to reduce the distance between congregation and preacher.
The common scenario of churches was to form a longitudinal layout with altar at the far end of the worship hall (see figure 16). If maximum capacity is a key, space for mingling will be reduced. Evangelical churches focus on preaching, a layout which can reduce the distance between congregation and preacher is preferable and hence the immanent quality can be better delivered. Apart from reducing the distance between congregation and preacher, layout which facilitates the communal spirit is also significant. Semicircular layout is one of the options. However, the capacity will be reduced.

**Discussion**

**Secular social need and contemporary sacred quality of God**

The key function of a church is to house worshippers to worship the deity (Victor Fiddes, 1961; Bie’ler, Andre`, 1965; Debuyst, F., 1968; White, James 1988; D. Foy Christopherson, 2004, p.20). In modern church design, one could discover that a number of churches were designed to house as many people as possible. As described in the book, *Sacred power sacred space*, church looked like a theatre than a church; not approaching the liturgical or theological requirements (Kilde, 2008, p.155). The functional task was satisfied but the space lacked sacred quality. Actually, when churches became dual-purposes, the sacred identity faced great challenges. When more and more satellite towns or new communities were built, dual-purposes churches were the trend to solve the diversified needs in the community. 1950’s and 1960’s were the peak periods of the so-called “multi-purpose” space. In relation with massive urban development, named as “satellite towns”, the Church decided to build buildings not solely dedicated for religious activities but for variable use (Schwebel, 1994). Under secularisation, religious activities were not the prime need and they were replaced by different individualistic and social concerns.

When Torgerson (2007) discussed about nourishing the sacred especially in the immanence side, he borrowed from different scholars about their supports toward multi-purpose church based on the theology of breaking the dichotomy of the sacred and the secular. In the subsection ‘The effort to relate faith to the secular world’, Torgerson illustrated that Liberal theology intentionally or unintentionally influenced church design on the immanence of
God. Torgerson elaborated primarily on theologian Dietrich Bonheffer (1906-1945) who developed his theology from the person of Christ to searching for language relevant to secular humanity. Then, he introduced Bishop John A.T. Robinson (1919-1983) who believed that “the Christian faith had the potential to break down the artificial distinction between ‘sacred’ and ‘secular’” (Torgerson, 2007, p.17). Roberson was inspired by famous theologians, such as Dietrich Bonheffer, Paul Tillich (1886-1965) and Rudolf Bultmann (1884-1976). One of the approaches is the application of contemporary symbols. Seasoltz (2005) stated that “sacred building and sacred art are above all symbolic” (p.345). Loveland & Wheeler (2003) also described sacred church as “beautiful, symbol-filled, worship-orientated sanctuaries” (p.239). If contemporary representation wants to integrate with symbols, a transformation of new symbolic form is the key. This study opts to facilitate church design with the combination of contemporary quality and sacred identity. The term contemporary in church design indicates that there is the application of contemporary materials and technology in design such as the use of glass panel, metal, acrylic and pre-fabricated materials. An article called Contemporary Catholic architecture written by Rev. Edward J. Sutfin and Maurice Lavanoux, cited in Modern Church Architecture by Albert Christ-Janer and Mary Mix Foley (1962) mentioned that “The presentation of this heritage, however, is dated by the ‘new’ and the ‘now’ of the contemporary stage of development of the city of God” (p.1). When they described contemporary church design, they reinforced that design must be created and addressed for the people of our time. Hence, the use of current materials to fit the time and spirit of people we live in was vital (Pichard, 1960; Hammond, 1960; Bruggink & Droppers, 1965). In the article, Contemporary Protestant Architecture by Dr. Paul Tillich (1987), Professor in Harvard Divinity School, he stated the dilemma of applying tradition in practice: “The polarity of tradition and contemporaneity in all religions… Both Protestant liturgy and Protestant theology retain many elements of the common Christian tradition: Why not church architecture?”. To answer this question, he reminded people that symbols used traditionally but change in style continually. It means that contemporary vocabulary can be related to tradition with a transformation of traditional symbols, spiritual path and more elements to contemporary style. In the book, Sixty post-war churches (1956), an inspiring statement was written with similar answer: “The ‘Truths’ are not contemporary, but that only the means of expressing them are” (p.7).

Conclusion

Analytical Framework: Functions of Church in Relationship with the Three Attributes
When a church is established in terms of design, the practical function and the sacred function are the two categories under consideration. These issues are depended on the theology to influence the decision making. Hence, theology is the key (see table 3). These three concepts: theology, practical function and sacred function are related to the three attributes of church. When discussing theological definition of church, church is identified as the community of believers. When considering church as a place of worship, the primal concern is the practical function of a worship space, such as the capacity, the layout, and the sound effect. When one associates church as the house of God, the concept of symbolic function is brought forward. Community is the spiritual level which is the ultimate definition theologically. Undeniably, this is a worshipping community united together in a place dedicated for God, and which is named the church or the house of God.

While this thesis explores the dilemma between contemporary expression and sacred expression, it is known that contemporary design focuses more on the practical function
and the performance as a worship space whereas the sacred design reinforces the symbolic function and the representation of the sacredness of church as the house of God. In order to link the central issue, a theological standpoint must be applied to represent the physical existence of a church community by balancing the contemporary and sacred representations. The sacred expression is associated with symbolic function which is one of the traditional essences of church design.

When church associates with community services, it is revealed that the design is pinpointed on the functional need of the social services. For churches affiliated with social services, it was discovered that the designs were mainly contemporary and social services oriented. A balance must be achieved through a theological reflection so that community of believers can benefit from both functions. Simultaneously, the sense of belonging could be achieved.

### Table 3 Functions of Church in Relationship with the Three Attributes

<tr>
<td>- Sacred representation (traditional essence associated with sacred expression requires transformation)</td>
<td>Community</td>
</tr>
</tbody>
</table>

The wonder effect as mentioned by one professor is vital for church space. No matter what elements are applied to deliver the sacred, the magical experience through spatial design is
reinforced. It is undeniable that wonder effect in church space must be associated with sacred quality. In one-flat church, the representation of the immanent nature is more appropriate spatially.

**Design Guidelines: Spiritual Path as one of the guidelines in Creating Sacred Space**

The research findings indicated that design was a growing concern; however, church design was targeting on the contemporary issues such as the need of the social community and the application of contemporary aesthetic. It is concluded that this phenomenon was a serious issue in Hong Kong churches which needed to be amended. When it is revealed that this issue was quite complicated with the lack of existing practices to support the urge for both sacred and contemporary qualities, the researcher wished to generate design guidelines to contribute more reflections and practical suggestions for pastors and church administrators. One of the selected elements for church builders to think deeper is the creation of a spiritual path. Although churches under the constraint of limited space, spiritual path can have significant contribution in creating a sacred space. It works with creating an immanence space, without the necessity of high ceiling, through spiritual path to experience the sacredness. The traditional approach is the creation of a linear path (see figure 24). To modify from linear path, sometimes split path is created (see figure 25).

Below is a proposal of different spiritual paths which can be implemented in one flat churches. If there is a lift lobby, the spiritual path can start from it - from lift lobby to reception, leading to worship hall and then the location of altar. It then depends on the layout to decide whether the designer can create a U turn or L turn to extend the path (see figure 21-25).

Author Biography

Dr Louis Poon Shek Wing
Dr Louis Poon is currently senior lecturer of Department of Design at Caritas Bianchi College of Careers. He has obtained his Bachelor of Arts in Design (Interior Design) from the School of Design, The Hong Kong Polytechnic University in 1989. After graduation, he worked as an interior designer with specialty in commercial projects. He was appointed as team leader in 1991 and was responsible for a number of international and renowned clients. From 1993 onwards, he shifted to study theology and he has obtained his Master of Divinity from China Graduate School of Theology, Hong Kong in 1996. He kept on his professional practice in interior design projects such as church, kindergarten and elderly centre. In 2003, he decided to integrate his extensive and diversified experiences in interior design and culture (especially church) into a PhD research project. He started his research as a full time PhD student in 2004 in the School of Design, The Hong Kong Polytechnic University. During his study, he was employed as Visiting Lecturer to teach subjects on design, culture and theory, design history, design research and design studio projects. His research expertises are sacred space design in urban environment, social design and community design.
Sensory Reflection towards Product Design Ideation

Abstract

As humans’ information processing abilities, have become more and more disconnected from their senses due to an increasing quantity of abstract information, so have design processes. There is a demand for designers to include human sensation as part of engaging product forms and experiences. This qualitative case study explores the role of senses and their potential use in design ideation. A literature review of related theoretical and pragmatic perspectives and a survey of 15-20 product examples that provide unique sensory experiences are analyzed and sorted through four sensory design strategies: Sensory Augmentation, Conversion, Transition and Isolation. Using the four strategies as core concepts, a Sensory Reflective Framework with a mindful focus on sensory appreciation and translation is proposed to support designers’ ideation in creating unique product forms and experiences. The paper reports the process and findings of a sensory ideation workshop which was conducted based on the framework, and further discusses the development and implications of the framework in supporting designers’ sensory ideation.

Keywords: Sensory reflection, Sensory design, design framework, ideation, reflective practice, industrial design

Human senses are natural ways to gather information from our surroundings. The way we see, smell, hear, taste and touch, molds our perception of an object or the outside world. However, growing technologies and urbanization have led people to become disconnected from their sensory capacities. Further, human senses are increasingly neglected in information-gathering and decision-making processes when people yield the role of their senses to cognitive, reasoning capabilities. Humans are often oblivious to sensory stimuli and related information in their surroundings unless deliberately made aware of it. This qualitative design case study proposes a framework for using the five human senses (sight, smell, sound, touch and taste) within an industrial design ideation process for building emotionally engaging product forms and experiences.

Sensory modalities can still serve as a primary touch point through which people receive information about their environment and products with which they interact. 70% of UK and US Millennials crave experiences that stimulate their senses (JWT Report, 2013); these sensorial experiences can be augmented by considering new concept creation of products and brands, as an integral part of innovation (Currano et al., 2011). Although it has been well-
acknowledged that senses play a role in effective product design, research has found that perceptual processes for all people are not identical (Haverkamp, 2011). Thus, there is value in research that can systematically employ the characteristics of sight, smell, sound, taste and touch as a part of a design process.

Grounded in related bodies of research on human sensory abilities from psychological and design perspectives, this study aims to understand the practical and emotional significance of sensory experience in human-product interaction. The assumption that undergirds this research is that designers’ deliberate focus on sensory inputs could be developed through their reflections on related experiences and associated meanings toward the development of novel product concepts.

**Research Methodology**

The concept, *sensation*, as defined in this research, refers to the processes of sending and receiving information through human sense organs. The Greek philosopher, Protagoras, as early as in 450 B.C, described man as a bundle of sensations, underlining the assorted senses and their manifestations in human perception (Watson, 1907). Without the diverse effects of the senses of seeing, hearing, smell, taste and touch, our lives would be uninspiring.

In his book, *Sensual Relations* (2010), David Howes observes that sensory history dates to the 16th century, a time when people were more attentive to smells and sounds (Febvre, 1982) and visual cues were more significantly considered. A glimpse of our imaginative past can help us to project future trends by understanding the preferences of the earlier era. Historical precedents for the value of sensory data in human survival as well as quality of life provide a context for this focal research topic, Sensory Reflective Frameworks.

The current case study is a qualitative method of inquiry reflecting two key features of qualitative research, such as understanding the various perspectives on sensory perceptions in real-world settings (understanding the context based on the environment around us) and constructing hypotheses or concepts from the available data.

**Qualitative case study approach for Sensory Design**

Senses play a crucial role in a human-product experience because of our “intimate familiarity” with them (Fenech & Borg, 2006). This qualitative case study is undertaken to learn the underpinnings of sensory studies by backcasting¹ (Robinson, 1990), seeking an understanding of the relationship of senses and emotions and how they are manifested in design. This study investigates various literature data sources and conducts a survey of products that exhibit sensory properties readily (characteristics exhibited by each of the senses like color, texture, temperature etc.). Together, these approaches led to an awareness of how the senses prevail in design and in other fields; the combined approaches also revealed the methods by which these senses are employed. This study of the literature concludes that sensory qualities could be considered intentionally and productively by employing the sensory strengths within industrial design ideation.

---

¹ Backcasting was a method used in Planning outlined by John. B. Robinson. This form of scenario planning was used to explore possible futures by construing the past 20 – 100 years. (Robinson, 1990).
Significance of Research

This research topic is unique in not only proposing a framework which is original to this study, but also in probing how the framework could support designers consider rich and unique sensorial experiences in a product ideation process. Providing a context for the framework described in this thesis, there are other design theories that reference the role of the human senses in the design process. Chang (2006) offers perspective on using gestalt theory to help create innovative ways to design and use multisensory displays; Haverkamp (2011) stresses the importance of connections between multiple sensory faculties for product design; Lee (2013) evaluates the multisensory product-user experience in different scenarios; Schifferstein (2006, 2008), bases his work on awareness and contribution of messages obtained from different sensory channels; and Zuo (2001), examines the psychological responses by humans to material texture and sensitivity, lending theoretical support for this research.

Literature Review

Sensory Integration in Psychology

As designers, we are gestalt\(^2\) thinkers; we are constantly organizing the fragments of sensory inputs perceived from the external environment into patterns based on nine principles similarity, continuation, focal point, figure-ground, belongingness, balance, proximity, common fate, closure (Chang & Nesbitt, 2006). This helps our brain process the bits of information into a whole, to understand and navigate through our everyday processes.

We are constantly processing information obtained from our senses through our nerve impulses to the brain. The brain filters out information into what is necessary and what is not. It is interesting to compare the relation between what is received and what is processed consciously in terms of their amount. The table below shows this relation with respect to the five senses (Figure 1).

---

\(^2\) Gestalt Psychology suggests that we make strong and meaningful connections from the information we perceive in the chaotic world (Feinberg, 2013). The original idea was introduced in 1890 by Christian von Ehrenfels.
We can see that vision is the most used sense, but only 1 out of every 250,000 bits of data received by a human eye is considered useful. The same ratio applies to the other senses. As a designer, it is very important to comprehend this information and maintain a balance of signals going into the senses to avoid sensory overload.

Sensory data is the most fundamental aspect of information processing in human perception and experience. Human beings evaluate their everyday experiences through one or multiple sense organs and we are familiar with how the perception of colors is different
from the depth of an object. The pyramid of learning by Williams and Shellenberger (1996) (Figure 2) explains how sensory systems work as the foundation for integrating information intake and processing in our body before being further translated into perception and cognition. This bottom-up process demonstrates how the information received from our senses develops into other forms of perceptual, behavioral, cognitive systems. This pyramid identifies the apex to be emotional or intellectual process, which requires the understanding of sensory behavior that can in turn be leveraged into creating emotionally driven artifacts.

Senses and Emotions

Emotions are complex bodily sensations felt as we encounter pleasant, unpleasant or neutral changes that occur after the information from our sense organs within our body are processed. We make meaning of the existing environment through an input (perception) and output (action) oriented system. Sensory data can either validate or disrupt thinking patterns. Research shows that design evokes emotions in the user through habitual use (Eyal & Hoover 2014). People love or hate a product based on how it evaluates over the categories of visceral (how things look, feel etc.), behavioral (effectiveness and usability), reflective (meaning of things) (Norman, 2004) (Figure 3).

Take for example, a stainless beverage cup which is aesthetically pleasing to the eyes, but the condensation on the surface while serving a cold drink or the surface heat on pouring a hot beverage makes it unpleasant to use. It is at these times that we need to consider the visceral aspects (Sight, smell, sound, taste and touch) of a design for the promise of its future usage, which are channelized into valuable experiences and meanings.

(Figure 3. explains how sensory inputs are used to feel, understand ease of use and make meaning in a design (Norman, 2004))
The concept of emotion-driven design is relatively new in the industry. Wondersphere is one such experiential, multisensory initiative proposed by Bressler Group: the sealed mobile chamber (Figure 4) provides a playful and healing environment with added emotional benefits for hospitalized patients and immune-compromised children so that they can interact with nature by digging in the soil and playing with nature without any risk of infection. We can neutralize one or more of our senses temporarily to heighten the others for intended effects. Clearly, psychologists, anthropologists and other professionals have studied the importance of understanding the manifestation of sensory characteristics in their fields to make meaning of this _arational_ process of human sensations. How human senses gather and process information has been explored, but ideating for an unconscious behavior (Kamil & Abidin, 2014) like these sensations is an _arational_ process that is rationalized in this design case study. One of the concepts explored through this inquiry is how the meaning-making process of research can be achieved through reflection on a portion of the familiar data or the whole body of data collected. This paper goes on to propose the concept of ‘Sensory Reflection’, in the next section, an original thought process that developed through this study.

**Reflective Practice Using Our Senses**

According to Schön (1983), reflective practice is a form of thinking and a process of continuous learning which involves paying attention to the important details of everyday activities and carefully reflecting on these patterns. Schön describes three types of reflective practice:

- **Reflection-in-action:** This is a phenomenon which helps in developing a deeper understanding of the problem through thinking while acting.
- **Reflection-on-action:** This is a reflection of our thoughts after the practice is done.
- **Reflection-on-practice:** This is a combination of both first and second types of reflective practice.

---

3 Arational by definition is philosophical idea that is not within the domain of what can be analyzed by reason. (WikiDiff, 2017)
This design case study finds that the knowledge gained through reflective practice based on sensory information is significant for helping a designer to critically examine their own design process. The result of the sensory reflective practice is a more personal and creative solution to design problems. The Pilot Design Workshop, described later in this paper, further elaborates how this method of self-reflection in ideation was tested. The current study proposes a novel form of creative self-reflection in design by adding a sensory component to the design problem to generate a wide range of solutions.

**Sensory Reflection as a Form of Design Ideation**

The developments in technology require designers to continuously better their design processes and methods in correspondence with a new design environment; thus, a designer’s reflection on current practice is a crucial part of the improvement. Reflection as a designer means to step back and break down one’s own process by defamiliarizing a familiar design subject and context, reframing related problems, and speculating about different perspectives on it (Reymen, 2001; Schön, 1983).

As suggested in this study, the integration of sensory data in designing novel products and experiences could be approached from the view of ‘reflection in action’ (Schön, 1983). This would be accomplished by a designer in bringing conscious sensory awareness to a design process and reframing diverse sensory modalities and related human behaviors to product forms and interactions. In this vein, a ‘Sensory Reflective Framework’ is proposed for supporting designers’ reflection on human sensory faculties and their related meanings in product design ideation. In what follows, four strategies to deliberate the practice of ‘Sensory Reflection’ to product design ideation are described as the core concepts of the proposed framework.

Grounded in the previous research, Sensory Reflection can be delineated as a reflective design approach with which a designer can intentionally create a new sensory experience based on how human sensory faculties receive and treat information. In this design case study, a designer’s self-reflection is pursued in order to consider many non-physical aspects (Razzaghi, 2005) of designing that may be influential to the design process, and ultimately, significant to users’ needs. To this end, a questionnaire was created to explore, reflect upon, and redesign the Sensory Reflective Framework. The next section explores different sensory design guides that offer insight on the value-opportunity gaps to further this research work.

**Various Sensory Design Guides and Product Examples**

There are very few design guides that elucidate the role of human senses in product design process. There have been studies that present theoretical perspectives related to human sense, but most of them center on evaluating sensory qualities of existing products, rarely informing a generative process to ideate novel product concepts in terms of how to consider and use human senses.
Five Senses Graph

Senses have been employed as a form of evaluation for human-product interaction: for example, the ‘five senses graph’ by the Industrial designer Jinsop Lee (2013) shows Lee’s sensory experiences with his everyday product interactions. Evaluating sensory experiences on a scale of 1-10 (1 being the lowest involvement of his senses), Lee collected data for 3 years using a journal. The wider area under the graph indicates higher sensorial qualities of a product (Figure 5). Lee’s graph was meant to evaluate and compare sensorial experiences with current products rather than informing new product design in terms of how to consider and manipulate design elements relevant to human senses.

(Figure 5. shows five senses graph by Jinsop Lee shows a motorbike was evaluated on scale of 1-10; smell and taste was the least accounted for senses in transportation design (Lee, 2013))

Tools Facilitating Multisensory Design

Schifferstein and Desmet propose ‘Tools facilitating Multisensory Design’ (2008) to support designers’ new product ideation with novel ways of providing sensory stimulation and feedback through designs. They develop a matrix with four tools that a designer needs to consider — Sensory Sensitizing, Sensory Sampling, Sensory Communication, Sensory Building blocks. They raise designers’ attention to the significance of multisensory design. However, they do not specify how to handle multiple sensory perceptions and sensory systems in design ideation to create intended product experiences.

Synesthetic Design

Michael Haverkamp in his book, Synesthetic Design (2011) details the theoretical aspects of sensory perception and distinguishes ten different sensory modalities- Visual (seeing), Auditory (hearing), Olfactory (smelling), Gustatory (tasting), Vestibular (sense of balance and body movement), Tactile (touching), Thermoreceptive (feeling temperature), Proprioceptive (positioning and movement of the extremities), Interoceptive (body condition and organ
activity) and Nociceptive (feeling pain). He explains how gestalt principles like similarity, consistency, proximity and seeking an order in chaos affect perception of objects and establishes connections between senses at their iconic (imagining sound based on the illustration of the words in comic writing) and symbolic (associating colors to smells) levels. However, these methodologies do not say how to use these sensory aspects as a primary factor that drive design ideation.

Sample Product Survey

In this study, a survey of 15 – 20 products, which are deliberately selected in consideration of their unique sensory stimulation in use (See Table 1.1 A, B, C), was conducted to analyze and reflect on various sensory characteristics exhibited by current products in practice. The survey revealed several keywords of sensory characteristics, including emotional longevity, personal connection, sensory enhancement, sensory isolation, concentration, experience design, technology, noninvasive design, sensory cross wiring, synesthesia, sensory stimuli, experience design, simplicity, sensory stimulation, immersion, exploration. These keywords were further categorized along with theoretical interpretations of prior research of the sensory design guides and a few other methodologies (See Table 1.2 A, B) to form the foundation of this Sensory Reflective Framework.

The preliminary prototype of this design framework was tested as a part of pilot design workshop to understand how designers would interpret and employ it for product design ideation. The Sensory Reflective Framework (Figure 6) consists of four Sensory Design Strategies and a Sensory Library (Figure 11), which lists different characteristics of the five senses to consider in generating creative product concepts beyond visual sensory features in consideration.

Framework Development

The framework consists of the four strategies—Sensory Augmentation, Sensory Conversion, Sensory Transition and Sensory Isolation—based on how multiple sensory modes are related to each other (y-axis) and change over time (x-axis), both of which are significant elements of sensory experience with a product (Figure 6). This form of reflective thinking for ideation intends to encompass simple yet comprehensive strategies that allow a designer to perform basic actions of addition, subtraction, multiplication to generate a range of creative solutions.
Sensory Reflective Framework

The qualitative analysis of the sensory characteristics of selected products identifies several categories of sensory design approaches that could constitute the framework. The initial framework has been revised through multiple iterations based on the feedback from pilot design (See Table 1.3 A and B). The proposed framework is the synthesis of the reflections from the preliminary literature review about related theoretical perspectives and the survey of product examples. In what follows, the four design strategies of the framework are described with supporting research and product examples.

**Sensory Augmentation** is a creative thought process which helps a designer to create a sensory experience that extends one sensory mode to multiple sensory characteristics beyond visual sensory cues (e.g., color, contrast, motion). It helps the designer to explore novel configurations or combinations of different sensory modalities, often to reassure a product function or user action with multiple sensory confirmations (Haverkamp, 2011).

Supporting Research: Augmentation means to increase or supplement the existing. We use vision as our primary sense to understand and confirm the perception from other senses, but more novel experiences are created by leveraging the use of other senses. David Eagleman (2015), a Neuroscientist, provokes sensory addition or augmentation by applying digital signal processing and audio codec technologies to expand our perceptual experience with biological sensory organs. His experiments were mostly conducted to enhance hearing with the aid of audio signal processing technologies, but further aims at restoring newer perceptions by using atypical sensory modalities like technology along with our sensory streams.

(Figure 6. illustrates the proposed Sensory Reflective Framework conceptualized for Design Ideation)
Each person can detect different characteristics of sensory modality working in congruence with the others. We live in a world full of information and innovative technology in realm of virtual reality and augmented reality. It is an emerging (imperative) design challenge to manage the multidimensional data generated in such hybrid realities beyond the two-dimensional screens (Papagiannis, 2015). The physical world involves natural interactions with objects using different senses, which could inform the conception for a virtual space. Skeuomorphism is a design trend conceived to design objects in a software or digital space to mimic its real-world counterparts (Campbell-Dollaghan, 2014). It was principally used in iconography. This concept can be useful in designing a virtual space as close to the physical realm as possible. Besides VR and AR, the addition of senses can have functional benefits in specific domains of practice, for example, by using tactile models of various anatomical parts to assist doctors during surgical reconstruction (Papagiannis, 2015).

(Figure 7. shows Synchrony is a music platform that helps parents and children with autism reduce tactile defensiveness (Tay, 2015))

Example: Synchrony (Figure 7), a conceptual music platform to promote music therapy and intimacy between parents and children with autism. This augments a hand drum with a soft silicone surface, which responds to user’s touch and provides feedback with changes in volume and resonance. This is an instance of how materials, vibration and level of sound are integrated to augment tactile sensation, thus to enhance the kid’s sensory stimulation.

**Sensory Conversion** is a strategy for altering the behavior of one sensory characteristic with respect to another by combining them to create an interesting design dimension. In this framework, Sensory Conversion is not a mere replacement of one sensory modality with another because of a deficiency or inefficiency. Instead, it is grounded in a careful understanding of how one sensory aspect can be related to as well as influenced by the other sensory aspects in design ideation. Designers can draw a premise about how actions related to sound would affect one’s visual perception; smell to taste; touch to taste; or as illustrated in the example, the sense of touch like peeling or scratching could change the visual aspect of a product (Figure 8).

**Supporting Research:** Each sense organ converts external stimuli into signals with efficiency and versatility (Henshaw, 2012) and our brain is trained for parallel processing of
sensory stimuli and responding to them. This happens both consciously and unconsciously. Often one sensory modality out-performs the other or lose their ability to perform well. In both the cases, substituting one sensory modality over another or altering the behavior of one sensory characteristic with respect to another adds an interesting design dimension to create a collective outcome.

The idea of sensory conversion is primarily based on ‘Sensory Substitution’ introduced in the 1960’s by Paul Bach-y-Rita, a pioneer in cognitive neuroscience to study effects of tactile characteristic with respect to other sense. His book, ‘Brain Mechanisms in Sensory Substitution’, introduces a way to use characteristics of single sensory modality to change the stimuli of another sensory modality. This led to the foundation of many upcoming studies, like V.E.S.T (“versatile extra-sensory transducer”) which feeds brain information to alternative sensory channels for instance one could hear the world through vibrations felt through the vest on their chest (Eagleman, 2015).

(Figure 8 shows the creative packaging of the beer bottle from beck’s brewery (Lin, 2015))

Example: Beck’s brewery from North Germany is an example of creative and playful packaging: a user can scratch on the aluminum label of a bottle as a creative canvas open for personalization. This is an instance where a visual sensory character changes in relation to touch.

Sensory Transition is to transform sensory characteristics over time by exploring how a product would unfold new forms and sensory qualities in a temporal dimension. The longer a user spends time using a product, the more the user would develop emotional engagement with the product; and designers could consider this temporal change as an influential factor on user’s attachment to a product.

Supporting Research: Everything we experience is analyzed, filtered, sorted and allocated a space in our brain. Brain combines and processes multiple sensory inputs received through sight, olfaction, auditory, gustation and tactile into functional units over a period. Information from different sensory is handled and processed at different speeds by different neural networks (Eagleman, 2009).

Sensory inputs are utilized consciously or unconsciously to influence perception, decisions and
behavior over habitual use. (Stein, Stanford & Rowland, 2009) (Eyal & Hoover, 2014). Based on the understanding of how each sensory characteristic change with the progression of time, designers could explore novel sensory experiences to deepen user’s emotional engagement with and attachment to a product.

(Figure 9. shows the Fred Wake up cup which changes the sleepy eyes to bulging to indicate the user’s reaction to a morning cup of coffee (Orchant, 2013))

Example: A hot water coffee mug changing the color of the material or graphics on the outside as time progresses to indicate the temperature of the water inside (Figure 9).

**Sensory Isolation:** Isolation is usually viewed as a negative connotation of things. In this study, it implies intentional cutting off other sensory stimuli or temporary detachment from them to reinforce one focused sensory modality. Why do we require this for design ideation, one might wonder? A designer can take a step back and reflect on this list of possible choices and determine which sensory aspect to enhance or diminish in ideating new product concepts. Considering the sensory cues in isolation might not improve the product in terms of technology but will enhance the sensory experience.

Supporting Research: We observe a series of events from our environment and tend to overload our senses. That is how our brain functions by building connections and associations between various words, colors, sounds, in general to develop perceptual patterns. It would be an endless process to sort and analyze these prevailing patterns to meaningful and meaningless information; and sometimes isolating and/or eliminating sensory inputs may help screen through and focus on critical information.

(Figure 10. shows the Eidos mask which isolates the sound in the user’s environment (Etherington, 2015))
Example: Eidos Vision and Eidos Audio (Figure 10), a conceptual headset proposed by the Innovation Design Engineering students of Royal College of Art, is a good model of sensory isolation. The mask intentionally isolates facial movement and enhances the way how its user sees. The mask also fits the user’s ears and mouth to neutralize the background noise and hear what the user speaks clearly.

**Sensory Library**

*Sensory Library* (Figure 11), as another component of the proposed framework, aims to provide designers with options of specific sensory properties from which to draw inspirations about how each sensory modality manifests itself in design. This library can be used in combination with the aforementioned *Sensory Reflective Framework* (Figure 6) as guidance for ideating new functionalities and sensory experiences of products.

Each category in this library is based on the inferences from different research journals. It contains the features of each sensory modality and how they are specified in other sub-categories. Understanding these sensory stimuli provides designers a new perspective to deconstruct familiar sensory experiences and explore new ones beyond color, form, and material. In particular, there is an interesting research finding regarding the olfactory sense: odors can be classified into 10 profiles and various odors can be manufactured by combining one or more of the 10 basic odor profiles (Castro, Ramanathan & Chennubhotla, 2013).

(Figure 11. shows characteristic properties each sense manifests itself in a form of Sensory Library to inspire designers in ideation.)
The sensory design properties that each human sense organ can perceive can be classified as listed below:

- **Sight**: color, form, material, motion, dimension, text
- **Smell**: fragrant, sweet, chemical, minty, pungent, fruity, woody, resinous, citrus, nutty, decayed
- **Sound**: volume, pitch, depth, tone, noise
- **Taste**: temperature, flavors, texture
- **Touch**: temperature, pressure, texture, motion, haptics

These sensory design properties could be combined to exhibit various sensory manifestations and corresponding user experiences; for example, Visual sense has ‘dimension’ listed as one of the sensory design properties and is further categorized into two-dimensional, three-dimensional, depth, solid-void relationship etc., The following section describes the ideation workshop conducted to collect preliminary feedback on the proposed framework, followed by discussions about findings and further implications.

**Pilot Design Workshop**

A pilot design workshop was conducted to evaluate and improve the Sensory Reflective Framework with four participants spanning for thirty minutes per person. The workshop revealed strengths and weaknesses of the proposed framework, although the testing was limited in terms of the number of subjects and the scope of design activity.

(Figure 12. is the workshop questionnaire with left hand side designed to understand participant’s methodology and right side provided to ideate using senses.)
Task

Participants were asked to apply the proposed Sensory Reflective Framework as a part of a questionnaire (Figure 12) and the Sensory Library (Figure 13) presented in two separate sheets to ideate a new product concept. The questionnaire was introduced to obtain better insight on the framework. For the ease of understanding, the products selected for the workshop were the ones that were likely to be used by most people. The four products were – coffee mug, pencil, stainless steel spoon and a water bottle.

For each product, the respondents were asked four different questions: 1) What factors make this product personal to you? 2) As a designer and user, what would you like to change about the product? 3) How does your design process look? 4) Do you consciously consider senses in your design ideation process?

The second part of the questionnaire asked the respondents to navigate through the proposed framework and ideate freely. Each individual ideation session lasted about 20 minutes. It was followed by a short debrief about how the participants understood the questionnaire.
Analysis

(Figure 20 is the illustration of a few resultant concepts from the design workshop.)

Responses by each participant was transcribed in detail (See Table 1.5 A, B, C). This gave an insight into an individual’s design process, design preferences, emotional responses and innovative product ideas generated through the framework.

Compelling findings were collected/observed from the workshop (Figure 14). Participants visualized a re-designed spoon in multiple ways, including adding a heating element to the spoon, so that the color changes with temperature to tell whether food is likewise hot to eat. It would be an interesting experiment if the flavors would change with the usage of spoon overtime. This could help design an engaging culinary experience when complemented by a sound note. Food could be a musical symphony. On the contrary, the spoon can be designed to make food gradually taste worse, which could be a dietary aid. This framework has potential to generate new product ideas in consideration of repeated and habitual use. The detailed transcript of the workshop can be found in tables. (See Table 1.5 A, B, C)

Results

Phase one of the workshop was executed successfully with all the four participants’ understanding and executing the given task of answering the questionnaire. Observing each respondent during the task, it was evident that each strategy within the framework without a detailed explanation slowed their ideation process. It was also noted that the participant used the sensory library for inspirations of sensory design characteristics over habitual use.

In phase two of the workshop, the participants reflected on the whole ideation process and cited that it was an interesting test of using senses to think and conceptualize creatively. Two of the participants agreed to having considered only tactile and visual aspects while designing and artifact. One of them wanted to know how this framework could be used in their own design process.

*Sensory Isolation* proved to be the easiest technique in the framework with all four
participants using it as intended. On the other hand, most participants had difficulty in understanding and applying the strategy of Sensory Conversion to their ideation. This may be because it requires the participants to predetermine what changes they want to envision in their product, although they are not yet familiar with possible sensory properties. Only two of the participants could accomplish this task.

The participants mostly seemed to clearly understand what they were asked to do, but the ideation only with images and guided questionnaire limited their design space. Interactions with actual artifacts could have further inspired them with richer sensory stimuli. Regardless of the limitation, the workshop provided deeper insights into the individual participant’s design process as well as their interpretation and use of the provided framework in new product concept ideation. The findings are used to revise the visual representation of the proposed framework and library.

Revisions to the Framework

Conforming to the results from the workshop, the framework was redesigned by categorizing the four strategies based on the number of sensory modalities it involved and how they changed with time. The four strategies were renamed and provided with a description and a suitable example to supply the users with a clearer understanding of the navigation of the framework. (See Table 1.3 A, B)

Sensory library (figure 11) was visualized using icons instead of images so that the users could consider the categories the sensory design characteristics represent in general and not abstracted by the imagery that is presented in front of them.

Conclusion

This research examined the role of human senses in design through an investigation of relevant theoretical perspectives with an objective to support designers’ conscious sensory reflection in their design processes toward novel and rich sensory experiences with products. This study sought to ascertain how a qualitative research method of gathering and reflecting on sensory data could yield a method of product design ideation that uses inputs and outputs from the five human senses. When designers make a conscious attempt to understand the sensory attributes that influence product design and corresponding user interactions, they can generate novel ideas by leveraging sensory modalities and their manifestations through designed products. This sensory-attentive strategy could potentially help designers achieve emotionally-engaging designs with enhanced sensory characteristics.

While our senses are generally used for evaluation and verification of actions during product use, the proposed framework developed in this research is unique in that it seeks to deliberately push designers to consider sensory aspects of product experience in the design ideation phases. This study, as an initial attempt to actualize the goal of conceptualizing a sensory reflective practice, has defined four sensory design strategies and showed how they could be used to envision new and creative product ideas. Further studies are needed to contextualize the proposed framework for design ideation in practice.
Future Exploration

The ideation framework proposed in this thesis aims to complement current design processes by emphasizing sensory reflections in product experiences and eventually developing corresponding contextual user scenarios. Future work is needed to investigate and observe the use of each strategy in the proposed framework and probe its relevance to habitual uses of products over time.

Further, additional studies could be conducted to identify the sensory profiles exhibited by discrete user groups, including sensory tendencies that occur across various demographics or cultures. Finally, the continuation of the design ideation workshops described in this research could contribute to the identification of other sensory design strategies apart from the four proposed in this study.

Table 1.4 Selected ideas from the Pilot Design workshop

Table 1.5 A Data Collection from the Workshop
01

**Product:** Spoon

**Preference:** As the user, I would like a thicker handle that is maybe a softer material

**Design Process:** Finding benchmarks- what’s missing or what’s nice from those benchmarks- contrast it with current product- then I would try to incorporate those identified elements into a new design- reevaluate- make a mock-up – testing it on few people- render- 3D print a prototype – reevaluate before final

**What makes it personal to you?** If the product is adaptable to my body in some way or if I am able to choose some aspect of its aesthetics. Also, after a long time use, I will probably start to associate emotions with the product.

**Sensory factors in your design:** Touch / materials are the main thing I think about when designing

Sensory Isolation: Adding a heating element to the spoon would be neat. Ensure each bite is hot when you eat. Changing the texture on the handle might be nice for better grip.

Sensory Transformation: It would be cool if color changes with temperature so you would know when your soup was too hot to eat that you wouldn’t burn your mouth

Sensory exploration: It would be interesting if more the spoon is used the flavors would change, making a culinary adventure or on the flipside, if it made food gradually taste worse as like as a diet aid.

Sensory integration: This could get really crazy since spoons kind of already utilize many senses with food. An added layer of noise might be interesting to enhance the overall experience if different foods made different noises making a food symphony. Wouldn’t that be crazy. Food pairing according to sound than taste.

**Suggestions:** I was little unclear on what to when it came to the matrix as it made me think about SIT techniques at visualizing the solution before coming up with the problem which is pretty cool. That might be resolved with a short explanation at the top of the matrix though.

**Further probing:** Before I was thinking only about tactility, I thought temperature was really something that I would not have thought about. It would be helpful for people to list out that are currently there and to see what is missing or to be considered. But no, in general I think you have covered everything. A little bit of explanation of stuff would be good.

02

**Product:** Pencil

**Preference:** change its shape from being hexagonal to cylindrical

**Design Process:** Familiarize with design brief/problem/ client- ideate/sketch/ word play- rough draft of design with media/ mock up- client feedback- refine or go in another direction

**What makes it personal to you?** Soft colors, solids, not usually attracted to patterns, smooth form or texture

**Sensory factors in your design:** No, they are generally unconsiously considered.

Sensory Isolation: Minimizing the angular geometric body shape to fit more comfortably in your hand
Table 1.5 B Data Collection from the Workshop

Sensory Transformation: Woody earthy **fragrance increases** when sharpened
Sensory exploration: The smooth **glossy texture fades with time** and good for use
Sensory Integration: The shiny **material** is smooth to touch, woody and earthy **fragrance** and added **sound** when pressed against fine grain paper

**Suggestions:** This exercise was very much conscious because of the **sensorial factors being primed.**

**Further probing:** mostly straightforward. I was just confused **which product I was using.** I would have eventually figured it out. Flow of the questions worked well. First thing I think of is color, all I think of are **obviously visual.** You can create volume by weight of a type. **Doesn’t have any physical weight but visually looks heavier.**

**03**

**Product:** Mug

**Preference:** Based on different scenario and users, I will change the shape, size, color or the handle after research

**Design Process:** Research- define problem- User scenario- product definition- ideation- refinement-test

**What makes it personal to you?** **Ease of usage** will be essential consideration

**Sensory factors in your design:** This is not the top most thing that comes to my head. It is last one to be considered but **needs to be reminded**

Sensory Isolation: Add **more texture, color**

Sensory Transformation: **Color and texture** can let user feel **flavor**

Sensory exploration: the **changing temperature will affect the texture and color.** Changing more layers of texture can keep drink warm.

Sensory Integration: adding **texture, temperature, smell, color**

**Suggestions:** I think the guideline gives me an overview of **how to design and create sensory product.** It’s really cool. But I don’t know **what’s the relationship between them** and what is the result in the end and what kind of product should use this guideline.

**Further probing:** I do not know the sequence. What next?

**04**

**Product:** Bottle

**Preference:** I prefer simple and minimalistic.

**Design Process:** choose an audience- making scenario- task analysis to find pain points- proposal to get feedback- refine- test- repeat

**What makes it personal to you?** **Color, text, texture, graphics**
Table 1.5 C Data Collection from the Workshop

**Sensory factors in your design:** Yes, sensory aspects provide first impression to people. It provides **credibility**. No one likes to buy bad things or bad products

Sensory Isolation: Reduce the graphics/ change the color/ change the material to anti-heat plastic

Sensory Transformation: one- click open/ separate section for water or tea bag

Sensory exploration: heat changes, form/ color changes

Sensory Integration: texture/ visual change to sense temperature of the bottle

**Suggestions:** Sensory exploration and integration are cool ideas. What if we are designing a new product? What to do if we are redesigning? Explain the process?

**Further probing:** Give clearer examples.

**Analysis:**

- Clarify the labelling
- A bit of explanation of what each category is
- Clearer test layout
- How to change a property visually without affecting the actual volume?
- How to consider ease of use, aesthetics and adaptability?
- Emotions gets enhanced over time
- Cohesive library
- Explain with clearer examples
- Relationship between each property

Author Biography

Pratiksha Prabhakar
Is a graduate student designer from College of Design, Architecture, Art, and Planning, Cincinnati. The author is a fusion of Researcher, Designer and an Architect, who indulges in creative problem solving through design. She is a reflective practitioner who believes in process and iteration as much as the outcome. Through her academics and professional practice as an architect and designer, she has a keen interest in human behavior, psychology, perception, and its value in a design process. She has industrial and cultural understanding of India and Unites States which has helped her with many successful collaborations.
Qualities of Public Health. Towards an Analysis of Aesthetic Features of Public Policies

Abstract

Design is gaining popularity as a way to address complex social problems in various fields of practices. Strangely, public health which, by nature, is concerned by such kinds of problems, remains foreign to this way of thinking. Building on the increasing popularity of design in policy making, we stress that public health could also benefit from this conceptual yet pragmatic framework. To open a critical perspective about the potential of design for public health, we examine four design projects that address social determinants of health and whose outcomes promotes healthy living habits. Finally, we argue that the interest of design for public health lies on its concern for the users’ æsthetic experience emerging of its encounter with the touchpoints that embody health policies. This contribution ought to act as a stepping stone to open a debate about design as offering a critical perspective for the practice and study of public health.

Keywords: Public Health; User-experience; Aesthetic Experience; Social Innovation; Social Design

Since the turn of the 21st century, design has appeared more and more as an innovative approach to complex social problems (Manzini, 2015; 27e Région and Scherer, 2015; Miller and Rudnick, 2012). But this recognition of design for policy development, social innovation, and public services seems to follow a path that sets social design, public design, and policy design apart from the development of more traditional design fields, notably product design. For instance, although industrial design is fairly well recognized in the health sector where it has been called upon to contribute to the quality of health care facilities (Miller, Swensson and Robinson, 2012), delivery (Bak and al., 2014; Bate and Robert, 2007) and technology development (Altringer, 2010; Blakeney and al. 2009; Lehoux and al., 2011), design, or social design, has still to demonstrate its potential value in the public health sector. This paper aims at proposing a theoretical ground on which to build the contribution of design to this sector, defined as a practice which seeks to understand and favor the conditions of population health (Fassin, 2008). In this subdomain of the health sector, there exist a relatively large consensus about the structural determinants of health. These are usually summed up by fundamental causes like poverty, education, social capital, or living conditions (Link and Phelan, 1995). While shedding light on the quality of experience offered by public health policies and measures, a design approach to population health opens up a new perspective on some
lingering problems like the rise of STI among young adults, the increase of sedentarity, and food safety. It expands the specter of determinants considered in this domain, including factors that condition the very adoption, and use of devices, or, as Sen would put it (2012; Monnet, 2007), the conversion of a rightful access to healthy living into everyday practices. In that perspective, appealing to the concept of aesthetic experience (Forsey, 2013; Shedroff, 2009; Saito, 2007, Berleant and Carlson, 2007), seems an effective way to foster a fruitful cross-breeding between design, and public health measures and policy development.

Our proposal is based on the description of four students projects in social design. It refers to concepts and categories of realist and analytical æsthetic (Pouivet, 2006; Réhault, 2013) to define the qualities relevant to user-experience of public health policies. Design students projects are used as exemplars of devices that, through the qualities they display, support citizens access to healthy modes of living. The purpose of this analysis is to try and identify what constitutes the information base from which the qualities of an experience triggered by a policy can be derived, and to sketch a protocol through which qualities can be derived from such information base.

What is at stake here is twofold. On the one hand, there is a certain indeterminacy about what makes the quality of immaterial objects although research tends to put qualities—of services, of policies, of technologies—, as subjects of increasing interest (Bate and Robert, 2007). When trying to define what constitutes a responsible health innovation, one is forced to admit that what gives it its “responsible” character cannot be limited to the sole features of the devices that give it its concrete form (Findeli, to be edited). Incidentally, there is a correlative indeterminacy about the way we can assess such qualities as they unveils through user-experience of services or policies. On the other hand, there is still a vast array of questions about how and why many public health measures fail to reach their goal, outside of the usual financial burdens that limit their implementation.

In this paper we first examine how the attention given to user-experience can contribute to the expansion of the social scope of design. Second, we present why it seems relevant to bridge design with public health. We then present our analyses, pinpointing the “dispositional features” of different devices that offer the base for the emergence of an experience that displays a certain quality. Through our analysis, we try to offer an example of how design can build its specific contribution to public health.

2. User-experience expanding the social scope of design

Design is often looked at as a product centred practice where the goal is the enhancement or the shaping of beautiful, enjoyable and useful artefacts. If that might have been the general case 50 years ago, things have changed since (Vial, 2014; Fallan, 2010). At least over the past 30 years, designers shifted their professional activities toward lifestyle and user-experience through the design of information, services and systems (Redström, 2006). Bike sharing services are good illustration of that conceptual shift. In such projects the bike is not an end in itself, but merely a part of an ecosystem of touchpoints embodying a service that ought to see people adopt new living habits. Here, the habits are the definitive objects of design, and user-experience is at the base of the quality attributed to the service. Incidentally quality depends on
users’ capacities, values, biography whose understanding becomes a crucial part of design. This phenomenon has been characterized by Findeli and Bousbaci as a process that leads toward what they call the *eclipse of the object in design theory* (Findeli and Bousbaci, 2005). As a matter of fact, the designerly way of framing problems (Dorst, 2015; Schön and Rein, 1994; Simon, 1969) has yielded important insights on the role and importance of user-experience for the success of any policy or public services.

2.1 User-experience as a shared object of design and public health

Before discussing how to connect this contemporary conception of design with public health, we need to lay the ground and clarify through which door we see design entering the realm of a field in itself hard to construe. Indeed, public health contours are blurred by the fact that it is as much a science as a practice (Fassin and Dozon, 2001). When we look at the American Public Health Association (APHA) definition, we discover that any action that might affect or improve the environmental conditions of health or our understanding of them would be consider to be falling under the umbrella of public health.

*Public health promotes and protects the health of people and the communities where they live, learn, work and play.*

*While a doctor treats people who are sick, those of us working in public health try to prevent people from getting sick or injured in the first place. We also promote wellness by encouraging healthy behaviors.*

*From conducting scientific research to educating about health, people in the field of public health work to assure the conditions in which people can be healthy. That can mean vaccinating children and adults to prevent the spread of disease. Or educating people about the risks of alcohol and tobacco. Public health sets safety standards to protect workers and develops school nutrition programs to ensure kids have access to healthy food.*

*Public health works to track disease outbreaks, prevent injuries and shed light on why some of us are more likely to suffer from poor health than others. The many facets of public health include speaking out for laws that promote smoke-free indoor air and seatbelts, spreading the word about ways to stay healthy and giving science-based solutions to problem*.

1 In a nutshell, public health is concerned by the various determinants, material environment, social environment, individual behaviors, health care access, genetics, that affect people’s health (Lalonde, 1974).

Therefore, because design aims at shaping the material and social environment as well as the behaviors of communities, we argue that the quest for these features of a daily healthy

1 [https://www.apha.org/what-is-public-health](https://www.apha.org/what-is-public-health)
environment represents a shared object between design and public health\textsuperscript{2}. Yet despite having this common object, what is exactly the contribution of design to public health? What is the proper added value of design to the methods, approaches and knowledge developed in the field of public health? What are the contributing concepts that are at stake in this collaboration?

3. Research context

To explore the conceptual framework that supports the building of bridges between design and public health, we will examine four design diploma projects.

Using students' work is a common strategy in design research. For one, many emergent fields of practice in design stem from academic research and in that sense universities offer the only context where one can access the data needed to describe and analyse such practices and their outcomes. In fact, professional practitioners seldom accept to skew their practices to allow for the production of the necessary data or simply to let observational inquiry on their work be performed. Moreover, educational environment offers a very flexible context where ideal forms of practices can be experimented and assessed. Of course, such strategy entails a few shortfalls due to unrealistic experimental conditions. One might well argue that the stakes facing real practice can never be matched through educational curriculum. Also, by definition, students, however good they are, seldom show the same level of proficiency than seasoned professionals. Nevertheless, since our goal is exploratory, seeking how design can help ensuring quality of future public health policies, we are fairly confident that the somewhat artificial context of a school assignment does not disqualify our findings altogether.

The design projects discussed here are the results of the individual effort of four undergraduate students, at the University of Montreal School of Design, for their diploma project. The diploma project is a two semesters individual project where students must demonstrate that they have acquired the skills and knowledge to pursue a career as professional designers or graduate students. The diploma project is divided in two phases. During the first phase (research phase), fall semester, students are required to explore the scope and definition of their design problem and demonstrate their understanding of the topic, translating it in terms of design criteria. This first phase ends with a formal end of term presentation where a jury assesses the robustness of the process, as well as the student’s reasoning and methodology. For the second phase (development phase), winter semester, students are expected to engage in the development and validation of an actual solution for the identified problem.

At the start of the year, students propose a topic they want to explore but their proposition must respect a limited number of tracks defined by supervision teams, composed of full time professors assisted by research or professional fellows. One of the track offered to student at the School of Design is the social design track which is led by members of the Design and society research group. For the 2016 promotion, eight projects successfully took place in the social design track. Out of those eight projects, four are particularly insightful to stress the

\textsuperscript{2} The problem that remain nonetheless is that public health authorities don’t naturally go to designers to help them address their problems. Or if they do, it is with the limited understanding of design as form giving (gestaltung). But they do so mainly because the design community itself hasn’t made clear what is that they can bring to public health.
relevance of design in public health. We will here present and analyse those four projects to illustrate and discuss our first objective: what design has to offer to public health.

4. Research context

To explore the conceptual framework that supports the building of bridges between design and public health, we will examine four design diploma projects.

Using students' work is a common strategy in design research. For one, many emergent fields of practice in design stem from academic research and in that sense universities offer the only context where one can access the data needed to describe and analyse such practices and their outcomes. In fact, professional practitioners seldom accept to skew their practices to allow for the production of the necessary data or simply to let observational inquiry on their work be performed. Moreover, educational environment offers a very flexible context where ideal forms of practices can be experimented and assessed. Of course, such strategy entails a few shortfalls due to unrealistic experimental conditions. One might well argue that the stakes facing real practice can never be matched through educational curriculum. Also, by definition, students, however good they are, seldom show the same level of proficiency than seasoned professionals. Nevertheless, since our goal is exploratory, seeking how design can help ensuring quality of future public health policies, we are fairly confident that the somewhat artificial context of a school assignment does not disqualify our findings altogether.

The design projects discussed here are the results of the individual effort of four undergraduate students, at the University of Montreal School of Design, for their diploma project. The diploma project is a two semesters individual project where students must demonstrate that they have acquired the skills and knowledge to pursue a career as professional designers or graduate students. The diploma project is divided in two phases. During the first phase (research phase), fall semester, students are required to explore the scope and definition of their design problem and demonstrate their understanding of the topic, translating it in terms of design criteria. This first phase ends with a formal end of term presentation where a jury assesses the robustness of the process, as well as the student’s reasoning and methodology. For the second phase (development phase), winter semester, students are expected to engage in the development and validation of an actual solution for the identified problem.

At the start of the year, students propose a topic they want to explore but their proposition must respect a limited number of tracks defined by supervision teams, composed of full time professors assisted by research or professional fellows. One of the track offered to student at the School of Design is the social design track which is led by members of the Design and society research group. For the 2016 promotion, eight projects successfully took place in the social design track. Out of those eight projects, four are particularly insightful to stress the relevance of design in public health. We will here present and analyse those four projects to illustrate and discuss our first objective: what design has to offer to public health.

5. Method and Result

To analyse the students’ projects, we first looked into the work done during the research phase
to present the general problem tackled by students and examine, if not obvious still, what are the specific issues that correlate the projects to public health. Analysing the work done during the research phase allows us to reveal how those problems were framed into effective design mandates. Finally, through a close inspection of the development phase and of the final design solution of the students, we discuss the kind of experience engaged by those propositions and the different features they display. It is the experiential quality of those features that will serve as our unit of analysis to discuss, in the final part of the paper, the innovative contribution design may have on public health.

5.1 Community Kitchen in food desert community

*Problem setting and mandate*

This project considers the problem of bad eating habit. The project was set in the Montmagny region, a rural community in the Canadian province of Québec, where an important part of the population lives in precarious condition in a food desert area. This general problem translates in specific public health issues in the sense that limited commercial access to various produces makes it difficult to people and families to adopt good and healthy eating habits. The design mandate that emerged from this situation was to enable healthy eating habits amongst precarious population living in this rural food desert.

*Design solution*

To address that question the student developed community kitchen activities linked with a web-portal, where recipes are gathered, and a food guide (see figure 1) which, with the help of local social workers, would contribute to the dissemination of good practices at home while shedding light on locally available produces, and ways to use them. She posited that inducing alternative healthy culinary practices and food products in the community would increase people’s curiosity and eagerness to access a larger offering, pressing local grocers and producers to fulfill this new demand.
Features and qualities

The design of the community kitchen activities tries to underline a sense of discovery through pleasure, friendliness and positiveness. To achieve this, it makes use of an existing local organisation to build on current relationships and avoid paternalism. The touchpoints, using discreet and elegant graphic composition, are designed not to teach and tell what to do but to support people in embracing by themselves, and hopefully more sustainably, healthy eating habits. The whole of the proposition aims at accompanying a progressive empowerment of the population, cautiously harnessing local initiatives and existing networks of friendship.

5.2 Kick Sled as a device to empower active living despite winter's hindrance

Problem setting and mandate

This project look into the problem of Montreal’s citizen bitter relationship with winter seasonal reality. Such contempt of winter jeopardizes Montrealers Nordic culture and leads to wintering behaviors. A reality that translates into less active lifestyle, which is a significant issue for public health. Indeed, sedentarity has been identified as one of the main cause of chronic diseases like obesity, cardiac problem and diabetes. The design mandate identified seek to help city dwellers to embrace an active outdoor lifestyle in winter despite the numerous hindrances that comes along going out in the cold weather.
Design solution

The proposed solution is a kick sled sharing service, organised around the same principles as well know bike sharing services (see figure 2). The necessary equipments are installed in a community network of “white back alleys” where local dwellers can use the device for fun or running errands. Montreal urban morphology of central neighborhoods is characteristically organised around back alleys\(^3\). The service allows for a free and quick access to a seasonal active transportation device and multiply the opportunities for citizens to domesticate wintry weather. By favoring such an experience the proposition tries to offer the rightful condition to increase people’s readiness to adopt an active lifestyle all year round.

Figure 2: Rendering of project Ruelle et Luge

Features and qualities

People’s engagement in active lifestyle is promoted here through the design of a public service which favours playful and easeful experience of winter. Easefulness is achieved by a freemium-like business model that guaranty a free access to the base service. Simple, affordable infrastructures and derived products, like blankets, baskets, etc., help balance the budget of the service. The various touchpoints that compose the system, the sled, the signage, the brand, the communication, use vernacular formal language to boost the familiarity of local dwellers. All these efforts at making the system as transparent as possible are intended at empowering people’s in engaging in active living.

---

5.3 STIs Awareness

Problem setting and mandate

This project entitle NoTaboo addresses the rise of STIs among college students in Montreal. Indeed, college students face the risk of catching STIs because many still have unprotected sex, despite easy access to condoms. Researches (Whitfield et al., 2013; Buhi et al., 2009) identified the quality of information and lack of motivation to prevent STIs as sources of the problem. In design terms, this translates into a need to raise young adults awareness of STIs, making them realize the risk of their practices and the magnitude of collective unconsciousness.

Design solution

The solution developed in that regard was a public information display which exposes the practices, ideas, and prejudices about sex and STIs of students who confessed anonymously on an online survey platform (see figure 3). Presenting boldly, and publicly candid testimonies about sex and lay beliefs about STIs, was suggested as a way to fuel an ongoing discussion amongst peers, raising group awareness for issues related to sexual practices, and helping young adults to overcome shyness in front of legitimate institutional sources of information.

Figure 3: Prototype of the project NoTaboo
Features and qualities

To foster a sense of belongingness, the device tries to imitate a social network, but use a real public space to display students “status” and encourage face to face discussions. Going public strengthen the astonishment and the sense of awe necessary to bolster students reflection about their own practices and beliefs. The information shared by students are mediated by college social workers that stay available for whoever needs to untangle shaky beliefs about sexual practises and risks.

5.4 Food saver

Problem setting and mandate

People misunderstand how to correctly use refrigerators space and lacks knowledge about food conservation. Therefore, a lot of provisions ends up being wasted and the capacity to consume fresh and nutritious food decreases. The design mandate defined here consist in improving people’s understanding and know-how about personal food storage and preservation techniques.

Design solution

To overcome people’s unawareness of efficient food storage techniques, a new refrigerator layout is developed to make the proper storing of different foods easily intelligible and practicable (see Figure 4). Changing the way to store produces is used to increase people’s concerns about the values of food, inducing them to cook more and better.
Features and qualities

The layout proposed multiplies the number of compartments displayed by refrigerators, underlining the specific storage conditions of the different food items they may harbour. In this sense, it forces a kind of knowledge building that can take place despite user’s carelessness about food quality and preservation. However, this paternalism is subdued by the use of warm wood counter and curved edges. Transparency and whiteness help foster tidiness, self-awareness and dignity.

6. Discussion

Design contribution to the promotion of healthy behaviors was expressed in these projects in various manners. Yet each of them addressed a problem associated with the social determinants of health (Marmot & Wilkinson, 1999). As is usually the case with human-centred design approaches (Hanington, 2003), the projects stresses that experiential qualities of devices, emerging of what we called touchpoints, are essential triggers of new practices. Although insufficient in themselves, these qualities, like pleasure, easiness or awe, bring an essential contribution to the adoption of habits sought after by health policies. The reason we believe that design can bring about innovative solutions is rooted in this concern for users’ experience. Yet, such qualities of experiences, subjective as they are and based on an aesthetic appreciation of the world, usually fail to make their ways in the general economy that
arbitrates public health initiatives (Proulx, 2015).

We consider that the efforts our apprentice designers invested in “giving shape” to these devices, gaining insight about a problematic situation, pondering divergent answers to the situation, conjecturing a preferred user-scenario and refining it through iterative prototype testings with lay users, do offer a potentially critical perspective public health policies. Indeed, the design phase of any health promotion initiatives, may it be a service, a technical device, a communication campaign, should never be taken for granted. The design approach as a whole can yield valuable information about the issues at stake and the outcomes of a program or a service. The design process should be considered instrumental in the success or failure of any policy. Therefore, an understanding of this process, filled with contingencies and constraints, and framed by the subjectivity of stakeholders, should allow for a critical analysis of the field of public health measure.

7. Conclusion

This paper examined and discussed the potential benefit of design for public health, drawn by the recent expansion of the scope of design into social issues. If nowadays an appeal to design may sound obvious to enhance the quality of health facilities, delivery and technology development, it appears somewhat more difficult to establish the legitimacy of the approach for public health problems. We posit that detailing the process by which it becomes possible to elicit the experiential qualities of a policy or of a public health measure, can provide a sound theoretical base contributing to the acknowledgement of a design approach of public health. Advocating for a thorough analyses of the stuff of user-experience raises some interesting promises that allow to envision worthy research leads to open a critical perspective for the study and practice of public health.

Acknowledgements

We would like to thank our fellow students whose work provided us not only with the data but also with questions: Katarine Amyotte, Marie-Josée St-Hilaire, Éliane Perris, Thibault Illié, Élisabeth Thibault, Jessica Cloutier, Émilie Kingsley, Anne-Marie Lafontaine, Stéphanie Paré. We would also like to thank Olivier Payette-Demers and Alexandre Joyce whom intervene during the process as guest critics to the students. Their generous and insightful comments helped student development their projects and allowed us to further reflect on them.

Authors Biographies

Sébastien Proulx

Sébastien Proulx is Associate Professor of Industrial Design at The Ohio State University. He holds a PhD in Design and a Master of Applied Science in Design and Complexity from the Université de Montréal. He completed postdoctoral studies in public health at the Université de Montréal School of Public Health and a doctoral fellowship in moral sociology at the École des Hautes Études en Sciences Sociales in Paris.

Before joining the Ohio State’s Department of Design, Dr. Proulx was a lecturer and researcher at the Université of Montréal for 12 years. His research activities focus on social design and on designing for vulnerable people.

Philippe Gauthier

Philippe Gauthier is associate professor at Université de Montréal where he leads the Design et société research group. He was first trained as an industrial designer before undertaking his doctoral dissertation in sociology at the EHESS in Paris, France. He spent several years working as an independent research agent, examining the development and reception of normative devices — safety measures, public education programs, information — through a moral perspective. He now studies the role of experiential knowledge in the development of policies and public services.

Yaprak Hamarat

Yaprak is a designer and researcher who uses ethnographic approaches in several areas as ecology, citizenship, urbanity and health. Through her fieldworks focused on movements and materials, she studies the link between aesthetics and politics. After her studies in plastic arts, product and transport design, she worked in Turkey, France and Canada in art and design industry. She is now completing a Ph.D. dissertation in design at Université de Montréal and holds a teaching and research position at Université de Nîmes (France).
Surveying Stakeholders: Research Informing Design Curriculum

Andrea Quam, Iowa State University, Ames, USA, aquam@iastate.edu

Abstract
Fundamental to design education is the creation and structure of curriculum. Neither the creation of design curriculum, nor the revaluation of existing curriculum is well documented. With no clear documentation of precedent, best practices are left open to debate. This paper and presentation will discuss the use of a survey as a research tool to assess existing curriculum at Iowa State University in the United States. This tool allowed the needs and perspectives of the program’s diverse stakeholders to be better understood. Utilizing survey methods, research revealed the convergence and divergence of stakeholders’ philosophies, theories and needs in relation to design curriculum.

Accreditation and professional licensing provide base level of guidelines for design curriculum in the United States. However, each program’s curricular structure beyond these guidelines is a complicated balance of resources, facilities, faculty, and the type of institution in which it is housed. Once established, a program’s curriculum is rarely reassessed as a whole, but instead updated with the hasty addition of classes upon an existing curricular structure. Curriculum is infrequently re-addressed, and when it is, it is typically based on the experience and opinions of a select group of faculty. This paper presents how a survey was developed to collect data to inform curricular decision-making, enabling the reduction of faculty bias and speculation in the process. Lessons learned from the development of this research tool will be shared so it might be replicated at other institutions, and be efficiently repeated periodically to ensure currency of a program’s curriculum.

Keywords: education, curriculum research, curriculum design, undergraduate design curriculum

When a college or university design department looks to re-examine or develop a graphic design curriculum, there are few vetted resources to refer to. A common first step is the benchmarking of the competing and parallel curriculum at other institutions. This was the first step undertaken for the survey addressed in this paper. It is a challenging undertaking, as most schools do not publish curricular structure and objectives outright. Instead, they can be pieced together through course schedules and curriculum degree sheets published online for their students. While a valuable and insightful endeavor for a means of comparison, this research process does little to inform a department toward their own curricular direction. Individual curriculum is greatly driven by each program’s unique situation of how they are housed within their larger institution and their balance of resources, facilities, faculty and stakeholder needs.

Any program working towards the validity of accreditation will first seek out a national accrediting body for a basic understanding of required criteria for this process. In the United States, this organization is the National Association of The Schools of Art and Design.
Founded in 1944, NASAD is an organization of schools, conservatories, colleges, and universities with approximately 352 accredited institutional members. It establishes national standards for undergraduate and graduate degrees and other credentials for art and design and art/design-related disciplines. It also provides assistance to institutions and individuals engaged in artistic, scholarly, educational, and other art/design-related endeavors. NASAD standards concerning graphic design are developed in consultation with the national professional organization for graphic design, the American Institute of Graphic Artists (AIGA), and approved by the accredited institutional members of NASAD. The NASAD standards mandate an effective relationship among goals, curricula, resources and projected competencies for graduates. Undergraduate graphic design programs are presented as majors by meeting NASAD standards for professional degree programs only if they have demonstrated that students are expected to gain the common body of knowledge and skills before graduation. NASAD requires that approximately 65% of the total program be devoted to studies in design, design history, art, and related areas, and at least 25% of the total program is to be devoted specifically to studies in graphic design. This establishes a basic structure for curriculum to follow. However the content, time on specific tasks, expectations and required proficiencies upon graduation must be uniquely reflective of individual programs and their stakeholders (NASAD 2010). How then, is a program designing or redesigning its curriculum to determine its objectives and needs beyond the structure set forth by an accrediting body—in a manner free of faculty bias and speculation?

Presented in this paper is one Midwestern University graphic design program’s development of a survey tool to inform a re-assessment of the curricular structure—aft the benchmarking of comparative programs, the consultation of an advisory board and consideration of the foundational requirements of accreditation. By investing in research, the unique needs and opportunities can be revealed for individual programs, and it is argued that research of this nature is an often-overlooked component of curriculum development.

**Literature Review**

In preparation for the development of a survey tool to inform graphic design curriculum, a literature review and investigation into the proper and effective development for a survey was completed. Designing a survey to yield high quality usable data and achieving a high return rate is not as easy as it might appear. (Boynton 2004) Surveys are frequently used to collect research data. As a research tool, surveys can provide reliable data to answer a research question. With careful planning, surveys can yield high quality data, achieve good response rates, and provide anonymity. The latter encouraging more honest answers than, for example, interviews. This can help to reduce bias (Marshall 2004). As with all research instruments, there are advantages and disadvantages. Advantages include that they are relatively inexpensive to produce and provide high-volume, time-efficient data collection. Disadvantages include the potential cost of data distributions and collection (depending on how distributed), inaccurate, incomplete or mischievous responses and low response rates (Grimmer and Bialocerkowski 2005).

All surveys should include an introduction, which states the survey’s purpose and the research question. It should also provide the principle researcher’s contact details, evidence of ethics
committee approval, the estimated time required for completion, and assurances of
respondents’ anonymity. Care should also be taken not to inadvertently collect information
that could identify respondents. To maximize response rates, surveys should take less than 10
minutes to complete (Staples 1991). Before executing a survey, a thorough literature review
should be conducted to ensure there is not an existing standard survey on the research topic. If
a new survey instrument is required, survey content and question construction should be based
on defensible qualitative data, which reflect the perspective of individuals representative of
the population of interest (Rice and Ezzy 1999). When all possible answers are unknown,
respondents should be given the option of an ‘other’ category which allows them to reply
using free text. Analysis should consider the frequency of ‘other’ responses and the themes of
the free text answers. This provides important information regarding the research question,
and enhances future survey construction (Grimmer and Bialocerkowski 2005).

Questions in surveys should be short and focused, consisting of generally twelve words or less.
The more structured the questions are, the easier they are for the researcher to interpret, as the
data produced will be quantitative (in other words information that is quantified and thus
numerical). To yield qualitative data (non-numerical observations and narrative data) a high
proportion of open questions must be asked. There are a range of question types that might be
used in a survey such as: open questions (those where the expected response is in words);
closed questions (where a respondent is offered a choice of alternative responses); quantity
(where the response is a number); list (where the respondent can select more than one
response, as the responses are not mutually exclusive); category questions (where there is a list
of mutually exclusive categories); ranking/scaled (an example is the Likert scale where the
respondent chooses a ranked option from a list, indicating their degree of agreement or
disagreement with a statement); and grid questions (where more than one dimension is
measured). There are also key things to be avoided in survey questions such as: hypothetical
questions, imprecise questions, ambiguous questions, assuming questions, double questions,
leading or loaded questions, presuming questions, and memory questions (Marshall 2004).
Sequencing of the survey questions is important to increase response rate, and it is better to
start with easy, non-threatening, non-sensitive questions. Filter questions are appropriate where
it is not necessary for all respondents to answer all questions (Marshall 2004).

Piloting should occur before the questionnaire is administered to the research sample to ensure
the reliability and validity of the questionnaire. Reliability is the degree of consistency or
dependability with which the instrument measures the attribute it was designed to measure.
This is to ensure that the differences in results come from differences in respondents, not
differences in how the question was understood. Validity is the degree to which the instrument
measures what it was intended to measure. An unreliable survey cannot be valid; however, a
reliable survey can be invalid. The extent to which the sample size represents the population is
a factor in assessing the validity of a study i.e. the extent with which the results can be
generalized to other samples or situations. (Marshall 2004).

While surveys offer a valuable data collection method, they require careful consideration at
the design, application, and analysis stages to ensure reporting of valid and reliable data
from a sample of respondents who are representative of the population of interest (Grimmer
and Bialocerkowski 2005).
Research Methods

For this research, a survey for the stakeholders of an undergraduate curriculum in graphic design was developed utilizing Qualtrics. This web-based software, licensed by many research universities in the United States, allows users to create surveys and generate reports without having any previous programming knowledge. Through the use of Qualtrics as a survey tool, both qualitative and quantitative data was collected anonymously in aggregate from design students, graphic design educators, alumni and practicing professionals. These key stakeholder groups were determined to be those most invested in a typical design program’s curriculum. This was established through the consensus of an ad hoc undergraduate curriculum committee, consisting of ten of Iowa State University’s graphic design faculty.

Informed by the literature review, an introductory statement explaining the research question, the researcher’s contact information, time estimated to complete the survey, internal review board (IRB) approval of the survey, and assurance for the anonymity of respondents was placed at the front of the survey. Content and questions for the survey were developed by a faculty member within the program and vetted through program faculty and small focus groups of students and processions. The final version of the survey was distributed to current students through classroom instructors. A snowball sampling of design educators and practicing professionals was attained through the distribution of the survey link by e-mail to acquaintances and alumni lists. They were asked to further share the survey link on social media to acquire an extensive, national and international sampling. Approval was applied for and acquired from Iowa State University’s Internal Review Board (IRB), so all data collected might be published for the benefit of the academic community. After a two-month distribution cycle the survey received over 250 responses.

The survey was structured in a manner in which the response to the first question (a filter question) determined what kind of a stakeholder they were (student, educator or professional) and directed them to a bank of questions relevant to their investment in graphic design curriculum. Survey research suggests surveys should take 10 minutes or less to complete; therefore, each set of stakeholder questions were kept to less than a dozen questions to ensure respondents could take the survey expediently. (Staples 1991).

Stakeholders were asked individual questions relevant to their investment and perspective of the curriculum, with the exception of two common questions which everyone taking the survey was asked. Questions regarding the perceived weaknesses and strengths of the existing curriculum were the two common questions asked of all stakeholders. The responses to these common questions were especially valuable to ensure faculty were eliminating assumptions and biases as they addressed the existing curriculum, and make certain proposed changes were based on evidence. This also revealed minor, yet surprising differences in the perceptions of strengths and weaknesses among the three different stakeholder groups.

The survey was crafted to collect both qualitative and quantitative data, and had a blend of open, closed, list and category questions. Additionally, filter questions were utilized, so
respondents were directed only to questions necessary and appropriate to them.

**Discussion**

Of the three stakeholder groups responding to the survey, students were the largest with a total of 145 student replies. The next largest category to respond was professionals with a total of 78 filling out the survey, followed by educators with 36 participants.

**Student Respondents**

Of the 145 student responses, 69 were freshman that had not yet gained entrance to the program. The remaining 76 responses were from students currently in the program: 19 sophomores, 20 juniors, and 33 seniors. All student stakeholders were asked if they had applied to other schools when considering majoring in graphic design to aid in determining the program’s primary competition. A slight majority of 56.20% had considered another school. When asked the identities of other schools considered by these students, researchers were able to discern that geographic location seemed to be a large determining factor. Of the 54 other design programs listed by students, the top 10 most commonly mentioned institutions were in the same or neighboring states.

Freshman (not yet participating in the curriculum under study) were asked what were their anticipations of the curriculum they hoped to enter in the near future. While this question was an open question (eliciting qualitative data), researchers were able to group responses into common themes. These groupings determined a majority of freshman expected a curriculum focused on technology and software skills to prepare them for professional practice or advanced learning.

The rest of the enrolled student stakeholders answered questions focusing on a range of topics. Questions addressed their perception of the current curriculum and proposed format changes to the curriculum. Two open-ended questions were also used to address expectations and give students the opportunity to express additional thoughts or concerns not covered in the survey questions.

The upperclassman stakeholders’ first question addressed their perception as to whether the current curriculum was adequately preparing them for their future pursuits. While a majority (74.65%) replied ‘yes’ the curriculum was fulfilling their needs, a concerning 25.35% replied ‘no’ it was not. With a quarter of the respondents replying negatively, concerns that a reassessment of the curriculum was unnecessary were quelled.

The survey also provided the opportunity to ask students their preferences and perspectives of topics covered in the curriculum and what they felt might be the most applicable means of delivery. Addressed in these questions were the standing arguments of teaching technology within a graphic design curriculum and whether or not resume and portfolio preparation should be a part of the formal curriculum. Only 8.20% of students responding to the survey felt that technology should *not* be integrated into the design curriculum. This small percentage
felt technology should be learned outside of the curriculum through online means such as Lynda.com. This was an important understanding; it highlighted the importance for faculty to include technology as a part of their design studio instruction within the curriculum. This aspect of the survey was additionally informative, as many of the faculty were in favor of eliminating classes which taught technology, and instead urging students towards online tutorials.

Understanding that this is not a preferred instruction method for the students highlighted a key discrepancy between the trajectory of the curriculum and student stakeholder needs and desires. When the question was posed regarding the preparation of business papers and portfolios integrated into design curriculum, only 9.84% of the responding upperclassman students felt it was not necessary to include topics of this nature. In assessing the curriculum, faculty were divided on the necessity of including this type of instruction in the curriculum, while the stakeholders it served found it important. These survey questions helped to resolve the on-going debates among the department faculty regarding integrating technology instruction, portfolios and professional presentation into the existing class structure. In these instances research data clearly highlighted discrepancies between faculty assumptions and student stakeholder needs and desires.

The question series for upperclassman student stakeholders also collected qualitative data regarding their hopes and expectations with the curriculum. A majority of the qualitative comments collected could be organized into a common theme, which culminated in focuses on careers and being well prepared for professional practice. This was closely followed by comments collectively themed as the acquisition of graphic design knowledge and the specific types of design projects they hoped to experience in the curriculum.

**Educator Respondents**

Educators were the minority of stakeholders responding to this survey, with only 36 filling out the survey. The first question asked of the educators was one to ascertain their level of experience as a design educator. A majority of those responding (36.11%) were fairly new to the profession with 4–9 years of teaching experience. Those with the least amount of teaching experience (1–3 years) and the most amount of teaching experience (30–40 years) were the minority of respondents. (table 1)

Educators were asked where they received their graduate degree in order to ascertain the range and variety of education experiences and philosophies influencing the respondents. While some omitted a response to this question, it was determined a minimum of twenty
different graduate programs were represented in the responding educators. While the majority attained their graduate degree from public universities, a blend of public and private institutions was represented.

Respondents were asked an open question regarding what they felt were the key aspects making the curriculum they were currently teaching effective. While open ended, a majority of the qualitative comments could be combined under thoughts related to how their courses and programs were structured, as well as references to specific types of projects within their curriculum. In the next largest grouping of themed comments from this question, educators specifically referenced a curricular focus on knowledge, skills, problem solving and critical and strategic thinking.

When asked an open ended question regarding what was integral for graphic design education programs to include when structuring curriculum to meet future needs, faculty responses were divided and the qualitative feedback on this question was not as easily categorized. The top themes, most evenly distributed with four to five educators referencing each of these, were: a focus on thinking and problem solving, a focus on digital and interactive design, a focus on design fundamentals and foundational skills, and a focus on curriculum that was balanced and diversified. Categories closely following these, with three educators referencing each were: a collaborative, networked focus; a focus on experimentation and curricular flexibility; a focus on users and human behavior; and a specific focus on industry.

Professional Respondents

78 professionals responded to the survey. The first professional question asked was one to ascertain their level of experience as a practicing professional. 31.17% of the professionals responding had practiced for a decade or more, this was closely followed by those respondents who had been practicing less than a decade (4–9 years) with 27.27% practicing within that time frame. The fewest respondents (3.90%) had been practicing for the longest time (30–40 years) and the second smallest sampling at 11.69% had been practicing for the least amount of time (1–3 years). These results reveal a majority of those providing responses to the survey had a good amount of experience and were potentially in a position to influence the hiring process of recent graduates.

Overall percentage does not total 100% because some individuals did not respond to this question.

Professionals responding to the survey were also asked about the type of design work they did. This question sought to provide information ensuring our curriculum is accurately
preparing students for the nature of work they would be facing immediately upon graduation as well as into the future. The faculty perception was the existing curriculum was in need of a stronger digital focus; however, faculty were divided as far as how to approach this and whether it should be a balanced or primarily digital focus. Responses from the professionals indicated 27.63% of the professionals did an equal combination of print and interactive, followed by 17.11% saying they did a majority of print. This helped faculty come to a consensus that print still has a role to play in the graphic design industry and therefore graphic design curriculum. However, with only 9.21% saying they produced almost entirely print design, and 15.79% of the respondents stating their work was almost entirely interactive—there was clear support from this survey for the belief of digital gaining momentum well into the future within the graphic design industry. It should also be noted that 11.84% indicated a majority of their work was interactive, and typical industry forecasts predict this number is only going to grow, not diminish. These findings are all valuable in crafting a sustainable and forward-looking curriculum.

Professionals familiar with the existing curriculum were asked to address curricular specifics once they were identified by a filter question. If they were alumni of the program, they were asked if they felt they had been adequately prepared by the existing curriculum after working within the industry for several years. A majority did feel they were prepared, with 67.31% indicating ‘yes’ and 32.69% reporting ‘no.’ While rewarding to hear the majority was affirmative, 32.69% responding ‘no’ leaves room for improvement for the curriculum. Those responding ‘no’ were then filtered to an opportunity to delineate their concerns. These responses were beneficial to further focus the potential opportunities for overall curricular improvement. Many of the qualitative responses referenced and reinforced the opinion of a need for a stronger focus on digital design within the curriculum. While not an unexpected result from the survey, it was a useful one in supporting what faculty already believed to be a curricular deficit.

In summation, professionals were asked two questions regarding the most decisive factors in their hiring process of recent graduates and their perception of what will be the most important skills they should have in the future. While both were opened-ended questions allowing for qualitative answers, the responses from professionals contained a large degree of consensus and were quite readily grouped into similar ideas and themes. In response to important future skills for graphic design graduates to have, the clear majority fell into three categories: strong thinking abilities (problem solving, strategy and creativity), adaptability, and digital knowledge. Highlights and themes of communication and leadership abilities as well as user experience were the next common response groups.

In response to the most decisive factors in their hiring decisions, an overwhelming majority of the comments (49 of the 78 respondents) stated that people who were ‘easy to work with’ was the key determining factor. Comments highlighting this quality mentioned characteristics such as: positive attitude, good personality, professionalism, respectful, and able to take criticism well. This overwhelming consensus was followed closely by two other categories themed as: thinking abilities (problem solving and critical thinking) and willingness to learn. While it is clear all of these qualities are valuable and sought after in a future employee or co-worker, it was an eye-opening revelation. This is especially significant in a profession where the
presentation of a strong body of work in the form of a portfolio is the well-established foundation of the interview process.

The common questions

There were two survey questions that were commonly asked of all three stakeholders (student, educators and professionals alike). These two questions asked those familiar with the existing program to select categories of strengths and weaknesses within the existing curriculum. These questions revealed whether the perceived strengths and weaknesses aligned among the stakeholder groups and within each group. It was of interest to see that for both questions (regarding the strengths and weaknesses of the existing curriculum) the educator stakeholders varied the most among themselves, while the student and professional stakeholders had more overall internal agreement. It is hypothesized this may be a reflection of educators’ specialized areas of interest and research and a viewing of curriculum through that lens. Regardless of the reason, it further points to the need for research to be a foundation for curricular directions, rather than being built upon individual educators’ opinions and individual philosophies.

Research limitations and future directions

This survey was established as a foundation for future iterations to routinely take place, ensuring the currency and maintenance of the curriculum. Results from this survey will be used to craft a follow-up survey every two to four years to evaluate progress in the curriculum and ensure currency. Many of the open questions soliciting qualitative comments in this survey (whose responses were categorized into themes) will evolve into category questions in future iterations of this survey, allowing for more definitive data.

The predominance of open questions was one limitation of this initial version of the survey. However, it was beneficial to first explore key questions of this survey in an open manner to ensure a proper category selection in future iterations. It might be best to consider this initial survey an expansive test pilot or focus group survey.

The omission of the survey to collect geographic location information from the educator and professional respondents was another limitation of this research. Because this information was not collected, it limits the ability to concretely determine how widely distributed the survey was. Future iterations of this survey intend to collect this information, and those wishing to replicate this survey should consider including this key information from demographics surveyed.

Of the common questions asked across all stakeholders (the questions regarding strengths and weaknesses of the existing curriculum) it would have been beneficial to have respondents rank the strengths and weaknesses of the existing program, rather than merely select categories of each. This would have ensured not only an understanding of strengths and weaknesses, but also a clear prioritization of them. However, regardless of this limitation, these questions provided an informed consensus on existing curricular strengths and weaknesses—rather than merely reflecting opinions of the faculty charged with reviewing the curriculum.
Conclusions

The results of the survey were valuable in resolving bias and misconceptions held by faculty responsible for the assessment and crafting of the curriculum. It changed the intended delivery methods for both technology, portfolios and business papers in the curriculum. Originally the intended delivery methods for these were based on faculty preferences. The summarization of the survey data provided quantitative consensus to support arguments for student stakeholder needs and desires instead of qualitative speculations. Conducting the survey and reviewing the results with the entire faculty body helped move the discussion from faculty preferences to the needs and desires of student stakeholders. The research also helped to move curriculum discussion from idealistic to a combination of idealistic and pragmatic when survey responses from professionals were presented. When forecasting the future, professional and educator responses were overall in agreement, but key differences in secondary levels of importance encouraged discussion which helped to fine-tune additional curricular focuses and details.

With the use of research and therefore more objective information to base decisions on, faculty and departments are able to more efficiently come to a consensus on the direction and needs of curriculum. As Adrian Shaughnessy stated in an October 2014, Computer Arts magazine article, “Design education at the university level is like a slightly wonky triangle. It has lots of students at one point, far fewer educators at another point, and what academia likes to call ‘industry’ at the third point. Each looks for something different, but each is dependent on the other to find it.” He goes on to state that hovering over all of these is the storm cloud of tuition fees. Shaughnessy points out that because tuition fees are now eye-wateringly expensive, new marketplace logic permeates all aspects of higher education. As a consequence of fees and the world changing at a supernova speed, design education is going through a period of tumultuous internal and external scrutiny, triggering many questions (Shaughnessy 2014). This scrutiny demands design programs develop mechanisms to keep them current and competitive. Utilizing research tools, such as surveys, is one effective means of ensuring curriculum evolves in a manner based on a solid foundation, rather than speculation. When a survey is created with consideration for factors such as sequencing, question types, and survey length they can produce strong response rates. With sound data from strong responses, curricular decisions may be made in a logical and informed manner. This helps curricular considerations move beyond baseline accreditation standards, to develop objective understandings of their individual program’s needs and specific circumstances.

Author Biography

Andrea Quam
Ms. Quam is an assistant professor of graphic design at Iowa State University’s College of Design. In 1997 she received a BFA in Graphic Design from Iowa State. She has over 10 years experience practicing professionally as a multimedia and print designer. In this time she worked with a range of clients including: McGraw Hill, Ford, Principal Financial Group, General Electric, Elsevier Science and Meredith Corporation. She received her MFA in graphic design from Virginia Commonwealth University in 2008.

Andrea teaches at all levels of Iowa State’s graphic design program. Her work has been published and exhibited regionally, nationally and internationally. She has presented papers at the Design Research Society (DRS) Cumulus Conference, Southeastern College Art Conference (SECAC), Hawaii International Conference on Arts and Humanities (HICAH) and the University and College Designers Association (UCDA) Conferences.

Her research interests focus on the relationship between design education and professional practice and how this influences design pedagogy. Andrea’s recent work includes the development of a card-based system for teaching design fundamentals in an outdoor classroom, investigations into ethnographic and generational research methods, and transformations in digital publishing.
(Un)intended Value Implications of Graphical Representations of Data

Milena Radzikowska, MDes, PhD, Mount Royal University, Calgary, Alberta, mradzikowska@mtroyal.ca

Stan Ruecker, MDes, PhD, University of Illinois, School of Art and Design, Champaign, IL, USA, sruecker@illinois.edu

Abstract

The design of meaningful graphical objects to represent collection items must balance the following: amount of useful information that can be communicated through the object’s graphical form, meaningful graphical difference between individual items or groups of items, and restraint in form complexity to allow for the simultaneous display of numerous collection items at a small size. How the user interprets difference and sameness and, more importantly, whether the user attaches hierarchical value to the emergent categories, may play a significant role in determining whether that user focusses attention on one set of data over another, on one set of processes over another, and ultimately, on one set of tasks over another. This paper examines the significant consequences for the understanding of the user resulting from representation of data, files, and other objects in a human-computer interface (HCI), and proposes that new approaches may be indicated, given the growing complexity of what is being represented and how what is represented can be used.

Keywords: visualization, HCI, design

Introduction

In his 1986 classic, the Whale and the Reactor, Langdon Winner argues that it is important to interrogate the political implications of design. He points out, for example, that the low clearance of bridges, over parkways in Long Island, New York, were a deliberate choice made by city planner, Robert Moses, to make the park inaccessible to lower-income groups, who relied on public busses for transportation. In a similar vein, Victor Papanek in his 1973 edition of Design for the Real World, calls design in the age of mass production “the most powerful tool with which man shapes his tools and environment (and by extension, society and himself)” (14), then accuses it of putting “murder on the level of mass production” (14). He states that, while advertising designers persuade “people to buy things they don’t need, with money they don’t have”, industrial designers create unsafe, unnecessary, “tawdry idiocies” to be “hawked by advertisers” (14). As evidence he points to the industrial process and product-use that create exorbitant waste material, pollute our air and water, and are capable of causing injury and harm to a cross-global population.

Though most human-computer interfaces (HCIs) are not the outcome nor the mass producer of industrial design, many enable mass production, distribution, purchasing, and obsolescence on
a scale that does not have its equal in a physical counterpart. Take amazon.com as an example. In 2014, Amazon reported almost US$89 billion in net sales, with almost 114,000 total office and warehouse units, 181.12 million unique monthly visitors, and 305,258,547 unique products (Statista, 2015). While Amazon is not responsible for manufacturing all these products, the company and its website do provide unprecedented access to them in terms of availability and lower cost, with little substantial information regarding the products’ origin or value, and no information regarding the multi-dimensional, short, medium, and long term impacts of its purchase.

Information visualizations (both static and interactive) use some type of graphical representation to display items in a collection. For example, The U.S. Gun Deaths project (Kirk, Kois, and @GunDeaths) uses curved, moving, coloured lines to display length-of-life projections for people who were killed by a gun (see Figure 1). The Out of Sight, Out of Mind project (Pitch Interactive) also uses curved, moving lines, but this time to display drone strikes on Pakistan (see Figure 2). In both designs, data took an abstract yet metaphorical form, though with very different rationales: (1) line length as time passing and line length as distance travelled; (2) color and shape as life lived vs. life that could have been lived (orange and white) and strike vs. life lost; and (3) position on screen as life arch vs. burial.

Figure 1: U.S. Gun Deaths (Kirk, Kois, and @GunDeaths).
Building on past work in rich-prospect browsing, feminist HCI, and text visualization, this paper is a theoretical reflection on the political nature of graphically-represented data, and aims to explore three questions: (1) What constitutes meaningful representation of items in a collection; (2) What are the potential implications (consequences) of different kinds of representations; and (3) What is the value of sameness or difference in graphical representation?

**Relevant Literature**

In data visualization, designers make a choice, first, what type of graphical object – in Peirce’s terms an icon, index, or symbol – will stand in for the items found in a particular collection. Second, they consider the details of form. Such representation may, in some instances, be closely evocative of the collection item’s original form (e.g. a thumbnail photo may stand in for a larger version of the photo), or the form may be arbitrarily assigned (a line stands in for a person’s life span). The Mandala Browser, for example, (see Figure 3) shows a macro view on the entirety of Romeo and Juliet, with each speech in the play displayed as one, color-coded dot (http://mandala.humviz.org). When a user clicks on a dot, she can read the corresponding speech in a text frame located to the right of the browser. The graphical representation (dot) of each speech is arbitrary. Using Peirce’s terms, this interface uses symbols as graphical representations of data: dots and Shakespeare have no natural connection to one another.
In another example, the Paper Drill interface displays an article’s citations (items in that collection) using a gridded series of coloured squares, with each square representing one citation source and the colour the centrality of the article in terms of what it cites and how often it is cited by the other papers (Ruecker et. al., 2011). The squares have been chosen by the designer to represent a “heat map” of articles in the collection. In this case the connection between a square, its colour, and the text is indexical—defined by some sensory feature. In the case of the Paper Drill, the colour of the square is representative of the level of “hotness”, or popularity, of that paper within the collection. Popularity is determined by how many citations the papers it cites get and how many papers also cite it.

The additional benefit of the representation found in the Paper Drill interface, is that the small geometric shapes allow for a prospect view on all the items in a very large collection (Figure 4 shows 1,666 citations by 36 authors).
For some collections, on the other hand, an iconic item representation may be not only possible, but preferable given the nature (and size) of the collection and the types of tasks that are likely to be performed with it.

In the Slot Machine interface (see Figure 5) the first column features the entirety of Gertrude Stein’s *Making of Americans* (Stein, 1995) in micro text, with subsequent columns generated based on a user’s search of a repeated phrase. All columns are aligned along a reading slot that magnifies the repeated phrase and its immediate context. The Slot Machine is a good example of an interface where there is a close connection between the item in the collection (the novel) and its graphical representation (a column made of a micro text version of the novel) (Radzikowska, et. al., 2007). In this case, the close connection in representation (Peirce’s icon) is of benefit since it facilitates an exploration of the text across and within multiple contexts. At the same time, a micro text representation of a novel (even one that is not 1,000 pages in its original form) requires the use of specialized technology, such as a wall-size display, making such representation possible but impractical (Radzikowska, et. al., 2007).
In our previous work on rich-prospect browsing (Ruecker et al., 2011), we began discussing ways that the user’s current task may benefit from a dynamic change in the representation of the items. For example, being able to rotate an object in order to see it from all sides (Peirce’s icon) might be crucial for some tasks, while a simple text label (Peirce’s index) for the same object might be sufficient for others, and for still other uses a dot (Peirce’s symbol) might be enough. Our argument is that the interface should do everything possible to provide the user with options for manipulating a display showing all items in the collection, since it is not possible for the designer, or the user, to know in advance all of the tasks that the user will want to perform.

**Research Methods**

To interrogate graphical data representation we must first accept three premises: (1) that a designed artefact can hold some kind of argument; (2) that design thinking and making contribute to human knowledge; and (3) that designed artefacts are complex agents that act upon our world.

In design the creation of an artefact can be, in and of itself, a way to formulate an argument about designing similar artefacts. This idea, proposed by Galey and Ruecker (2010), is based
on what they see as theoretical affinities between design and book history scholarship, experimental interface design sharing much in common with the emerging practice of peer-reviewing digital objects in scholarly contexts. Both design and book history engage in interpretation and in making and both, if properly contextualized, “can contribute to a theoretical framework for new questions” (Galey and Ruecker, 2010). Similarly, Bardzell argues that a design can function as a form of research. He builds on work in aesthetic cognitivism, and asserts that design, in its ability to tell us something about reality, contributes to human knowledge (“Design as Inquiry”). The critical analysis of designed artefacts “positions us in a potent space between the past and the future. Failing to recognize design as a hermeneutic process means failing to understand how our inherited cultural record actually works” (Galey and Ruecker, 2010). If we are to conduct a thorough critical analysis, we must consider designed artefacts at the macro, meta, and micro levels—each artefact is (1) a collection of multiple, designed parts; (2) a totality that is something far more complex than the additive nature of its individual components; and (3) is inherently contextual and context-dependent (Radzikowska, 2015). That design matters, that it exists, that it will have an impact, and that this impact can be for the positive has, more recently, entered the multi-disciplinary discourse. Fuller (2008) acknowledges that “objects, devices, and other material entities have a politic—that they engage in the arrangement and composition of energies, allow, encourage or block certain kinds of actions” and writes that “these concerns have also more recently been scrutinized by the interdisciplinary area of science and technology studies” (7).

Discussion

1. Meaningful Representation

What does it mean for graphical representation to be meaningful? Perhaps surprisingly, Peirce’s categories are orthogonal to this question. Document icons, for example, though graphical are often not very meaningful, especially in the context of other, similar icons—when used to represent hundreds or even dozens of documents, they become “a complex pattern composed of identical elements” (Ruecker, 2003). They convey the size of the collection—I have several dozen annotated articles on feminism—but very little information about the unique characteristics of the items contained within the collection (see Figure 6).
What constitutes meaningful graphical representation depends, primarily, on what kinds of knowledge we expect to extract from its browsing. For example, one shopping cart icon is meaningful by itself, signifying online purchasing. In a collection of shopping cart icons, we may be able to explore the different ways icons have been drawn to represent online shopping, their colour structures, that some are carts and some bags (see Figure 7).

Figure 6: In a file folder, textual labels need to be added to differentiate one file from another; suggesting that the graphical representation alone is insufficient. In fact, filenames are a required component.

Figure 7: Collection of shopping cart and bag icons
(http://www.intersmash.com/300images/images/carts.gif)
If we have additional information attached to each graphical representation—country of origin, type of online shop where it is used, attributes of its designer—our exploration can become much more meaningful. We may be able to consider cultural or social trends, change in design over time, and much more. In another example, imagine that we are looking at images of sheep, from a farm that produces merino wool to be made into sweaters. If our hope is to see photos of Betsy (one specific sheep) and her human and animal family but we are, instead, shown generic sheep-like icons, we will be disappointed. If, instead, we are exploring sheep types found in New Zealand’s wool industry, illustrations that are based on but that abstract sheep categories may be more informative.

The design of meaningful graphical objects to represent collection items (in data visualizations, for example) must balance the following: amount of useful information that can be communicated through the object’s graphical form, meaningful graphical difference between individual or groups of items, and restraint in form complexity to allow for the simultaneous display of numerous collection items at a small size. How we interpret difference and sameness and, more importantly, whether we attach hierarchical value to the emergent categories, may determine whether we place emphasis on one set of data over another.

Whether we consider a graphical representation meaningful, may or may not have anything to do with its visual complexity. For example, an abstract line may have intended meaning (life lived) and emotional impact (life prematurely cut short); while a photograph (which is far more complex in terms of visual information) may simply intend to say faculty member (see Figure 8). We must, though, differentiate between intended and unintended meaning. In the *Faces of Innovation* example as shown in Figure 8, the intent of the designer may have been to simply display MRU’s researchers and make them recognizable to others through the use of portraits instead of abstract head icons. However, by looking at the entire collection of portraits, we may be able to conclude that MRU has a predominantly Caucasian population. Depending on the context of viewing (as a potential hire, for example) such information may be quite meaningful.
2. Implications & Consequences

In our recent work on visualization for decision support in the Alberta oil industry, the results provided to the user (the data that becomes part of a collection and, subsequently, a visualization) are highly dependent on the specific choices of variables, which in this context are referred to as constraints\(^1\). Traditionally, the choice of constraints that can be manipulated by the user consists of processes, parts, and materials. For example, one constraint might consist of the number of trucks, while another is the number of barrels of refined oil. Figure 9 shows one design solution to the problem of graphical representation: a gear shape represents connection (a cause and effect relationship between parts); a solid gear represents a constraint; and a pie chart gear represents the solution to a decision problem. Thus, in Figure 9 we can see four constraints at play to generate a solution, and a separate solution (possibly made in the past) that isn’t currently under consideration (the non-geared pie chart). Coloured gears signify liquid ingredients, while coloured and textured gears signify dry ingredients. This distinction provides an additional layer of information and a greater range of options for colour coding.

---

\(^1\) Our industry partner asked us to use ice cream manufacturing instead of oil refinement and extraction as our scenario. This is reflected in the models and design prototypes (as shown in Figure 8) generated for the project.
The gear shapes are reminiscent of the inner working of clocks, car parts, and machines, representing factory production or industry. Further yet, symbolically, the gears represent connectivity and interdependence, since a gear's teeth make it possible for it to connect with other gears in order to form a more complex system. Thus, the fact that in this design the manipulation of one gear affects or changes another constitutes a rather short metaphorical leap—a reasonable mapping to the natural world. Furthermore, in the specific instance of the case study presented by our industry partner—decision making in manufacturing—gears are part of a familiar, if rather dated, visual language. This design leverages what has been recently termed skeuomorphism: where an artefact retains ornamental design cues from structures that were necessary in the original (Basalla, 1989). Adding the soft colour palette to the gears—pinks, yellows, blues, and tans—is meant to suggest a particular type of machine-based production: ice cream flavours. This particular colour choice moves the design away from the harsh contrasts typically associated with metal gears and industrial machinery: greys, blacks, and dark browns. The pastel colour palette has a potential downside, anchoring the design in ice cream production, making it less transferable into other types of manufacturing; however, if the communication goal was to make oil extraction and refinement appear less threatening (softer, friendlier, more people-friendly), then the colour palette may be spot on.
3. Value of Sameness vs. Difference

Manufacturing decisions (particularly, but not exclusively, those within the oil industry) appear to have consequences—both positive and negative—on individuals, communities, and environments. Currently, the oil industry does not consider constraints that have to do with human and environmental factors as part of its decision making process. If it did, we may have to consider graphical representation for non mechanical constraints: individuals, groups, communities, working spaces, and natural and constructed environments and ask ourselves:

- should human / environmental constraints be given the same graphical form as mechanical constraints, such as raw materials, waste, resulting products, and methods of distribution;
- do constraints such as working hours and conditions, sick leave, and safety concerns require a different graphical treatment; and
- should people constraints be treated as visually different from environmental constraints?

If all these constraint types are given the same graphical representation, would the design suggest that people are considered of the same importance as the amount of waste or its disposal? Sameness and difference have many potential interpretations. If all items in a collection are treated the same way graphically, despite any difference in terms of data they may have, they are likely to be seen as equal. Equality may be seen as a positive in contexts where there has been, traditionally, a devaluing of certain categories over others. However, it is also possible that, in the manufacturing sector for example, equality of mechanical, human, and environmental constraints may be seen as a devaluation of the human condition.
In certain cases of graphical representation, each item in a collection needs to have a different appearance in order to differentiate it from the others, but each one is meant to be seen as equal in significance. In figure 10, for example, each ingredient is given its own line and colour. They are meant to be viewed as the same in terms of importance, just unique in terms of type.

If each category of items within a collection is given a perceptually different graphical representation, users would be able to see that the data set consists of, in some way, unique groupings. In certain data visualization, difference may hold more information than sameness, when that difference is, in fact, meaningful. And in certain other data visualizations, difference may, in fact, be critical to its functionality. Consider the Pill Browser, as an example (see Figure 11): it displays the actual photographs of 1000 prescription pills available on the US market. The purpose of this browser is to identify rogue pills by their appearance—imagine you found a loose pill on your Grandpa’s floor and you’re trying to figure out which of his many medications it is. The Pill Browser lets you conduct a visual search based on the shape and colour of the pill. Each pill has to be different in appearance (and in its graphical
representation within the collection) for it to be useful in terms of accurate identification\(^2\).

\[\text{Figure 11: The Pill Browser (Ruecker, Given, Sadler, and Ruskin).}\]

Difference may indicate a hierarchy of importance. If our choice of graphical representation places emphasis on one category of constraints over another, that emphasis will also hold meaning. For example, in the NYTimes visualization *What do you think is the most important problem facing the country today?* colour differentiates category types, and difference in size per category comparatively quantifies concern (the larger the rectangle, the higher the level of concern) (see Figure 12).

\[^2\text{Many pills are, in fact, visually different from each other, and the designers of the Pill Browser leverage that difference in this data display. They also show that many other pills are simply round and white, suggesting that accurate identification may be difficult if not impossible.}\]
**Conclusions & Future Work**

The kinds of graphical representation selected for a data visualization may impact the user’s perception of a category (and the data set it contains), the category’s level of significance and, potentially, the user’s, and in some cases the category member’s, perception of the self. The first part of the preceding statement makes sense to most designers: that the form we assign to an object will impact how that object is interpreted. In data visualization, however, the design challenge can be far more complex: interpretation must often be balanced with functionality. While we can display a thousand dots on the screen, each representing a different item within a collection, our current, common denominator display technology cannot do the same for photographs with enough size and detail for the content of each photograph to become identifiable as a unique item with unique characteristics. This is particularly true if the entire collection is meant to be viewed and browsed as a complete set. This is true in the *U.S. Gun Deaths* and the *Out of Sight, Out of Mind* projects, and the *Mandala* and *Pill* browsers.

Another option is to place the form of representation under the control of the user, so that someone interested in photos could have them represented as thumbnail images, while another user, in the context of a different task, could have them represented by typological categories such as type of camera, time of day, location, subject matter, and so on. Previous studies (e.g.
Giacometti et al., 2009) have suggested that instead of permanently changing representation of the individual items, a preferred strategy is to temporarily change it, then change it back, and use the recently visible information instead as a means of organizing the items. If a user is assigning a graphical representation to her own identity (as is demonstrated through the personalization power of FaceBook, Twitter, and Instagram profiles), she may be empowered by that act; however, if she is assigning a representation to another person or community, such an act may be disempowering or marginalizing.

Finally, since our focus in this paper is on representations of data rather than functions, we are not concerned with buttons, scrollbars, and other navigational objects. However, the distinction between data and functionality is often blurred, both in the case of desktop icons where double-clicking a document will open up the program that is associated with it and, in the case of many data visualizations, where the graphical representation of data becomes an access point for more data. In effect we need to extend our understanding of graphical representation beyond the visual images themselves, into the data, code, or data + code that are connected to the images.

Author Biography

Milena Radzikowska, MDes, PhD
Dr. Milena Radzikowska is an Associate Professor with current research interests in the areas of decision support, feminist HCI, humanities visualization, critical design, and information design. She designs, teaches, and conducts research as a feminist, a committed mentor, and community builder. Her work in human-computer interaction is reciprocally informed by her passion for creating safer, more inclusive and compelling spaces, both digital and analog. Her design and research work is interdisciplinary and collaborative, marked by a passion to work in the service of others.

Over the past 15 years Dr. Radzikowska worked on over a dozen projects designing human-computer interfaces with researchers from the digital humanities, primarily exploring interface design for decision support; visualization for large text collections; online support environments for breast cancer survivors; and wildlife tracking systems for provincial parks. Her work has been iterative and experimental – meant to challenge existing interface design conventions and explore unique alternatives to complex visualization problems. It comes out of the belief that design can and should aim to make a difference to individuals, communities, and society at large. She has co-authored more than 50 publications on data visualization, aesthetics, interaction design, interaction theory, and design for large text collections. She is also the co-author of the book Visual Interface Design for Digital Cultural Heritage: A Guide to Rich-Prospect Browsing.

Stan Ruecker, MDes, PhD
Dr. Stan Ruecker is the Anthony J. Petullo Professor in Design at the University of Illinois. His research is radically interdisciplinary and international in scope. He has been tenured at the University of Alberta, the globally renowned Institute of Design in Chicago, and most recently at the University of Illinois.

Professor Ruecker has co-authored with over 230 different people, working collaboratively in over 20 academic disciplines. His work is broadly in the design of information and communication. More specifically, his research explores the implications of new media on communication and interpretation, including speaking, writing, and experience.

Dr. Ruecker’s research has focused for the past 20 years on the future of reading, producing more than two dozen experimental prototypes. He is currently exploring physical interfaces for complex conceptual work, such as text analysis, modeling time, and designing experience. He is also part of an international group developing new predictive models of key concepts for use by designers. Their current topic is how design can help encourage people to expand from forming opinions to holding multiple interpretations.
As the Anthony J. Petullo Professor in Design, Dr. Ruecker’s focus is on raising the profile of design research at the University of Illinois and expanding the role of design research globally.

Abstract

This paper studies a design workshop that investigates complex collaboration between fundamental physics and design. Our research focuses on how students create original artefacts that bridge the gap between disciplines that have very little in common. Our goal is to study the micro-evolutions of their projects. Elaborating first on Actor Network Theory (Latour, 1996; 2005) we study how students’ projects evolved over time and through a diversity of inputs and media. Throughout this longitudinal study, we use then a semiotic and pragmatic approach to observe three “aesthetical formations”: translation, composition, and stabilization. These formations suggest that the question of material agency developed in the field of archeology and cognitive science (Knappett & Malafouris, 2008) need to be considered in the design field (Renon, 2016) to explain metamorphoses from the brief to the final realizations.

Literature Review

The literature on sciences and design shows numerous collaborative programs (Cross, 1993, 2001 ; Bruffee, 1999; Stahl, 2006; Renon, 2015b, 2016). While interdisciplinarity is advocated by educational institutions and sustained by the analysis of professional design practices (Gentes, 2015) many students who are introduced to design multidisciplinarity are afraid of the vast array of disciplines that they should know and use. The question is how to train for an almost infinite set of knowledges? Is it even possible to do so or is it a myth? And how are students prepared to raise up to the challenge of not understanding the depth of other disciplines that they must work with? Some programs actually engage the students into scientific literacy with the usual argumentation as reported by Feinstein (2011): sciences are helpful even for students who do not intend to engage into a scientific career because they are part of a general education (Donnelly, 2006). Sciences are therefore part of a cultural heritage considered the literacy of contemporary humanists. Science literacy is also supposed to help people make better reasoning and therefore helps them better manage their lives. As far as design education is concerned, Findeli (2001) points out that design has been considered as an applied science. However, he remarks the impossibility of listing the infinite number of sciences that could be applied by design. Yet design also builds a relation to other sciences. In a first fieldwork (2016),
we studied a case of education where disciplines, that at first sight have nothing in common, were brought together. We wanted to better understand how design uses interdisciplinarity in a designerly way to produce new objects (Gentes, 2015, Tovey, 2015). The analysis showed that interdisciplinarity in design can be better understood if one looks at the properties of these situations and how they actively support invention. Five properties that framed the interdisciplinarity of design were discovered and analyzed: affective, cognitive, reflexive learning, economics, and political (Gentes, Renon & Bobroff, 2016). Elaborating on this research, we wanted to further understand interdisciplinarity in practice through the observation of material transformations during the design work. To do so, we used some of the methods and concepts of the Actor Network Theory (ANT) so as to pay special attention to the non-human actors that structure the designers’ work. After presenting how we used the ANT and its methods, we describe the transformations at play through two use cases in detail. The analysis shows three operations that seem to be key to understanding the design practice: translation, composition, and stabilization. We suggest to call these operations: “aesthetic formations” so as to emphasize the aesthetics at play in the design work. In the discussion, we suggest that these “formations” are supported by a theory of material agency (Knappett & Malafouris, 2008; Renon, 2016) that we will try to develop after so and so.

Research Methods

Chain of transformations and Collaborative programs in Design & Science

The Actor-network Theory studies societies as collectives or networks (Latour, 1996; 2005) constituted by human and non-human actors in interaction. This theory takes into account objects and discourses, and the set of relationships and mediations that connects them. These relations are based on a series of translations or chains of transformations, which eventually constitute “the social”. In the same way, the scientific fact is the result of a chain of transformations (instruments, articles, laboratory materials, subsidies, etc.) ANT tends to construe translation as a collaborative performance. Translation, by this account, is a communicative process in which actors inhabiting different social worlds enter into relations with each other, and begin to recast or reconstruct themselves, their interests and their worlds. The sociology of translation “takes the semiotic insight, that of the relationality of entities, the notion that they are produced in relations, and applies this ruthlessly to all materials – and not simply to those that are linguistic” (Law, 1999). Such relationships are not essential or given: they have to be made and maintained, or 'performed'. Law (2009) emphasized the openness, uncertainty and revisability of ANT-inspired Studies. He suggests that we talk of « matériel semiotics » rather than ANT. Elaborating on Law, Yaneva (2015) illustrated the potentials of an Actor-Network Theory (ANT) perspective to design, arguing that design triggers specific ways of enacting the social, understanding design’s investigation as a type of connector, not as a separate cold domain of material relations. Rather than mobilizing the ANT as a strict theoretical framework, we propose, following Law (2009), Fenwick & Edwards (2010), and Fenwick (2011), to take ANT into account both as a tool for reflecting the interactions between humans and nonhumans, understood as spaces of transformation, and to analyze these transformation spaces by re-situating the materiality inherent in any production of design (Danholt, 2012).
Case study: an education program between design and physics

Since 2011, François Azambourg and Julien Bobroff have been organizing workshops called “Design and Research” for students of a school of design in Paris, ENSCI les Ateliers. The workshops investigate forms and materials in a design project. Fifteen to twenty design students at different stages of the design curriculum but with no specific qualification in science have attended these workshops. The workshop lasts four months. In addition to informal interactions, there are generally six formal presentations. The students also have a permanent co-working space to develop their projects. During the workshops, students are given outreach seminars by the physicist together with physics lab visits and open discussions about physics. Students are then asked to conceive a design project inspired by the scientific material. The challenge of the workshop is to work on tangible productions while starting from intangible concepts and notions from fundamental physics. Each year, the designers and the physicist choose a new theme: “Supraconductivity” in 2011, “Quantum physics” in 2013, and “Light and optics” in 2014. Productions are evaluated at the end of the workshop during a collective presentation and exhibition. They are also displayed on websites and further used in various outreach activities: exhibits in science museums, outreach talks, science fairs… In the spring of 2016, the workshop “Design and Research” was sub-titled: “Voir l’ invisible” ("Catching the invisible"). Anne-Lyse Renon made an ethnographic observation during the four month of the workshop (March to June 2016), collecting 12 hours of video, 562 pictures and interviews and informal discussions. Out of the 13 projects done by the students in this session, we selected mainly two (A and B) for this paper so as to give a detailed analysis of productions and discourses. A proposed a game for children and B a pastry cosmology. C is also mentioned who designed a book for children. We chose to focus mainly on students A and B because they presented interesting differences in terms of production (A a tool, B a tangible typology), and were positively evaluated in terms of originality and seriousness of the design work by the designer and the scientist.

Workshops: description of inputs and transformations

Asking design students to work with fundamental physics seems like a particularly tough pedagogical and design challenge. This section looks at how tangible objects were produced while addressing fundamental physics, intangible by essence.

The physicist was the first to suggest a way to solve the paradox. While the subject title could very well be interpreted in mystical terms, the introductory lesson delimited the scope of the project by using a vocabulary coming from physics: “What does « see » mean at the atomic scale? How do we capture and manipulate phenomena at the Nano scale?” He emphasized the scientific standpoint by mentioning:
- human sight as well as the definition of “invisibility”: the definitions were taken from biology and physics;
- tools: microscopes including the history of the instruments;
- recent scientific questions: the limitation of traditional microscopy (Richard Feynman) as well as the technical specificities of contemporary quantum microscopes.

Mostly, his presentation resolved the paradox of “Seeing the Invisible” through a history of
science. However, this resolution was not presented as the only way to address the paradox. The physicist and designers insisted that students would not be evaluated on their expertise in physics, yet they had to produce their own interpretation of what was at stake in the “invisible” within “the specificities of their own materials” (Designer François Azambourg).

The first lesson was followed by a session where students could manipulate scientific tools: magnifying glasses, lenses, mirrors, two or three traditional microscopes, small USB microscopes (which were connected to the computer), polarizers, flashlight, UV lamp and laser (e.g. Figure 1 & 2).

![Image 1](image1.png)

**Figure 1.** The physicist manipulating an optic refraction artefact and doing a demonstration to the student with the designer teacher on his left.

![Image 2](image2.png)

**Figure 2.** Students experimenting the different instruments and optical lenses and microscopes brought by the physicist.

In this propaedeutic stage, students tackled the complexity of the paradox using different
strategies and heterogeneous materials. At first sight, it seems that none of the students were interested by the same things. However, at this stage of “exploration”, we could observe two main postures: either, they isolated and circumscribed an artefact or a theme from the scientific world. Or, an artefact or a theme was the pretext to reach out to other worlds. For instance, student A used the session of manipulation as a stepping stone for her research since it was an occasion to identify tools and functions of microscopy, while student B chose the table of Mendeleev: “guided by the physician, I discovered the Mendeleev periodic table of the elements”. For him, the starting point was more about building a taxonomy of matters than working about an optical phenomenon.

B: "It was from there, on the confusion of the reigns, that I wanted to work, that is to say finally that in the aspect of the table of Mendeleev there is this confusion there since all the atoms create the infinite bodies of materials that are known "

Questioned about their choices, the two students evoked (A) childhood memories of playing with tools and exploring, or (B) their personal attraction for the sensuality and plasticity of matters. The starting point of their design work already put together science and personal experience: A chose a scenario of use where people would manipulate microscopes, and B focused on blending the elements of the classification table.

A: "(...) I went (with a pedagogical association) (...) to La Cité des Sciences (The City of Sciences in Paris), and there I said "yeah, there you really have to do something for children, to play, etc."

Students also tried to find other connections and sources of inspiration through “auto-brainstorming” (student A). For instance, very early on, student B compared the table of Mendeleev to Indian ritualistic objects and this comparison later led him to introduce the notion of “activation”. The first version of his project therefore changed in contact with another network of references. Student A remembered treasure hunts, “hiding things” that she loved doing as a kid. She compared it to more recent experiences with kids at La Cité des Sciences (a place devoted to sciences) and this helped her do her auto-brainstorming. Another student, C, mentioned science-fiction literature that she had read. She also questioned students doing their PhD in Sci-Fi to get more visual and narrative references. This literary design space comforted her into doing a book for children.

This practice of associations is completed by another type of activities that starts from materials and gestures. Student B expressed a pronounced taste for the manipulation of materials. He mentioned that he had a habit of collecting things with which he experimented. Materials were for him at the basis of design experimentations: "To start with, I wanted to invent an elementary paste. So, really from a design point of view, how we could actually recreate an assembly of materials that would be in the form of micro elements ... type of powder, etc. So things one can combine with a more or less equivalent granulometry and which together, depending on the mixtures used, can constitute a number of very different properties ". He investigates even further the principles of combination, by imagining a moving plasticity of materials: "I think my idea was to make something that could be in constant evolution, hence alive. "

A found not only a tool but a good material to investigate: the project “Foldscope”. Designed
by Manu Prakash & Jim Cybulski in 2012, it is an open source microscope made of paper, downloadable in pdf, and hand-assembled with the addition of an optical lens. “I just wanted to see how it works, and understand how to build it.” From there, she began an inquiry about optics and printed images, going successively from digital to analogical production of images in order to find a good way to change the scales of the details she wanted to show (e.g. Figure 3).

![Image](image.png)

Figure 3. Student A handling different type of photographic films, comparing the transparency, the sharpness and the possibility to change the scale.

B wanted to embody complex notions in a device as simple and obvious as possible. But more importantly, he wanted to design for the senses so as to share his interest for physical experience with matter. He finally decided to explore taste because of the subjective and intimate as well as intensely physical experience. He chose food as a fieldwork to investigate: "This was the trigger: I told myself that in fact the food world was very interesting because there is all this faculty of mixing, food, ingredients to create different types of food with different ... tastes, textures. It was hyper global and at the same time hyper simple of apprehension since it was enough to eat it to understand. So it was from there that I said to
myself I will explain chemical links by making people eat them”.

The tangible qualities were essential to build new “versions” (Béjean, Gentes, 2013) to answer the initial paradox. The design work consisted in finding material configurations by comparing properties, testing physical limits, and matching gestures with materials. Materials fought back and stopped the experimentations because of their own properties, their “requiredness” (Rosenthal & Visetti, 1999; Potter, 1980). The designers were surprised by the results that could be different from what they planned.

For example, through his use of materials B wished to change both the relation to a cooking recipe and the symbolic representation of the periodic classification (e.g. Figure 4). However, the implementation of the project was not without certain pitfalls, especially in the assembly of the elements, conditioned by their chemical composition and the properties adjoining their materiality. Hence, B selected 5 substances, which he tried to combine according to an experimental protocol. Since this assembly was not possible from one material to another, the productions finally presented were dictated by the possibilities and the resistances of the material. In the interview, B pointed out the “surprising combinations” of all natural elements and at the same time stressed that the “chemical compositions [of these elements] are much closer than what first appears”.

Figure 4. the student B “pasty cosmology” as it was displayed at the final presentation, the cakes were tasted arranged in the Mendeleev table used as a tray.
For student B, the analogy with cooking goes beyond the mere pretext of production. From a chemical composition at the very beginning, he changes to an aesthetic composition. The potentially infinite process of associations and configurations taking place at different moments was brought to a halt by the necessity of communication of the projects in formal presentations. We observe three stages of successive stabilization in the formation of composition: a first stabilization which is made by the choice of materials and their manipulation. Then from the relation between material properties and manipulation emerges an aesthetic stabilization, linked with the objective of a project rendering and the necessity of doing selections. And finally, the need for circulation leads to a final phase of stabilization which is a communication stabilization.

These presentations forced the students to choose a particular version of their project and to justify their choices. A went straight to a game and emphasized her scenario of use: to provide a microscope that would be a game for kids. The sobriety of manufacture she shaped found its origin in the will of student A to lead the project to an economy of means. The implementation of this playful microscope has thus taken a turn of popularization in the perspective of its concreteness, and the simplicity of its manufacture (e.g. Figure 5).

Conversely, student B proposed to develop a “culinary nomenclature”, in order to explore the complexity of variations and assemblages of edible matter in the manner of atomic transformations (e.g. Figure 6). His quote from Carl Sagan “If you want to make an apple pie from scratch, you must first create the universe.” in some way contributed to the network of associations that creates the “Pastry Cosmology”.

Discussion

From the outset of the workshop, the students took (i) the lack knowledge and (ii) the notion of invisible, as a constraint of production. Two strategies emerged to tackle the paradox of “seeing the invisible”.

Student A wanted to produce a popularization environment. Her idea was to take the scientific technical instrument (the microscope) and to explore the dimension of simulation, hence the tangible tool and the focus on its manipulation. This manipulation is made possible by the DIY construction process, which in turn simulates an appropriation of scientific and technical knowledge.

In the case of student B, the intuitively sought-for analogy between concepts in physics and their modalities of material transcription, proceeds from a symbolization. His work of transfer reveals a relation with the analogy of science to systems (Renon, 2015a; 2016). This "aesthetics of systems" (Burnham & Haacke, 1968), which is dear to conceptual art and to the processes of the "artificial sciences" (Simon, 1969), consists in finding a grammatical or even syntactic relationship between materials in order to construct a universal language close to the periodic table. For student B, understanding the periodic table of Mendeleev relies on an iconic transposition, term by term, or rather terms to materials. And these translation and composition take place through the constraints of the materials themselves, and their specificities, from abstract physics notions to design material production.

However, as we looked at the dynamics of the design workshop, we observed “composites” (Le Marec & Babou, 2003) that included living and non-living actors, symbolic and tangible material, personal memories and inputs from other designers and physicist but also operations of transformation. Elaborating on the concept of composites as heterogeneous semiotic
combinations, we observed how these combinations evolved all along the project but also changed initial meanings by cutting and relating elements in different ways.

**The first “aesthetical formation”** consisted of **translating and networking operations**. Students mixed elements of physics presented at the beginning of the project with personal memories, associating different worlds of references. This propaedeutic moment activated a network of knowledge pre-configuring how they were going to orient themselves. The presentation of the subject was already tacitly a way of setting up chains of transformations towards a project space. However, the translation in this case is not retro-active as in the case of a scientific activity studied in STS. Each “translation” produces a new version and also, as Gentes and Bejean showed in the case of a theater production (Gentes & Bejean, 2012), produces a new definition of the initial paradox. This aesthetical formation is therefore a chain of dynamic configurations where every element influences each other.

**The second type of aesthetical formation** consists in **composing** the "initial paradox" with tangible materials, as well as by gestures and the “manner” of each designer. While these were often chosen brought by the "translating" and "networking" formation, they also had their own logic and resisted the network, surprising their creator. These compositions were evolving because each material resisted, surprised not only by itself but new resistance and new material “behaviours” that appeared when they were brought together. The final video of student C is an illustration of this process of metamorphosis through composition (Figure. 7).
This composing process which can be described as a field of tensions (Gentes 2017) sometimes reached a balance: what we suggest to call a **stabilizing formation**. Things seem to fall into place according to their authors. While most of the literature on design activity focuses on the fixation / defixation issue, we suggest that the design process can also be described as a quest for balance between heterogeneous elements. This balance between elements in tension fixes one version of the design work. Such states of stabilisation are obvious when students need to communicate about their projects during formal presentations. In that particular case, the stabilising formation is directly related to the necessity of social circulation of the project. However, it would be insufficient to attribute this stabilisation formation to the social circulation only. Students, and their supervisors, feel that a certain authenticity is achieved. The videos that give a view of the work process are often a dramaturgy of this goal. The denouement is presented as a refined process of choice, an elimination of useless elements, and an equilibrium reached by the designed artifact.

**Conclusion**

In the framework that we analyzed, designers tapped into their personal history and experience of other projects - in effect introducing even more facts into the project - to create new representations at the crossroads of disciplines but also letting matter speaks for itself in
compositions and eventually stabilized forms ready for circulation. The radicality of the experiment that we presented here lies in the fact that fundamental physics is intangible in essence and the starting point of the design project is therefore abstract. However, the designers took into account and invested the scientific material, which became both a tool and a function for exploration. The word “material” here does not simply point to what is tangible in the productions, nor is defined by a subject / object dichotomy. It is made of iconic, technical and semiotic dimensions, which constitute the “material agency” inherent in any design process. For Malafouris, “while agency and intentionality may not be properties of things, they are not properties of humans either: they are the properties of material engagement, that is, of the grey zone where brain, body and culture conflate” (Knappett & Malafouris, 2008). For us material agency in design is a combination of material engagement as developed by Knappett & Malafouris and the continuous aesthetical dynamic formation process between abstraction, symbolization and shaping process (Renon, 2016). To address the abstraction, it is particularly obvious that the design students constructed their projects between gesture and materiality. By focusing on the students experience, the concept of material agency therefore emerged not only as a grey zone where people and matters are engaged together but also as a "zone" where aesthetic formations take place that are at the heart of the design activity.

Here we can extend the ANT perspective so as to explain the combination of non-knowledge and experience. Even if ANT has been used to explain the design process in recent years, we think that the chains of transformations in the design process cannot be compared strictly to the scientific process. In the ANT perspective, the chains of transformations, from the experiment to the results, are described as fundamentally reversible and reproducible. One can go from the results back to the first observations et redo the experiments under the same conditions of reproducibility. But in a design process, the material agency includes the personal expression that is based in the networking practice of the designer and the resistance of materials while they are composed: shapes and matters talk back. The whole process is eventually not reversible because each “stage” transforms the meaning of the previous “composite” made of operations and matters. We therefore suggested to use the expression “aesthetical formations” so that we could represent the different qualities of these situated practices. First, we could see that they were part of a learning and appropriation process. Formation is here understood as “expansive learning”. The active form of the word “formation” also points to the fact that the design process is potentially an infinite semiotic process. In their evocation of the design process, students deployed an encyclopaedic network of associations. The situations eventually stabilized into certain combinations where they could finally circulate, triggering special emotions and experiences. We also qualified these formation as “aesthetical”. By that we wanted to reassert not only a personal, subjective experience but also as a cultural and historical situation, as well as a social space of communication.

Abstract

This paper expounds the background of Chinese design education as well as the orientation of the design education of Tongji University in the new times, it also collects 458 master thesis of College of Design and Innovation during 2010-2016 as analyzed sample. Based on the coding of subject classification, quantitative analysis and content analysis are made in order to understand the interdisciplinary education status of College of Design and Innovation from the two perspectives: the overall cross-disciplinary performance and the relationship between different cross-disciplinary directions.

Keywords: Design Education, Interdisciplinary, 3D T-shaped, Master Dissertation, Quantitative Analysis, Content Analysis

In the past few centuries, social development has brought a highly refined social division of labor and thousands of occupations, thus affecting the accumulation of human knowledge and promoting the establishment of specialized subject classification in education sector. Each subject is divided into several smaller disciplines, and then subdivided into different professional direction. Of course, there is connection between the various professions, but what the classification tends to emphasize are their independence from each other and the relevance to their corresponding occupations (Gong, 2010). However, the problems we face today are becoming increasingly integrated and complex, and the disciplines highly refined for hundreds of years are gradually showing a new trend of blending with each other either in the design field or in other areas. For design, this "interdisciplinary" trend is particularly evident as it has a mixed lineage of different disciplines from its birth. Many scholars believe that the emergence of interdisciplines is necessary, as Friedman (2012) maintains, “most of today’s design challenges require analytic and synthetic planning skills that can’t be developed through the practice of contemporary design professions alone.” Norman (2010) believes that complex problems involve complex systems and there are no simple solutions to solve them, he also pointed out that the old skills of drawing and sketching, forming and molding must be supplemented by skills in programming, interaction, and human cognition. And Norman himself, is the pioneers who integrates psychology and design into interdisciplinary research. To some extent, "interdisciplinary" design has become one of the necessary means to solve complicated social problems and promote the development of social innovation.
1 The Background of China’s Design Education

Compared to many Western countries, China’s design education started late for many years. During the period of transition from handicraft to industry in China since 50s of last century, the arts and crafts major played the role of China's embryonic form of design education, and it performed more like the visual design based with pattern design and decoration design. As industrial civilization promoted the development of Chinese society rapidly, followed by the arrival of the information age, handicraft culture can no longer adapt to the culture of modern city. In 1998, the name "arts and crafts", after being used for more than half a century, was replaced by "art and design"(also known as "design art") in the subject catalog promulgated by the Chinese Ministry of Education. If the traditional crafts can help people better understand what "arts and crafts" is, then the lower industrial level and social environment at that time did not have much help to make people understand what "design art " is clearly. The definition and boundary of design are still vague and confusing, and many major titles, such as "industrial modeling design" and "environmental art design", still seems closely related to art and shape.

And even more irony is that the graduation of design art is awarded with a literary degree. Since the beginning of the 1980s to this century, China has entered a period of rapid economic growth and the demand for design professionals increased dramatically, which has stimulated the large-scale development of design education as well. Some design schools are still focused on teaching design skills or methods of certain aspects (Gong, 2010), while several first-class design schools have a more open and inclusive understanding of design, and began to go with the tide of world development. In 2011, the Chinese Ministry of Education took “art” out from the literary category to make it as the 13th independent subject category, with “design” as one of its five first-level disciplines for the first time. And under the discipline, design is also subdivided into different majors, such as industrial design, visual communication design, environmental design and so on. At present, the rapid development of Internet technology has brought a new round of social change, with new business models, ways of thinking, and social relationships, as well as increasingly complex social problems and needs. These changes have posed new challenges to design field and have spawned a series of emerging design areas that are mostly interdisciplinary and innovative, such as interactive design and service design. As many western countries did, some design schools in China have gradually established interdisciplinary laboratories and incorporated these new crossings into their discipline systems.

In this sense, in China's design field and design education, the boundary of design has gone through such a process: from simple to fuzzy, from fuzzy to gradually clear, and then to the integration and expansion.

2 A 3D “T-shaped” Design Education Framework

The object, environment and requirements of design are becoming increasingly complex, which brought the design field with a series of new challenges. In this context, College of Design and Innovation (D &I) was established in May 2009 as one of the independent colleges of Tongji University, and before that it was only a part of the College of Architecture
and Urban Planning. On the basis of the discussion of "T-type talents" with both vertical and horizontal abilities at the same time, D&I has put forward a 3D T-shaped educational framework based on the prevailing Undergraduate-Master-PhD system: Undergraduate education focuses on vertical capability, aiming to educate design professionals who have innovative thinking and broad knowledge; Master education focuses though on moving beyond vertical capability toward horizontal development, emphasizing fostering learning experience of interdisciplinary knowledge, integration of innovation, design methods and international practice; PhD education emphasizes the depth of knowledge and theories (Lou & Ma, 2014) (See Figure 1). According to Lou, this orientation on the one hand is derived from the teaching tradition of Bauhaus, on the other hand, is related with the current undergraduate education conditions in China (Fang & Wang, 2015).

![Figure 1: A 3D “T-shaped" innovative design education framework (Lou & Ma, 2015)](image)

It is easy to understand that the emphasis on cultivating vertical capability in undergraduate education is largely based on the consideration of the existing social needs, while the emphasis on cultivating horizontal capability in master education is a positive response to the interdisciplinary trend. In order to meet this training goal, D&I canceled the classification of departments in its policy and teaching system, that is, to create a "program" system to organize different majors. (Fang & Wang, 2015). All the students are distributed into 3 vertical programs (industrial design, environmental design, media and communication design) and 4 horizontal programs (interactive design, product service system design, design strategy management, design history and theory) according to their choices. In addition to taking the required courses included in one’s own program, he can also choose courses or projects in other programs freely and get the credits, which breaks the obstacle of interdisciplinary between different departments. In addition, two practical projects, collaborative design and collaborative innovation, are set in the master's teaching modules respectively in the second and third semester, which promotes the master students to deal with complicated design issues through the communication and cooperation with students of different majors.
D&I came into being in the transition era of design, and its reform was carried out step by step during the process of exploring development and teaching practice. Reconsider this process, we would like to ask: How much does the idea of fostering interdisciplinary knowledge and integration of innovation impacts the students? And What is the actual performance of the students in the interdisciplinary design and research? As we know, the master students receive professional education and engage in academic research in the college, their thesis can reflect their status of design and research intuitively, which means the dissertation could be an important medium for us to get the answer.

3 Research Designing

3.1 Data sources and methods

The master dissertation data of graduates for this paper is derived from the Degree List of Tongji University (Degree management office, 2016), and the sample collected starts from 2010 because the D&I awarded its first batch of master's degree in this year. Finally, 458 title lists of master dissertation of D&I from 2010 to 2016 are collected in total, each containing the author's name, degree award Year and thesis title. Based on this sample, this paper is going to make a research by quantitative analysis and content analysis (Qiu & Zhou, 2004) among all these title lists, and to give a description and brief review.

3.2 Data processing and research steps

In the data processing stage, this first step is to use the Excel software to quantitatively analyze the year of the degree awarded and dissertation quantity correspondingly, and then describes the general situation of the master's degree granted in the College. In the second step, the coding table of disciplines/majors is compiled according to the title lists of all the dissertations. The third step is to manually analyze the subject content of each dissertation and code it with its involved disciplines/majors tags. When it comes to the one that is difficult to judge, keywords, abstract and the full text of the dissertation will be used to help make an identification.

3.3 Coding process

As the research range in design field is broad and blurry, and the academic framework has not established yet, there is no clear classification of disciplines that can be applied directly. This paper is to explore the interdisciplinary trend on the basis of the existing disciplines. To ensure a targeted research, the classification of discipline was based on the combination of the 7 programs of D&I, the "six in one" design arts disciplines system described in the article Design Objectives and Scope of Design Art Studies by Li (2003) as well as the the actual topics presented in the sample. As a result, the10 design disciplines tags were identified to cover all the major design categories contained in the sample: 01 industrial design, 02 environmental design, 03 media and communication design, 04 interactive design, 05 product service system design, 06 design strategy and management, 07 design history and theory, 08 craft design, 09
experience design, 10 system design. It is worth noting that "04", "05", "06" and "07" are the D&I's horizontal "program", which themselves were developed by the cross-disciplinary, but what will be discussed later in this paper is the re-cross and re-integration based on regarding them as separate independent disciplines or majors.

For the main non-design disciplines involved in the sample, this paper referred to the classification of "related disciplines" by Li (2003) and the existing disciplines in the field of natural sciences and humanities, and identified which has been a lot of non-design disciplines categories: computer science, materials science, psychology, culture, economics, marketing, behavioral science and so on.

Coding the title lists is the core of this research. According to the coding tags formed above, all the master dissertations in the sample will be classified into the 10 design disciplines and the corresponding non-design disciplines. The classification criteria described in Object and Scope of Design Art Studies is the main standard of coding. However, the boundaries of each discipline are not very clear actually, so the coding process needs always follow the principle of "closely linked to subject, highly summarized, with no one missing" (Yan& Zhang, 2015).

4 Analysis of the Sample

4.1 The overall situation of the dissertations
In general, the number of dissertations is basically stable at 60-70 per year, while in 2013 there was a small peak, mainly because there were 17 double master's degree students coming from the other countries who were awarded a master degree in this year and it is generally at 6-12 or less in other years (See Table 1).

</tbody>
</table>

4.2 The distribution of disciplines and the interdisciplinary trends
It can be observed that the main research contents of many master dissertations involve different disciplinary dimensions, including the cross of the directions related to design and the cross between the design disciplines and the non-design subjects.
Just look at the distribution of 10 design disciplines/majors, the dissertations involved in all directions is not uniform. As shown in Figure 2, environmental design, industrial design and product and service system design are the most concentrated directions, especially environmental design with 144 dissertations related to it, and the number of industrial design direction is 86. Although the product service system design has been frequently mentioned in China only in recent years, the master dissertations in D&I has been a large number, up to 94.

In general, most of the dissertations focus on one discipline or direction. But in the total 458 master dissertations, there are still 183 significant interdisciplinary performances, and the proportion is over 40%. Among them, a large part (92.3%) of the interdisciplinary dissertations mainly involves the research of two disciplines, and there are still a few involving 3 to 4 subjects. (See Table 2).

4.3 Multi-dimensional association between disciplines

As the majority of the interdisciplinary dissertations are those involve two disciplines or majors (92.3%), and it is more convenient for us to observe the relationship between two variables, this paper in the following will deal with this part of data to make a statistical analysis in order to find out more rules in the association between different disciplines.

This paper grouped the statistics of dissertations involving two disciplines and then got the correspondence between various disciplines (See Figure 3). The figures in the cells of Figure 3 represent the number of dissertations involving the two disciplines that correspond to that correspond to the horizontal and vertical directions. From the total quantity of cross-disciplinary dissertations, the discipline which has the largest number is environmental design, followed by industrial design, design strategy and management, media and communication design, which reflects to a certain extent that the vertical discipline such as industrial design, environmental design and visual communication design, shows a greater potential in combination with other new disciplines compared to the horizontal cross-disciplines. In addition, there are also 62 dissertations related to both design and non-design disciplines, indicating that the cross between design disciplines and non-design disciplines is also significant. The following will be the specific analysis of the interdisciplinary association.

4.4 Interdisciplinary research within design disciplines

Most of the main disciplines and directions involved in the master dissertations are in the range of design disciplines, which perform as the communication, infiltration and interaction between various design disciplines.

In Figure 3, the interaction between environmental design and other disciplines is the most frequent. From the perspective of its cross-correlation, the integration of environmental design with system design as well as experience design is relatively frequent, followed by media and communication design, design strategy and management, service system design. Observing the specific dissertation titles, the integration of environmental design and system design is mainly based on the design for residential space, exhibition space, farm community, subway transfer space and other space. As it shows in Table 3, the systematic design focuses more in global organization and overall optimization compared with the layout planning and decoration design in the traditional environmental design. In addition, the combination of environmental design and experience design mainly focus on the design of commercial space, learning space and display space, while the integration of environmental design with media and communication design is manifested in the visual image design, information system design and guidance system design of a certain space. The expression in the design of the guidance system often needs the elements and tools of media to help convey its idea, but guidance system design requires a stronger spatial cognitive function compared to media and communication design alone (See Table 4).

What’s more, the interdisciplinary characteristics of industrial design is relatively clear as Figure 3 shows. In many design disciplines or majors, the association of industrial design and design strategy and management is the most obvious, including strategies research on competition for students and industry design enterprises, and the improvement of brand image or exploration of design management for the industrial design-related Enterprise ,as well as process research of specific product design (See Table 5).

Except for environmental design and industrial design, the interdisciplinary design is relatively frequent between design strategy and management with media and communication design. For example, "brand design" is usually locate the brand image through strategic method, and express the brand concept effectively by the means of media and communication design. Media and communication design and interactive design also have a lot of integration, such as “game design”, its presentation is often inseparable from the collaboration of both visual communication design and interactive design; In addition, "interface design" often appears in industrial products, tending to make an interactive interface for the product, and it is usually combined with the media and visual communication design as the graphic design knowledge often plays a fundamental role in this process.

4.5 Cross research between design disciplines and non-design disciplines

As we can see from Figure 3, the design disciplines do not only make an internal integration with the other design related disciplines, but also collide with some non-design disciplines to form new research directions.

All non-design disciplines included in the samples cover a wide range of disciplines, exceeding 30 categories. Among them, psychology and materials science appears the most frequently, followed by behavioral science and culture. Computer science also appears, especially in the application research of the current cutting-edge technology such as virtual reality and augmented reality. Some disciplines appear few times in the sample, but are quite characteristic, such as information visualization, network engineering, mathematics, perceptual engineering, physical education are such related non-design disciplines and so on (See Table 6).

</table>

In the direction of the 10 design disciplines, industrial design integrates with non-design disciplines most actively, with 20 dissertations in the sample. Among them, the combination of industrial design and psychology has a high quotient of the master dissertations. For example, the dissertation Analysis of the influence of the design of the lighting products on the user's emotion written by Liang Guopeng and Research on the approaches of emotional design for Chinese kitchenware written by Li Bo are typical case of emotional design which explores how to take the user's psychological needs as starting point to improve the emotional effect of the product design. Moreover, material science is also a major discipline that industrial design combined with. Interestingly, the three dissertations which shows such a combination in the sample all have discussed the application of bamboo material in product design, it might because bamboo itself has excellent nature characteristics and Chinese have a deep affection for it. In addition, behavioral science and culture are also the non-design disciplines that combined with industrial design frequently (See Table 7).

Environmental design also has been combined with non-design disciplines a lot in researches. Some of them discuss how materials can be used in environmental design, some of them explore how to incorporate culture or bionics into space design. In addition, the combination of agronomy and environmental design is also typical in research, which is mainly based on the introduction of the topics "family farm" in recent years, it has also formed a new area gradually for the cross research in environmental design field.

Besides, there are many cross-research examples between interactive design and some other non-design disciplines, such as the design research of children's educational games on mobile terminal based on the collaboration of pedagogy and interactive design, as well as the dissertation Research and application of augmented reality technology in the APP Design of Mobile Terminal written by Cui Xiaochen in 2016, which combines both computer science and interactive design to follow the research boom of AR in the current technology industry. In addition, Media and communication design is often combined with the specific branches of culture, trying to seek inspiration for graphic design from certain cultural elements.

5 Conclusion

In the past seven years, D&I in Tongji University has formed a philosophy of expanding the students’ capability from horizontal to vertical through the educational practice, just as the formulation in its 3D “T-shaped” Design Education Framework, learning interdisciplinary knowledge, integration of innovation and design methods are emphasized in the master education. The topics of years of master dissertations in D&I actually reflects a great degree of "interdisciplinary" performance as a result. Among them, the cross-integration within the design disciplines takes over the dominant position, and the communication between the design disciplines and the non-design discipline is also reflected in numbers of master dissertations, especially the integration between industrial design and environmental design with psychology, materials science, behavior science and some other relevant disciplines.

As an applied discipline, the design is responsible for solving the practical problems of the society, so that to adapt design education to the practical social needs is particularly significant. Interdisciplinary education is not a denial or subversion of the classification of traditional disciplines, but should be understood as the way to form a new academic point of view, methods and cognitive through the interaction and integration between multiple disciplines (Tang, 2014), its core lies in enhancing diversity of research organizations and disciplines structures, thereby enlisting the subject and promoting innovation to address the increasingly complex social problems. In the specific design education practice, it is important to implant the sense of jumping out of circle into the students’ mind, so as to make the interdisciplinary idea become their conscious behavior in order to cultivate a group of qualified innovative and compound design professionals.

Author Biography

Lisha Ren

Lisha Ren was awarded her doctorate in architectural history and management by Tongji University in 2010, and she has been a visiting scholar at University IUAV of Venice, Venice International University and Lehigh University. She is currently working as the associate professor and master tutor in College of Design and Innovation, Tongji University. The main research directions of Ren include design history and theory, bridge aesthetics and bridge landscape, and she has published a number of professional papers at international conferences such as IASDR, DRS, CUMULUS.

Yan Wang

Yan Wang is currently studying for her master degree in College of Design and Innovation, Tongji University. She has communicated in the Italy design summer school organized by the University of Bologna in 2016, and have also studied in University of Art and Design Offenbach in Germany as an exchange student.
How to Teach Industrial Design? : A Case Study of College Education for Design Beginners

Joomyung Rhi, Yonsei University, Wonju, Korea(South), jmrhi@yonsei.ac.kr

Abstract

Industrial design education has existed for a long time as part of the university system, but the curriculum and contents of each subject vary considerably from school to school. In recent years, the introduction of new concepts that change the definition of design has blurred the boundaries of design, making the curriculum different. Establishing a standard curriculum to address these challenges is an important task, but it is necessary to fully understand how design education actually takes place and to share content with educators. This paper aims to contribute to the debate on industrial design education by fully disclosing the process and results of the first stage of industrial design education of a university by autobiographical method. The first course, Product Design Practice 1, is a studio class based on a task feedback iteration system. Students are required to submit assignments showing weekly progress. The instructor reviewed the assignments submitted before the class and gave written comments in class. In addition, details of the design process and method that are difficult to identify as novice students are learned through twelve case studies and applied to the project. This Task Feedback Repeating Class system gives students the opportunity to implement design ability while gaining detailed skills with a comprehensive view. Through this process, the researcher got a reflection on the class and implications for the improvement of the class.

industrial design; design education; task-feedback recurring system

Unlike secondary education, university education is very autonomous, which is operated according to the intentions and abilities of the instructor. The academic department of universities seeks to build formal curricula and educational content that shares common values through explicit and tacit agreement between academics and researchers in academia. However, in disciplines where the system of research has not been established yet, the autonomy of the instructors may increase and the variance between schools also does. In this case, sharing examples of individual pedagogical methods has a positive impact on knowledge formation in the field.

Study Goal and Methodology

In the past, the curriculum of industrial design that planned form elements of mass-produced products aimed at fostering stylists with expression-centered education. In recent years, the industrial design curriculum has been changed to train strategists who develop concepts and strategies for new products through creative thinking-oriented education. (Bu,
S., 1994, pp. 12-25). The progress of this phenomenon differs from country to country. (Lee, S., 1998, pp.19-20) Despite the slow changes in the curriculum, Korea has already begun to blur the boundaries of the design field. (Rhi, J., 2007, pp.85-87) With the decline of traditional manufacturing industries and the emergence of intangible interaction and service design, the scope of objects of industrial design is expanding. As industrial design curriculum blends existing contents with new ones, industrial design is becoming increasingly confused with identity. The emergence of the term 'design thinking' that seems familiar but still unfamiliar is contributing to this confusion. It is time to discuss the future of industrial design education and establish common goals based on current education situation.

Many studies on design education are about proposing and analyzing advanced curriculum (In, C. 2009, Jung Y. 2011, Kim, H. 2011, Kim, G. 2011, Chung, W. 2012, Shin, H. 2012, Lee, J. 2013 and Lee, S. 2013). Few studies have shown the actual operation and training results of existing curricula. The purpose of this study is to elaborate the individual instructional structure of industrial design majors and describe in detail how students respond to given steps and guidelines. This is a form of autobiographical research, and follows four stages of the Currere method consisting of a degenerative, progressive, analytical, and synthetic step. This type of research allows researchers to have a positive reflection on themselves and can provide insights and suggestions for future classes to instructors in the same field.

**Characteristics of Design Education: Studio Lessons**

The objectivist epistemology that knowledge exists objectively regardless of human will is replaced by constructivism in which individual experience constitutes knowledge and meaning. This change in paradigm places emphasis on the will of the learner in education. It is recognized as a teacher's role to create a place where learners can think for themselves, rather than one-sided knowledge transfer to learners because it is universally agreed that learners constitute their own knowledge. In other words, learning is a process of actively constructing meanings based on subjective experiences and social interaction of learners in a given situation and context. In particular, it is a common practice for a college or university to teach design courses in a studio style that encourages learner self-reflective thinking and creative problem solving.

This seems to be similar to the traditional apprenticeship method, in which the teacher sets an example and the student imitates and follows it to acquire the master's expertise. However, apprenticeship training is an inevitable education method for the transfer of tacit knowledge, while the studio teaching of industrial design differs from that of apprenticeship education by the nature of knowledge to be delivered and the way of obtaining, accumulating, transmitting, and reproducing knowledge. As IDEO Tom Kelly mentioned, industrial designers are not experts in all areas of the project and are experts on how to solve problems. (Kelley’s interview, 1993.7.13.).

The knowledge required to carry out projects in the field of industrial design cannot be summed up in one or two textbooks. It requires wide range of knowledge in various fields
such as society, culture, economy, management, production. In addition, emerging new technology and the new trends in information use require learner's constant access to relevant knowledge. Furthermore, the knowledge and information they need is literally new, whenever they begin a project with a new context. Therefore, students need to learn how to get knowledge and information and build meaningful frameworks rather than being given piecemeal knowledge and information. The constructivist thinking mentioned above constitutes the background of this educational approach. Lee suggested that the following five factors are necessary for conducting the studio lesson. (Lee, D. 2008, p.150)

(1) Self-directed learning about learning objectives, contents, method and evaluation. Active problem solvers with voluntary control
(2) Context-based learning environment
(3) Improvement of design expertise through exchange, dialogue, and cooperative learning using various human resources rather than personal ability.
(4) Self-reflective learning environment. The opportunity to reflect on himself/herself
(5) Transforming the role of the instructor into a student's coach, mentor, information provider, and senior expert rather than a one-sided knowledge transferor.

**Industrial design education system of ‘A’ university**

‘A’ university in Korea consists many academic departments including science, engineering, management, social sciences, liberal arts, and design courses. Design course of the university selects 50% of new students by reflecting mainly the result of the art practical skill test at entrance examination, and the remaining 50% is selected by the results of GPA and Korean SAT. The first year students are required to select five subjects from these basic courses such as basic design, digital expression, drawing, expression technique, digital modeling, coloring, design and idea, human and design, science and design. When they start second year, students have to choose one major from three different majors including industrial design. The curriculum of the industrial design major consists of a total of 60 credits, and the number of courses is total 19, which is 3 ~ 4 courses per semester. In order to deepen the comprehensive abilities of design, most of main courses such as product design studio 1, product design studio 2, system design studio, emotion design, interaction design, interdisciplinary research and graduation research are conducted through studio project. The remaining elective courses provide students with the necessary knowledge and skill to help them succeed in the above studio courses. The lower grades are generally related to basic knowledge and skill acquisition. As students move up to the upper grades, they can view the outline of industrial design from an expanded perspective and participates in various courses to help them adapt to society after graduation. All subjects are linked to a prerequisite system to form the entire curriculum.
The core of the first semester of the second year is Product Design Studio 1, which runs concurrently with other courses such as CAPD, Cognition and Design, and Gestalt Construction Studio. Other classes unintentionally support the work of students in Product Design Studio 1. Because students use knowledge and skills learned from other courses to create their works of Product Design Studio 1 class. CAPD (Computer Aided Product Design) is a course for students' ability development for 3D modeling. They can learn the basics of NURBS modeling and practice the techniques of the Alias and Rhinoceros programs. The cognitive and design class is a theoretical subject that learns human characteristics, including cognitive ability. Based on this class, they study the ergonomics course to be opened in the next semester. Compared to the product design process dealing with real products, Form Practice Studio naturally learns Gestalt principles and creative attitudes by handling relatively light topics. Students are usually complete 3 to 4 courses(9 to 12 credits) from their major out of a total of 6 to 7 courses(18 to 21 credits) in a semester, because it is not easy to deal with many design subjects at the same time. Sometimes, students do graphic design, business administration and etc. as their minor courses.

Outline of Product Design Studio 1

As the first core class of industrial design, Product Design Studio 1 has the following instructional goals.

① To understand basic concepts of industrial design: Students understand the definition of industrial design that is responsible for the emotional realm of the artifact world. Students will understand the scope and content of industrial design through an overview of the world and an understanding of the areas of design including industrial design and its subdivisions.
② To understand the principles, processes, methods, terms and significance of industrial design: Students will understand the basic principles of industrial design to extract and combine the conditions that objects must meet. Students understand design process and also acquire a number of related terms.

③ To learn how to create concepts: Students understand the process of how the industrial design forms a new concept. Students will be able to combine creative thinking, logical thinking, and data-seeking skills and make presentations that convey them and increase their persuasiveness.

④ To understand significance and method of sketch: Students understand the significance of a sketch, a circulating tool of thought that visualizes ideas and triggers thinking again. In addition, students are taught the three principles of accurate, structured, and inquisitive industrial design sketches to utilize such sketches as a tool.

⑤ To understand the significance and method of model making: Students understand the significance of prototyping, a key method of design thinking as well as concept formation. Students have the ability to create models in three-dimensional sketches. Especially, they use soft model as an appropriate material to make quick circulation tool of thought.

⑥ To improve capability of related software operation: Students develop the ability to use a variety of related software in view of the growing importance of digital simulations.

Classes consist of four hours of common time that is conducted by the instructor and two hours of practical training guided by teaching assistant to expand sketch capacity. Four hours of common time consist of case discussions, lectures based on submitted tasks and weekly instructional goals, individual task guidance, and other progress explanations. At the beginning of each week, instructor delivers 1 to 3 sheets of weekly 'Lesson Points' that contain comments based on the tasks submitted by the week. Table 1 shows the 4-hour common time plan that was presented at the top of each weekly handout. Actual time management may be somewhat different, but it has been generally followed as planned. Critique used to need time more than planned, because individual task guidance for more than 30 students takes quite a long time.

Therefore, there were many cases in which the students used the additional time after the class or the individual instruction was performed in the corner of the classroom for 2 hours during the sketch class. The sketch exercises were conducted only for the students who need more practice. The mandatory participants for the training were selected from a sketch test held in the first week.

The process of completing two projects for each of the eight weeks in a total of 16 weeks is the most important component of this course. Project 1 (hereafter referred to as "P1") is a project in which team members work together to develop knowledge and skills through teamwork.

Project 2 (hereinafter referred to as "P2") was intended to provide individuals with independent design skills, with a focus on enhancing the individual's overall ability to be missed easily during team work.

The subject of P1 is 'container of simple form' and it is created through a process that consists of idea, sketch, model, and presentation panel, evaluation. The reason for choosing such subject for the first project was to take into account the simplicity of production, structure, the material, and the function so that students could grasp the whole process within a set time and fully handle the object to experience completion. By completing P1's tasks, students gain confidence that they will be able to proceed with the project as well as the ability to proceed with the rudiments, thereby enabling them to play a role as a preparatory course for the full-fledged process P2.

P2's subject was 'headgear for various purposes'. The theme 'headgear' was a generic term for wearing on the head. It was a comprehensive naming so that students could try various things while considering the human element of the head. Subject 'Headgear' is similar to P1's 'Container', but it is a more complex task than a container because the human element of the head is deeply involved. The process is almost similar to P1's, but a research phase for the user and basic usability has been added. In order to make sure that the human element is more accurately reflected in the result, they were required to test of fitting with the head of several colleagues in the middle of process, and to present it wearing a helmet mock-up on their head at the final presentation. Through this process, students were able to find logical ways to satisfy many human dimensions.

**Core elements of the course**

**Class points, weekly assignments and individual guidance**

During the 16-week period, students need to do a weekly assignment. Students uploaded the assignment to the official university's internet storage two days earlier of the class day and shared the contents of the assignment with each other. Instructor prepared the Lesson Points that contains the comment about the assignment submitted for this week and students' progress shown, and uses it to lead the class. Also it provides guidance on individual tasks to students.

Individual instruction to task were not only for the individual but for all students in the class to learn from the comments for colleagues. These kind of sharing knowledge in the
classroom is quite efficient to convey many things within a short period of time. Thus, comments on individual assignments were shared by all students so that they could learn common lessons. (All material is kept on the storage for 2-3 weeks.) Instructors' comments lead to students' questions, responses and discussions. The content of the comments took the form of encouraging best practices rather than pointing out the wrong parts. Various kinds of praise communication were made, such as adding G (good), VG (very good), EX (excellent) to the assignment file name as an indication of encouragement. The Lesson Points also contained a note in the form of a key word and a question, which enabled the student to identify key points by color, letter size, and underline.

Lecture and sketch practices

The lecture focused on the core theory of industrial design, which is a core curriculum. The instructor delivers the same sub-message several times over several weeks until the students are fully aware of the content. Instructor used carefully selected case studies to illustrate the theory to make it easy to understand. (See Table 3)

After the class, in the afternoon, 2 hours of hands-on teaching experience was taught by a teaching assistant. Students who have difficulty sketching are designated to attend, and unspecified students are allowed to participate if they wish. In general, about 4/5 of the students were assigned in the beginning, and about half of the students participated in the end of the term. Sketching exercises mainly focused on line drawing exercises, ellipse drawing exercises, perspective, shadow and contrast, and layout techniques. However, it was more important to understand and practice the three principles of the industrial design sketch that the instructor set up empirically, namely 'principle based sketch', 'structural sketch', and 'inquisitive sketch'. ‘Principle based sketch' means a sketch that understands and applies the visual expression principle such as perspective and projection. ‘Structural sketch' refers to a sketch of three-dimensional expressions with the invisible back side of things or phenomena to be described. It is important to draw on the three-dimensional structure even in the two-dimensional representation, because industrial design differs from the two-dimensional expressive sketch in the field of graphic design, as it depicts the structure and state of an object or phenomenon. The 'inquisitive sketch' is not a picture to show a shape on a piece of paper, but a sketch in which the trajectory of one's own idea is revealed naturally. Such a principle is not necessary for sketches to be a simple image depiction but rather as a medium to record the flow of thoughts and generate new ideas from it. The exercises were checked through a short test with emphasis on speed, and the overall progress was confirmed through a sketch test on the midterm exam.

10 weeks of case study presentations and discussions

A case study is a very useful way in which students can extract suggestions to look at their work from an already conducted case. A total of 10 cases were reviewed during the period from 3 to 7 weeks to 9 to 13 weeks. The case used a well-organized case in the "Design Secrets" series, which was designed and published by IDSA. Despite the advantages of students finding cases on their own, the intention was to save time on the case search process. The weekly allocation of the cases was structured so that similar examples could be examined according to the progress of the project (1. vessel, 2. helmet). The students read about 4 pages of the English version of the case that was assigned to the team and shared the key contents and implications in the class. Given the limited data available, recent cases, or recent activity of the company, and related product lineup have been reviewed to add depth to the case to complement the current view.

The case study session lasted about one hour per week. First, when the presentation team explained the results of the case study for about 15 ~ 20 minutes, three designated questioners first raised questions, and after the discussions came, naturally, all the participants participated in the discussions. But the discussions were not easy and needed a lot of encouragement. Therefore, the question group was appointed weekly separately from the presentation team, and the group was encouraged to discuss the case with the presentation team by reviewing the case in advance and raising further questions or discussions. At the end of each weekly case study session, the instructor will arrange the relevant key content. After the class, the students posted three new words and testimonials on the online class bulletin board. In addition, the contents of the case were presented in the regular examination so that students could concentrate more on participating in the
discussion. The team that published the case summarized the contents of the presentation and the discussion on the day, and submitted a comprehensive report on the case at the end of the semester.

Testing and evaluation

Submitting a weekly assignment and reviewing it is a great help in understanding the progress of students and preparing for the lesson. Therefore, submitting the assignment in good faith is very important for maintaining the education system, so the submission is counted in the student's credit calculation. However, the contents of the assignments may vary widely depending on the characteristics of individual students and individual subjects, and the quantitative evaluation was not carried out because untimely assessments may undermine their characteristics. Only qualitative and integrated comments on the assignment were continuously given and shared so that all members of the class could refer to it. This feature of the weekly evaluation of the task was guided to the students at the beginning of the class so that the students could judge the value of the task contents themselves.

The final results of the two projects were evaluated. At the end of each project, the results were presented through panels and models, and presentations were held in the classroom or in the exhibition hall while other professors attended. In Project 2, which has the subject of a headgear that could be used on the head, students were asked to wear a headgear of their own to prove that they had properly checked the physical use of the person.

Even though this class is a studio-based class, midterm and final exams were held. The midterm exam was a written test including a sketch exam, and it was mainly aimed at confirming the contents related to the product development that was found in the case study. The results of the sketch test were also used to identify those who would continue to participate in the additional 2-hour sketch class. The final written examination required understanding of the core issues revealed in the case study after the midterm exam and describing the detail of their design process so that they could reflect and establish their own method.

Discussion

Product Design Practice 1 consists of 15 weeks of continuous interaction between sharing and teaching through weekly classes and students' assignments. Weekly assignments (projects, examples, etc.) were a good way to see students' understanding and progress. Through it, the instructor reconfigured the weekly schedule by supplementing the original plan. The students were able to participate in the class after they had compared each other by preliminarily reviewing previously submitted assignments on the web. The project serves as an important device for synthesizing individual exercises. Project 1 of the preliminary nature also provides the framework and skills training opportunities needed for Project 2. In addition, midterm and final exams are conducted to evaluate the degree of theoretical learning and sketching abilities. At the end of the semester, the final goal of presentation and exhibition is presented, inspiring students' enthusiasm. All elements of this class, ie, tasks, comments, projects, tests, presentations and exhibitions, are linked
together to form a structure that promotes student development. This structure is referred to as the task-feedback recurring system.

Figure 2: Task-Feedback Recurring System

At the end of the semester, a review process was conducted to see what ideas students had as a result of the lessons. Two questions were asked. The first question was asking what is the most important design ability for designers. Students wrote two items that they thought were important. They emphasized the importance of expressive power and the need to grasp what people want. Particularly, students thought that it was important to draw out user research questions, to observe and write notes, to observe, and to record using mobile phones. Sensitivity, creativity, user understanding and consideration, and the importance of repetitive attempts are also presented by a few students. It can be explained that students have a general understanding of the core concepts of industrial design, principles, and concept formation, which are the objectives of Product Design Studio 1.

The next question was a more comprehensive question: what are the characteristics of a desirable design, and how do you think about design? The students described the answer more narratively than the previous question. From the concept of design to the ability of design, to the conditions of the design outcome, opinions came out, and the level of opinion was very high compared to the learning period of only 3 months.

</table>

A: Every design is the result of a big goal backed by a lot of small ideas.

B: The designer's capacity is to recognize the need for new design in his life and design it for many people.

C: When I was a very young boy, I remember that my grandfather made a basketball hoop for me in his handmade yard. Could design for one person be the most beautiful design in the world?

D: I think that the design for each person's personality will make the design more enriched. No one wears Haute Couture's clothes in everyday life. But the clothes make it feel more fashionable and richer. "

As mentioned earlier, the class of industrial design has a constructivism characteristic. But it would be more appropriate to describe it as training in a more comprehensive thought process than in traditional apprenticeship training. In addition, this class was operated in a more tightly structured way, with the aim of developing autonomous reflective thinking. According to a constructivist in education field, the learner needs self-directed learning, situational contextual learning, self-reflective learning and cooperative learning, and the instructor needs to function as a learning facilitator.

One of the characteristics of this class is that all the schedules are planned and tightly organized. In the process of solving the tense design problem, the student develops the basic ability of the individual to understand and synthesize the characteristics of the design.
object. In other words, it was a process of training that gave the students the skills and attitudes necessary to carry on their own tasks. However, students are likely to feel fatigue in such a process, and are likely to become somewhat inadequate in their self-initiated aspects. Some students commented on the situation as follows. "I did not know that the semester would go on without such a break." “I could not afford to read other books.” Providing students with a loose course gives them a chance to contemplate their work, which can be a good strategy for students to lead their own reflection. There is still uncertainty as to which of the basic intensive training and reflection times is more appropriate. It seems to be a task to examine through more empirical research in the future.

**Conclusion**

This paper intends to reveal a scene of the first stage of industrial design class at university level. College classes should reflect dynamic research results in the field, and design education, in particular, places importance on embodying rather than simply retaining knowledge. Especially, it is not appropriate to transmit fixed contents depending on textbooks because it requires the embodiment of methods separately from the embodied knowledge. Therefore, rather than adopting a single exemplary design knowledge delivery system, it is highly necessary for all schools to demonstrate and share various examples of design teaching methods according to individual needs and to improve them in a reflective manner. For this purpose, this paper analyzed the structure and content of 'Product Design Practice I' which is the first major course of Industrial Design Department of University A.

This course is based on studio lessons focusing on two projects. The first project has the preliminary nature of the second project, and practices the process of visualizing the elements of the object and the process of maintaining and developing the value while changing the characteristics of the object. In the second project, students have to come to a conclusion by solving more complex problems considered human factors. Students were required to work on weekly assignments that developed the project concept, and the professor consistently conducted a weekly cycle of reviewing the contents and writing individual comments and delivering them to the students in class. This continuous cycle process is the most important characteristic of this class. In addition, ten case studies were used as a way to learn from other cases and from each other.

Thus, the project, the continuous task-feedback cycle process, and the case study were integrated into one learning system. Through this, design concept, principle, process, method, etc., which is the aim of this lesson, were communicated and taught, and other detailed technical matters could be embodied in students. Through the autobiographical way of looking at the class, the researcher was able to reflect on the strengths and weaknesses of the class system and to draw implications for future improvement. Later on, individual teaching methods need to be shared more in this form. The accumulation of the evaluation of the effect of teaching methods and contents on the basis of sharing will help build the 'knowledge system' and 'work logic' common to industrial design.

Associate Professor of Industrial Design and Design Management at Yonsei University. He is also responsible for the Interdisciplinary Graduate Program in Design Management at the university. He has been interested in the nature of design research and how to teach design to various audiences. The intangible trends of industrial design and the relationship between man and the artificial world have become a topic for him recently.
Product Identity Footprint: A Set Of Tools To Clarify The Front End Of Industrial Design Projects In Order To Start And Develop Products The Right Way.

Rodriguez Cuevas, JM. RODZ+, Toluca, Mexico, rodzmas@gmail.com
Islas Munoz, JA. University of Cincinnati, Cincinnati, USA, juanantonio.islasmunoz@uc.edu

Abstract

Having observed that many industrial design projects are started with the wrong approach, producing loss of resources, time, and professional relationships, this article presents a set of three tools that enables a clearer view of the Fuzzy Front-end (Vogel, Cagan). The first tool helps to understand the design order (Buchanan) of the product to be developed, and to place it in the utilitarian product universe (practical and economically biased), the transitional-wholistic product universe (practical, economic, and emotionally balanced), or the emotional product universe (viscerally and symbolically biased). The second identifies a product’s global purpose composed by its practical, economic, and emotional purposes, as well as the value factors they include (practical and indicative function, usability, practical or emotional cost-benefit, visceral appeal, and symbolic meaning). The third tool involves the type of project to be undertaken (vision, new development, major enhancement, or minor enhancement). Applicable to all disciplines of design, the three tools comprise the product identity footprint, which helps inform the selection of appropriate strategies to start a project the right way. It can increase the efficiency of the product development process by providing an agreed view that can be shared with all the development team, from the project sponsor to the engineering, marketing, planning, and creative departments.

Keywords: industrial design methodology, design strategy, project development, design theory, industry

In his book “Making Ideas Happen,” Scott Belsky, founder and CEO of Behance mentions that one of the most relevant causes of ideas not seeing the light of day is that the idea itself does not have value until the pertinent actions to make it happen are taken. Thomas Edison mentions that for an idea to succeed, 1% of inspiration and 90% of perspiration are required. Materializing an idea through Belsky’s pertinent actions and Edison’s 90% or perspiration heavily depend on organization and structure. However, according to studies done for Belsky’s book, the creative guild is the most disorganized of all. A survey done through Behance shows that creatives reject structure while claiming that it constrains their creative instinct. Jorge Mauricio Rodriguez Cuevas has also seen a similar pattern through his 18 years of experience in industry and academia in Mexico. He has observed that people aspiring to work in the discipline of industrial design tend to be disorganized and fear processes and constraints, but embrace the self-expression and emotional potential that is closer to art, shown in their impactful renderings,
prototypes, and aesthetic interpretation. At the College of Design, Architecture, Art, and Planning, faculty member Juan Antonio Islas Munoz observes similar patterns. Students and professionals who adhere to the artistic and visually impactful side of design usually struggle when facing projects in which this is not a priority, while students who tend to be more functionally-driven suffer in projects that have a stronger emotional bias. One of the most common problems faced by design practitioners is negligence in decision-making of appropriate strategies to identify the type of challenge before a project is started. Important matters such as the selection of the right team to be assembled, and quantification of resources to face the project are not considered. There is the feeling that being creatives, good sketchers, or model-makers, is enough to direct and execute a design project. This is a quotidian reality, sometimes present in minor or major scale, but practically as an unfortunate constant.

Figure 1. Parking pay machines with different levels of structure and complexity.

Beginning a design project the right way is not easy. It is a complex endeavor that has even been called “The Fuzzy Front-end” (Vogel, Cagan). However, this is where structure and organization can help make this complex stage simpler for creatives. According to Norman, complexity can be made simple, as long as there is a legible structure with patterns that can be understood by the human mind. In turn, simplicity can quickly turn complex if the aforementioned structure does not exist, as can be seen in Figure 1. This document seeks to help clarify the Fuzzy Front-End by proposing a structure to the complexity of this stage.

Like other authors have done for decades, this paper proposes that industrial design is a blend
between the disciplines of art and engineering. However, it goes beyond that by emphasizing the varying levels of mixture and nuances possible as products get close to the rational dimension of engineering, or to the emotional dimension of art. Industrial Design products located close to either side require different approaches and resources for project development. This may seem obvious but, as it was specified before, it is not uncommon for industrial design projects to be executed with the same approach, regardless of where they are on the spectrum due to preference for self-expression over constraints and processes.

Designers are not the only protagonists in the complex world of product development, and applying the same approach to develop products in opposite sides of the spectrum is not exclusive to them. In industry, there are other groups such as the sponsor or company that requests the development, marketing teams, as well as engineering and planning ones. Each of them represents a different set of demands, requirements, and wishes, all related with the project’s objectives. However and odd-seemingly, even though they are all part of a group that seeks the same result, the understanding of the product to be developed can be different since these demands, requirements, and wishes are related to each group’s specific interests and particular contexts, which impacts their approach when developing a product. The following list exemplifies some of the actions or thinking states that are frequent in the teams about how the product should be developed:

1. The personality of the sponsor that commissions the development: this entity tends to have a preconceived notion or desire about what the product to be developed should be, which is not always related to the purpose that the product has to respond to.

2. The personality of the marketing team: this way of thinking can judge product development based on the information that user groups have provided, trends and fashionable style, or in reaction to the competition.

3. The personality of the planning team: planners normally focus on the project being executed according to what was stipulated in terms of time, as well as making sure that the development cost does not surpass what was initially calculated.

4. The personality of the engineering team: it normally seeks the least amount of impact of any kind so the product stays within cost while still functioning properly, and it adjusts to what the planners demand.

5. The personality of the design team: it normally has an idealistic vision that exceeds what the product should be, and despite having objective marketing data (to some extent), always seeks to push other teams to go beyond what is expected. This does not seem like a negative in principle, however, when the design team is young and inexperienced, it may not execute an objective plan or strategy that aligns to the requirements of the other teams. As it has been explained before, its passion and excitement over creation tend to win over following the constraints of boring but real requirements.

Summarizing, the lack of a correct and well-established judgement by all the team involved in the development of a product, is the main cause of the possible failure in the project’s results. This is why it is important to have a set of tools that help clarify the pertinent priorities specific to the project, so that all teams involved have a common understanding and thus become able to work together in a more unified way. The tools presented in this paper are useful for the
project leader (designer or otherwise) to create awareness and persuade all teams involved about these pertinent priorities.

The spectrum of industrial design product universes proposed in this document is composed by three categories: the Utilitarian Universe (practical and economically biased products) the Transitional-Wholistic Universe (practical, economically, and emotionally balanced products), and the Emotional Universe (visceral and symbolic biased products). Its correct and deep understanding and the priorities related to them, in addition to the type of project that is being developed, and the design order (Buchanan) involved, are proposed to be used as a set of tools to create a Product Identity Footprint. Its objective is to clarify the front end of projects, and help product development teams and leaders understand which approach within the spectrum of rationality or emotionality, is appropriate to take before the execution of a design project.

**Theoretical foundation**

Industrial design as a spectrum between engineering and art

The classification proposed in this document considers different universes of industrial design products, as they are set in the scale that transitions from Engineering to Art. In order to understand these universes, it is important to review the fundamental differences between the products of both worlds.

**Engineering products.**

The main purpose of engineering is to materialize human ideas in the field of the practical and the operational. Exact disciplines and specific processes are applied to bring engineering products to life with the highest level of effectiveness possible, which means achieving the desired result (efficacy), with the least amount of resources possible (efficiency). Engineering products are rational and concrete.

![Figure 2. Examples of engineering products.](image)

**Art objects:**

Differently, art’s sole reason of existence is to express the emotions of the artist and/or to provoke them in the audience. Art products are capricious and abstract. Their purpose is to try and satisfy the senses or give a non-logical answer to the great need of humans to express our nature, condition, insecurity, or security. Art products do not need to be tied to a practical purpose, solve a problem, or have a utility to exist. They are not necessarily brought to life with efficiency, but with whatever means are necessary to make them exist.
Industrial Design products are a mixture of the hard disciplines from engineering, and the expression and human perception disciplines from art. They can be both rational and concrete, capricious and abstract, or a mixture of both. Industrial Design represents an appropriate, strategic, and precise balance (or imbalance) between both worlds, with no identifiable border of when one starts and the other ends, but with a progressive variation of the logical, objective, and rational to the emotional, subjective, and irrational.

The purpose of products

In Aristotle’s rhetoric, the discourse is the means in which an orator tries to transmit a message, which should be understood in the best way possible by the listener. In order to achieve this, Aristotle divides the discourse into three main dimensions. The first one is called logos, which is of a rational order and has to do with the objective definition of the message: its practical purpose. The second and third dimensions of the discourse are of an emotional nature. The second dimension is called the ethos, which is related to the attitude, conduct, and character in which the orator emits the message, which in turns aims to create an emotional sense of certainty and credibility in the listener. The third dimension is called pathos, which has a symbolic nature by generating an emotional impact in the listener, this time by connecting with other experiences or feelings. Summarizing, the logos of a discourse is its practical purpose, the ethos is the emotional sense of the orator’s credibility, and the pathos is the listener’s emotional identification with what is being said, and how it is being said. Products are analogous to Aristotle’s ideas in the way that they also have a practical purpose, which is related to the effectiveness of their function, as well as an emotional purpose, which aims to produce a response in the user related to the pathos, which is backed up by the product’s or brand’s ethos. In addition, products also have an economic purpose which can have two foci. The first one is to get the best practical cost-benefit by seeking to materialize the product in the most efficient way, with the least amount of resources in their operation, fabrication, maintenance, etc. The second one is to get the best emotional-cost benefit by seeking to maximize the impact of the product by means of visceral appeal and symbolic meaning.

Like a speech, before beginning a project to develop an industrial design product, it is important to identify what needs to be achieved. This depends on where the product is located in the spectrum from engineering to art. Engineering products prioritize the practical and economic purposes, less relevant for art products, which prioritize the emotional purpose. For industrial design, all three purposes coexist in a global purpose, which changes by the way the practical, economic, and emotional purposes are balanced depending on their location in the spectrum.
The practical and economic purpose outweigh the emotional purpose if the industrial design product is closer to engineering than art, and vice versa. Figure 4 shows how the balance shifts as products transition from one side of the spectrum to the other.

Figure 4. In the spectrum of engineering to art, the global purpose of products is balanced differently.

A series of value factors can be used as arguments to help pertinently prioritize the importance of each of the three purposes when developing an industrial design product. Their importance and relevance in the conversation varies depending on where they can be placed in the spectrum from engineering to art. The value factors can be observed in Table 1.

<table>
<thead>
<tr>
<th>Rational value factors</th>
<th>Practical purpose</th>
<th>Economic purpose</th>
<th>Emotional purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Practical Function: considers the correct operation of the product, its utility, durability and endurance, etc. It is object-centric.</td>
<td>Practical cost-benefit: considers manufacturing cost and its implications in terms of final price, quality, etc. It is also related to making the product perform and operate.</td>
<td>Emotional cost-benefit: considers the resources used to obtain the maximum effect possible in their audience.</td>
<td>Visceral appeal (Norman): considers the desired initial reaction of the person that comes in contact with the product. Symbolic meaning: considers the reflective relationship (Norman) between an object and the person’s values and background.</td>
</tr>
</tbody>
</table>

Figure 5. Rational and emotional value factors as related to the product purposes
If the product is closer to the rational side of the spectrum, it can be argued that the focus on the practical purpose’s value factors (practical function, indicative function, and usability) should be stronger than the emotional one (visceral appeal and symbolic meaning), and that a practical-cost benefit should be the focus on the economic purpose rather than an emotional-cost benefit.

The three universes of industrial design products

The understanding of the different weighting of a product’s purposes and their value factors makes it possible to identify three main categories: the Utilitarian Product Universe, the Transitional-Wholistic Product Universe, and the Emotional Product Universe. It is important to mention that there is no border in-between these categories but rather a progressive transformation from one to the other.

Figure 6. Examples of products in the Utilitarian Product Universe (practical and economically biased)

The Utilitarian Product Universe exists next to the engineering side of the spectrum. The goal of the products in this universe is to provide a service in the best way and at the lowest cost possible, which means that their practical and economic (with a practical cost-benefit focus) purposes are a priority. In this universe of products, aesthetic considerations are not necessarily non-existent, but any application depends on enhancing performance or indicating the function and correct use of the product rather than to produce emotion. Usability can be a priority since it increases productivity. Utilitarian products are more object-centric than user-centric the closer they are to the engineering side of the spectrum. A person that pretends to purchase a product in the Utilitarian Universe considers the following decision-making factors: first, the product should operate correctly and be capable of solving the problem or need with the highest productivity possible; second, the product should have a fair price in relation to quality, warranty, productivity, part availability, maintenance cost, post-sale service, etc.
The Transitional-wholistic Universe (Figure 5) encompasses the products that are in the middle of the transition between engineering and art. In this case, the practical, economic (both types of cost-benefit), and emotional purposes have an equal weight distribution and reach a true balance. Usability becomes more important as well and products become more user-centric. Transitional-wholistic products are designed to be sold globally and are intended to be used by culturally diverse people, with different physical constitutions, languages, lifestyles, etc. Due to their complexity, they are developed by big corporations with the appropriate infrastructure, economic resources, and specialized, multidisciplinary staff. Products within this universe present a more sophisticated appearance and nuanced function than the ones in the Utilitarian Product Universe. In the Transitional-wholistic Product Universe, form is derived from function, as much as function is derived from form. Since all value factors have the same weight, the persuasion tools for purchasing these kind of products becomes more complex. Generally speaking, a person that is looking to purchase a product in this universe wants it to work as intended, be affordable, be visually appealing, and resonate with their personal emotions at the same time. This may produce an indecision conflict in the buyer, who will have to decide if to buy the most effective, the most affordable, or the most emotionally appealing product.
Lastly, the Emotional Product Universe (Figure 6), is represented by those products in which the emotional purpose is the most important, and thus the economic purpose has an emotional cost-benefit focus. Generally, consumers of these type of products are persuaded by the style, brand, and lifestyle they inspire. They are aspirational products whose only purchase justification is tied to an emotional thinking structure. In this universe, the practical and economic purpose values are not relevant, and are overcome by the product’s visceral and symbolic appeal. A buyer of these products would base their purchase decision in phrases such as: “This is beautiful, I need to have it!” “People will know how smart I am if I buy this,” “Not everyone can have one of these,” “I don’t know if I will use this, but it would look great in my living room,” etc.

Figure 7 shows the three universes going from the rational dimension of the engineering discipline to the emotional dimension of art in the X axis. At the bottom of the graph, the way the practical, economic (with both foci), and emotional purpose are balanced differently as products are located in different parts of the spectrum. Utilitarian products are more rational and concrete, and the emotional products are on the abstract and emotional side. In the Y axis, the curve and faces displayed represent the size of the market, and the expression of the faces moves from indifference to emotion as the spectrum advances.

Transitional-wholistic

![Figure 7. Industrial Design Product Universe infographic](image)

produced for large global markets and are frequently manufactured by the millions, and thus
have a larger consumer base. Utilitarian products, frequently tied to agriculture, transformation, manufacturing of goods, and purely functional objects, tend to have a smaller market share, but they can still be considered as large productions. Emotional products on the other hand are not tied to big sales, and thus have smaller markets, sometimes producing only hundreds, dozens, or even unique pieces.

**Figure 8. Buchanan’s 4 design orders interpreted as an automotive gage.**

**The 4 Design orders**

Another way to understand the complexity of a project is to identify the design order that the product to be developed will belong to. Dr. Richard Buchanan presents 4 orders related to the complexity of design: communication, construction, interaction, and systems (Figure 8). The first one encompasses the generation of solutions through bi-dimensional communication, the second one through the construction of tridimensional material objects, the third one through interactivity with physical objects with interfaces, and the fourth one through complex systems. As the design order increases in complexity, each order is inclusive of the next one (figure8): the design of tridimensional material objects includes communication, interaction includes 3D objects and communication, while systems include all three. Understanding the design order of the product to be developed helps identify what kind of expertise is necessary to take on the project before its execution.

**The different types of industrial design projects**
In addition, industrial design projects have different levels of complexities. The difference has to do with their objective and scope in relation to the project’s global purpose. The different project types are:

- **Vision projects**: their primary goals are to make its output influence the direction a company could take in future long-term projects, or to communicate the company’s intentions to their audience if the direction has already been selected. The point is to generate a conversation within and without the company either to convince high executives on what the company could be pursuing, or to inform them by gaging the reaction of the market to this new idea. Examples of these projects are concept cars presented at auto shows.

- **New developments**: they begin from the ground up, with nothing or little being pre-established. Their objective is to break paradigms and have the highest opportunity for innovation, and thus, to be revolutionary in the marketplace. In this case, the research phase is the longest and most thorough. Its development requires the most resources in terms of time and money, since more needs to be created from scratch, and more human expertise is needed. Thus, the cost and duration of a project of this nature is higher.

- **Major enhancement projects**: they have the objective of increasing the life of a product that is already in the market but has begun to lose sales, without the high investment needed for a new development. Under this evolutionary scenario, projects start from well-established foundations, previous work, existing assets and parts, etc. The project cost and duration is much lower than the previous category, involving the use of a great percentage of existing components from previous versions of the product. The enhancements done to the product are focused in performance and/or usability, cost reduction, and stylistic refresh.

- **Minor enhancement projects**: their impact usually lies in aesthetic and other minor updates, leaving the original product architecture, functional components, and manufacturing processes practically untouched. A project of this nature is useful to further increase the life of a product that has already been under major enhancement. This type of project requires the least amount of resources and duration.
design projects.

Figure 9 shows the life cycle of a product that begins with a short vision project, which leads to a long innovation one. The decreasing area going into the diameter of the largest circle depicts the product’s fall of sales as time passes. The product could be discontinued or receive a major or minor enhancement to extend its life. As the new product loses sales again, it could receive a minor enhancement yet again.

Understanding the type of project to be developed before starting is crucial, since the most appropriate one can be selected in relation to the times and resources of the company has. It helps make the decision to avoid jumping into a project that will require a significantly higher investment than originally envisioned, or to take actions to find the right partnerships and secure the level of investment necessary before beginning.

**Product Identity Footprint**

The theoretical foundation explained earlier was used as a base to create a set of tools formed by three main components: the Design Order and Product Universe Coordinate Chart, the identification of the Type of Industrial Design Project, and the Value Factor Prioritization Tool. The addition of these components helps understand the magnitude of the endeavor, and allows for its execution to begin in an appropriate way and down the right path.
In order to obtain a deeper understanding about the subject matter of this document, we have built upon Buchanan’s design orders. Within the communication order, a section for the design of intangible assets (e.g. audio) has been added. With this, the delivery of design solutions can be in the dimension of the non-visual, 2D, 3D, and 4D (3D plus interaction). We have also correlated the design orders with levels of information perception and interaction, starting with information (intangible, physical, and digital), and interaction (physical, digital, and smart), ending with systemic, which can include some or all of the aforementioned. This can be correlated with the product universe classification. Although this paper concerns itself mainly with industrial design products, the model can be extrapolated to all four orders of design, as seen in Figure 10, which shows examples of different design solutions pertaining to each order and universe. This chart can serve as a coordinate system to identify which is the complexity of the product to be developed by placing it in its corresponding order of design and universe. By showing the dimension of the delivery of design solutions, and the perception and interaction level that it will require, the chart can offer insight on the project needs in terms of the involved disciplines and the human resource expertise required. This in turn allows for a better understanding of the project scope, the development of a product development strategy for the execution of the project, as well as a more accurate economic panorama of what will be necessary to materialize it.
The tool displayed in Figure 11, is formed by concentric circles divided radially. The blue area houses the practical purpose, the purple area the economic purpose, and the red one the emotional purpose. Inside each type of purpose, the value factors are indicated. The shade of purple used in the economic purpose varies to be closer to blue for the practical cost-benefit, and closer to red for the emotional cost-benefit. When ranking, levels 1-2 indicate low or no priority, 2-3 mid-priority, and 5-6 high priority. It is important to note that aesthetics involve both the practical and emotional purposes.

The following pages show how to fill the tool using three chairs as an example: a utilitarian, a transitional-holistic, and an emotional one. The value system in (Figure 12) is proposed. Figures 13, 14, and 15 show a set of auxiliary charts to be used to analyze every product prior to filling the circular tool. They are meant to rationally describe the product’s purposes, as well as the value factors involved in each. Filling these tables with input from all the development team is crucial for the understanding of what should be prioritized during the project.
<table>

</tbody>
</table>

Figure 12. Rating system for the value factors prioritization tool
In the case of the utilitarian chair (Figure 13), the practical purpose is more important and thus it is clear that allocating time and resources to improve the visceral and symbolic meaning is not an appropriate strategy. The transitional-wholistic one (Figure 14) is more balanced, making this a more complex project since it needs to fulfill both practical and emotional purposes. Lastly, in the emotional chair (Figure 15), the designer can have free rein to explore the product’s visceral and symbolic appeal, as fulfilling the emotional purpose is key.
The data from these tables is used to fill the Value Factor Prioritization tool which can be used to better visually display the reasoning behind the arguments to lead the product development. Figures 16 shows the comparison of the value factors of the three chairs. It can be used to generate the project strategy and be brought up by any product development team member whenever the project starts going astray from the appropriate and agreed path.
Figure 15. Auxiliary chart evaluating the Flux chair

<table>
<thead>
<tr>
<th>PRODUCT</th>
<th>Flux chair</th>
</tr>
</thead>
</table>

**PRACTICAL PURPOSE**  
Provide seating in the home environment and fold flat for storage.

- **Usability**
  - Comfort and human factors are not a priority. The chair forces the user to sit in a specific way without posture guidance.
  - Indicative function
    - It is also very difficult to assemble, requiring video tutorials online.
  - Practical function
    - Not very important, the product is more a piece of decoration than an actual piece of furniture so it only needs to comply with its function for short periods of time with little frequency. The chair has good reviews on wear but they also mention it has disassembled while in use.

- **ECONOMIC PURPOSE**
  - Practical cost-benefit
    - Not very important as it is more a piece of decoration than a high-use product.
  - Emotional cost-benefit
    - Very important, all the resources are put into the materiality and looks rather than function and use.

- **EMOTIONAL PURPOSE**
  - Visceral appeal
    - Highly important. It should stand out in the home environment.
  - Symbolic meaning
    - It seeks to be unique and thus make the user feel unique in turn.

Figure 16. Comparison of the value factor prioritization tools with chairs in different product universe
Putting it all together

Figure 17 shows the product identity footprint of what could be a project to develop based on the generic metallic folding chair featured in the examples of previous sections. In this theoretical exercise, a company wants to develop the next generation of this chair. Their marketing team has

Type of project

![Value factor prioritization tool](image)

![Type of project](image)

Figure 17. Auxiliary chart evaluating the Flux chair
defined that the product needs a full renovation rather than only enhancement, and that the visceral appeal of the product needs to be improved from its previous iteration.

The Design Order and Product Universe Coordinate chart shows that the chair belongs to the utilitarian universe of products. It indicates that it will be part of the construction order of design and thus a 3D material object that people will need to physically interact with, and that it should communicate its use as well. The Value Factor Prioritization tool shows that the practical purpose is the priority and thus its practical function, indicative function, and usability are of high priority for development. The emotional purpose is less important but the visceral appeal has to be sufficient. It also shows that the economic purpose is focused on a practical cost-benefit and that this is its highest priority. Since the emotional purpose is of the lowest priority, it is then clear that all resources and efforts from the development team will be focused on the practical purpose. The Type of Project is a new development in the example, which means that there is a high opportunity for innovation, and that the project will be require more time and financial resources for its development.

All of this understanding can help define:

- The disciplines involved: industrial design and product engineering.
- Human resource expertise: mechanical engineers specialized in metal-mechanic processes, and an industrial designer focused in specialized furniture.
- Design and manufacturing strategy: it is necessary to start by defining the functional architecture of the product, which should provide a satisfactory user-chair interaction. Part and component optimization, as well as minimizing the amount of manufacturing processes and materials is crucial. The strategy should consider the existing manufacturing capabilities of the project sponsor or the acquisition of the needed machinery or outsourcing of the process. The same is to be said about the resources of the project sponsor. If not sufficient, a different strategy needs to be selected or partnerships generated. Any applications related to the emotional purpose need to adjust to the practical purpose and the company's manufacturing capabilities.
- A real economic and time panorama for the project: with this information it is possible for the company to establish a more accurate amount of money and timeframe for the project development.

Conclusion

The Product Identity Footprint provides a wealth of information prior to starting a project that clarifies the fuzzy front-end of product development. It achieves this by providing understanding of the design order and the product universe it belongs to in the spectrum from the rationality of engineering to the emotion of art, specifying if it is a utilitarian product (practical and economically biased), a transitional-wholistic product (practical, economic, and emotionally balanced), or an emotional product (viscerally and symbolically biased). It helps identify the global purpose of the product to be developed and its practical, economic, and emotional components, as well as the value factors involved in each one. This knowledge is used to
identify and understand to the type of project to be undertaken (vision project, new development, major or minor enhancement). The addition of all this helps generate an appropriate strategy to begin an industrial design project in the right way. It is also applicable to other design disciplines. The product identity footprint should help make projects more efficient, avoiding misunderstanding and focusing all the development team’s efforts towards a common goal. This is particularly useful for designers and other creatives, since we are not used to structure and frequently rely too much in our artistic intuition.

The work presented in this document is just part of a bigger model that is currently in development. Because of this, the proposed tools solve only part of the fuzzy-front end. It is still necessary to develop a market analysis tool to validate that the product identity footprint generated by creatives and their development teams will lead to a blue ocean or market gap, rather than a red one with a saturated market (Kim, W. C., & Mauborgne, R.). Another tool that would be a useful addition should delve deeper on identifying the desired attributes of the development team beyond the required disciplines.

A limitation of the set of tools presented in this document, is that a significantly experienced creative leader is more likely to understand all the concepts presented in the document, while most of the problems described are caused by inexperienced creatives. However, it can still help them make a faster and less painful transition to being in control of their projects, allowing them to become instrumental to their success, and thus cultivate productive and long-lasting professional relationships.

Authors biographies

Jorge Mauricio Rodriguez Cuevas

Jorge Rodríguez graduated with honors from the Center for Industrial Design Research, from the National Autonomous University of Mexico. During his college years, he developed transportation projects that promoted the use of solar and electric energy sources, competing in the Sunrace’95, US, and the “World Solar Challenge’97” in Australia. Between 1997 and 2005, he worked at the General Motors Advanced Design Center in Toluca, Mexico; GM Technical Development Center in Detroit, Michigan and GM Sao Paulo Brazil, developing projects for Chevrolet, Cadillac, Saturn, Pontiac, and Buick. In 2004, he obtained the “Chairman’s Honors Award” for his work. Between 2001 and 2003 he studied Automotive Design and Visual Communication at the College of Creative Studies in Detroit, and Digital Modeling at the University of Purdue, Indiana. Between 2005 and 2010 he co-partnered Hunpel, a product, and mobility consultancy, where he worked as Research and Development Director. He currently works under his own brand RODZ+ offering consulting services in several areas as advanced industrial design, innovation, and UX/UI, mainly for companies like Ford Motor Company, AUDI, Chrysler and Mazda among the most important. Also, he worked as a professor in several important universities in Mexico, as well as the University of Cincinnati.
Juan Antonio Islas Munoz

Juan Antonio Islas Munoz is a Master of Design graduate from the University of Cincinnati and has an industrial design degree from Universidad Autonoma de San Luis Potosi, Mexico. From 2007-2011, he worked at Rigoletti Casa de Diseno as an instructor and designer in Mexico City. During this time, he worked managing projects and designing toys for Lactius de Mexico, Octopus Brands, and Conectado Design Studio. In 2011 he obtained a Fulbright scholarship for his graduate studies, in which he researched automotive design aesthetic perception and digital sculpting software for the same discipline. He is currently an Assistant Professor of industrial design at the College of Design, Architecture, Art, and Planning of the University of Cincinnati, where he has focused in visualization for industrial design, multidisciplinary collaborative projects and currently leads the transportation design program. In his current position, has executed design projects for Autodesk, Crown Lift Trucks, General Motors, Fiat Chrysler Automobiles, Boeing, P&G, Pfizer, and Cincinnati Children’s Hospital.
Critical & Speculative Design Practice and Semiotics: Meaning-Crafting for Futures Ready Brands

Malex Salamanques, Space Doctors, Brighton, UK, m.salamanques@space-doctors.com

Abstract

This article concerns the use of critical design practices within the context of commercial semiotics, arguing that incorporating practices from a critical design approach is valuable for client brands, but also an important means with which to incite brands to consider more deeply their role in shaping the future. As an alternative to the oppositional approach frequently taken by critical design practitioners, working through design practices collaboratively alongside client brands creates potential for the radical changes sought by many of the movement’s vanguard. A case study of recent work with a corporate client demonstrates the practical effects of using critical design practice within a commercial setting, proving the complementarity between critical design practice and commercial semiotics – where the confluence of the thinking brought new value to improve product design for example – and points to the value of using current leading edge thinking within the design community.

Keywords: commercial semiotics, critical design, product design, innovation, brands

Commercial Semiotics and Design

As a commercial semiotics agency, we bring many tools to bear in order to help brands better understand themselves in order to better express themselves. We contend that the best approach to solving questions of communication is to look at the problem through the lens of semiotics, and we further contend that everything communicates. At root, semiotics is the discipline that studies ‘signs’ and ‘sign systems’. Eco (Eco 1976, 7) offers one of the broadest definition:

“Semiotics is concerned about everything that can be taken as a sign”. A sign is anything that holds meaning, from a single word to a colour or the feel of a material choice, through to an abstract concept, but it will be interpreted in drastically different ways depending on the context in which it’s received. Mirroring Stuart Hall’s work in theorizing television—stipulating that there are multiple readings of television broadcasts based on a subject’s personal and political standpoint—commercial semiotics takes brand communications to be as susceptible to multiplicities of interpretation subject to context as any other media. As Hall argues, however broadcasts are ‘encoded’, the disseminator does not have the ultimate power to dictate how they are received. They will be ‘decoded’ in differing ways dependent on context (Hall 1979). In just the same way, people love or hate brands depending on how they
interplay with the wider stories of these individuals’ lives, because of how they reflect these individuals’ personalities, because of what they mean.

We investigate the current state of culture, as expressed through mass media, through art, and through commerce, to give a deeper understanding of these social and cultural contexts and the stories they form. We establish the broad trajectories of people’s understandings of key concepts—how the ideal form and expression of masculinity has changed and will change, for example—to help brands stay abreast of emergent culture, to keep their eye focused firmly on the future, and to help them understand that as brands, not only does their meaning depend on people’s understandings of broader culture and of other brands, but they themselves take a key role as meaning-makers.

Brands are enmeshed in a complex relationship with mass culture, creating messages that themselves become pop culture monuments (“Wassup?!”) and iconic design elements which are laden with the weight of the brand’s meanings both intended and accidental (Dove's latest “body shape” bottles, intending to communicate “real beauty” and actually delivering “off the shelf” simplified beauty types. (Jones, 2017). Sudden, seismic shifts in the political climate have recently brought this even more clearly to light. Brands can no longer afford to remain neutral and apolitical, as this in itself can be read as a tacit endorsement of the incumbent government or a weak lack of open support for fear of alienating consumers from the opposition, depending on the stance of the interpreter.

Not just ‘messages’ from brands, but also their material products and artifacts are decoded within social and cultural contexts that deeply affect the meanings attributed to them. The mindset of a designer brings “a designerly way of thinking” (Archer 1979, 17) to bear to answer questions of how objects are understood and how it is they express their meaning, with specialist knowledge of material culture from ergonomics to the latent symbolism of a particular typeface, depending on their areas of interest and expertise. Located at the interface of industry, the market, technology and culture, design is eminently suited for engaging in culturally critical exercises that focus on the symbolic function of products (Bonsiepe 2007, 30-31).

Through understanding the nuances of how shape, texture, material, and so on feed into a product’s meaning, brands are better placed to shape their products to express the meanings they intend rather than take a punt on having them mean what they will. Design and semiotics interplay (as Design Semiotics) to give the deepest understanding of a brand and its artifacts possible, and help brands think about how in crafting their material output they are also crafting the meaning of these products and their brand as a whole.

**The Changing Role of Brands and Design**

We live in ‘exciting times’, and commercial clients are acutely aware of the uncertainty of our collective future. In recent years, it has become ever more clear that very few brands can survive based on a model of simply selling products. Similarly, the idea that brands can provide ‘consumers’ with meaningful identities simply through the consumption of their products is outmoded, and brands attempting to offer identity without substance are quickly rejected. Instead, brands need to learn how to embody a purpose—a higher meaning that
recognizes the brands interplay with culture writ large. Take, for example, Patagonia’s “Don’t Buy This Jacket” campaign (Figure 1)—a prototypical example of how a communications campaign flipped expectations on their head to underline the brand’s progressive conservatism and align themselves with a resurgent interest in ethical consumerism.

(Figure 1: Patagonia’s “Don’t Buy This Jacket” advertising campaign, 2015)

Of course, it isn’t just the words Patagonia use that form the story they tell. Every element of the brand—the smell of a jacket’s lining through to the shape of the hangers used in stores—feeds into the narratives built around the brand. Patagonia have managed to forge a compelling narrative that chimes with prevalent concerns around ecology, catastrophe, and the anthropocene. Patagonia’s wares may appear very functional—the brand creates clothing lauded for its practicality—but also embody how design has moved beyond older modernist assumptions that “form follows function” (Sullivan 1896) to a more constructivist stance wherein an object is taken to have “meaningful presence” (Malpass 2017), a presence onto which observer’s and users project their own wider meanings based on their context.

As the role of brands is changing rapidly, we need to keep our approach nimble. At present, the practice of ‘affirmative design’ is prevalent within industrial and commercial circles, directed at solving identified problems and providing iterative progress (more blades, less weight, cheaper materials, etc.). As brand consultants, we are experts in helping brands to tell their stories, and a vital part of this is a willingness to draw attention to areas of tension—to elements in campaigns that jar or pull against a brand’s established identity. As designers, we are already adept at taking a client’s stated aims and providing the products they desire, but these may not be the products they, or the world, need. We need to be less afraid to critique, and as such are incorporating methodologies drawn from critical design practice into our hybrid of design semiotics. It can be difficult to work up fine-grained methodological distinctions between critical/‘uncritical’ design—it is, after all, “more of an attitude than anything else, a position rather than a method” (Dunne & Raby 2017). We believe that it is the focus on engagement rather than optimization, on broadening thinking rather than solely providing solutions, that marks out a critical practice, and it is this we are bringing to bear in our commercial work.

Critical design practices widen the scope of application of design thinking we provide our clients, including (but not limited to) practices of provocation—ideas of ‘broken futures’
clients may need to prepare for—of introducing multiple speculative futures, and of building, or better yet helping to inspire the building of, ‘diegetic prototypes’ for these potential futures. That is, we help clients design for futures they would otherwise never have imagined, and help them see their place within them.

Diegetic prototypes are a valuable means with which to demonstrate that designed products are far more than merely functional objects. Though they may be created for some particular use or to provide some discrete function, objects have a symbolic function beyond the utilitarian. Artifacts are instilled with moral values and norms, or have these values attached to them by patterns of use. The plastic six-pack holder is eminently useful, but is now taken by many as a microcosm for industrial-scale waste, plastic pollution, and humanity’s impact on the animal kingdom. Running leggings and yoga pants are worn perhaps more often in casual social circumstances than at the gym or studio. Athleisure fashion rides on the explicit function of these garments, attempting to connote a wider lifestyle of radiant good health and holistic mental wellbeing, without requiring the products be used as initially intended. Of course, a brand can’t control exactly how users decode their output, whether communicative or material, but they can take steps to promote favorable interpretations and usage that sit in line with the trajectories of a culture.

As semioticians, we have long incorporated critical elements of thought regarding our current social, economic, and political conditions and asked what they mean for brands now, with an eye to building an image of the future. Now, with critical design semiotics, we can more thoroughly work through the implications of these changes and trajectories, fleshing out our understanding of what the future will bring and preparing for those circumstances. Of course, given that users generate their own wide array of meanings when confronted with ‘meaningfully present’ objects, we can’t claim the ability to narrowly establish exactly what a given object means. We can, however, anticipate many of the meanings attributable and many of the techniques by which these meanings can be modified (e.g. by introducing anthropomorphic elements of textural design into gadgetry, we make it more likely it will appear ‘friendly’, but simultaneously widen the scope for sexually-charged ‘decodings’ of these products). It is by recognizing our inability to narrowly parse possible interpretations of a product that we can ensure we try to cover as broad a range as possible of plausible interpretations. We can use these limitations as a spur to broaden our thinking as much as possible to anticipate any and all potential users, going well beyond the narrow personas and idealized ‘users’ all too commonly seen in user experience design and associated fields.

The incorporation of design thinking—especially of modeling and prototyping—can make the themes and issues at play in projects tangible in a way that often inspires deeper meditation than theoretical critique. It foregrounds the meaningful presence of potential objects over and above their utility, and allows for deeper investigation of these products’ symbolism and meaning within real life than a purely immaterial or conceptual form of speculation. Retaining the messiness and grit of the everyday in workshopping these ideas isn’t just cheaper and easier; it’s necessary for a realistic envisioning of the future. Technological accretion means all material culture develops along a continual path, and although technology may become obsolete, it doesn’t vanish. Our cupboards are bursting with old cables, outmoded appliances, and so on, and this eventual obsolescence is an important part of a product’s meaning through time. How will an object’s meaning change across the time it exists? What will it come to
mean by the end of its lifespan? These might be impossible questions to answer with unwavering confidence, but they provide invaluable input into how quickly we can see an idea becoming passé or how an object might be coopted for a less utopian use than might be intended. Consideration of these questions can be an invaluable tool for future-proofing a brand against next year’s clichés or an unfortunate confrontation with the lightning-quick satire of meme culture.

The materially speculative elements of critical design practice ask us how and why we engage with emerging technologies to critique our present use and think through the potential implications it brings. Design fictions, artifacts and products created for an imagined future, help us see the world how it might be. Just as speculative fiction is marked out by its plausibility, delineated from pure fiction by its possibility, strong ties to currents within culture and realism mark out good speculative design. It must incorporate elements of utopian dreaming and dystopian imagination, but remain tied to actual developments in attitudes and behaviors. Semiotics provides us with a valuable toolkit for laying out visions of the future for this speculative design process to work with, and as such a hybrid practice is mutually beneficial.

Critical design practices need to be applied to commercial projects in order to effect the radical changes envisioned by critical design practitioners. Too often, “critical design activity is not considered product design… in the majority of instances it is described as art” (Malpass 2017, 7). But using critical design practice within commercial semiotics offers the perfect opportunity to bridge this imagined gap between the rarified world of artistic practice and the much wider everyday. We can work with clients to demonstrate how social, political and cultural values affect their innovations and vice versa, how their innovations then feed back into society and spark their own changes. Designers can no longer “masquerade as radical because of the violence and shock in their propositions” (Malpass 2017, 3)—we must engage with the brands that create such a quantity of our material world, and drive so much of the meaning we make of it.

**Case study**

A recent case study may help illuminate the value of critical design mindset in a commercial context, and how it can lead to radical rethinking of a brand’s function and status in multiple possible futures. We were asked to help a client understand the concepts of ‘effective’ and ‘harmless’ in both China and the US, and how they could resolve the tension between the two. How could their new product express itself as ‘effective’ while remaining ‘harmless’?

Semiotic analysis of the root understandings of ‘effectiveness’ and ‘harmlessness’ in both markets enabled us to build four potent resolutions of the issue built around syntheses of burgeoning ideas of the two concepts set to become mainstream understandings. That is, we took emerging idea of ‘effectiveness’ informed by, amongst other things, new relationships with smart technology, and ideas of ‘harmlessness’ informed by nascent attitudes toward new forms of genetic engineering and collided these ideas to form hybrids that could communicate both ideas simultaneously.

We understood, however, that building these resolutions was not in itself enough. These could form the backbone of a communications campaign for the present, but these possibilities
needed stress testing against uncertain futures to provide the building material for effective innovation. It was imperative that the client be embedded in the process for it to have any lasting impact within the brand, so we undertook speculative design workshops with the client to involve them deeply in the design and storytelling process.

We started by sketching a map of four future scenarios, built around axes concerning the severity of the issue in question, and of consumer attitudes to this issue. These futures—as in Peter Frase’s recent analysis of the future of capitalism, *Four Futures*—offer a set of ‘possible distributive scenarios’ rather than discrete realities. That is to say, they stood as four ideal types, but that any real future scenario is likely to fall somewhere in the blurred space between them.

As ideal types, they functioned as tools with which to test how products built around each of our four resolutions would react and respond. These tests helped us generate new ideas and possibilities, but perhaps more importantly they provided a concrete, interactive, and evocative picture of the world in which the client brand will operate in the near future, and the role the brand might take in this world. We incorporated elements of utopian dreaming and dystopian imagination into the process, and it called into question their whole approach to prototyping and projection for the future. Rather than a form of iterative progress, we saw the client deeply involved in a broader mode of thinking that encompassed scenarios from the extreme to the prosaic. We introduced ‘wild card’ scenarios—what if a heavy tax was levied on household waste? How would you adapt products to be refilled/reused? to ensure wider social issues were kept in play. We also foregrounded consideration of ‘extreme users’—those who totally break the mold of the client’s current base—to highlight how users change, how niche behaviors can easily become dominant, and how narrowing your scope to design solely for those you already appeal to can be a dangerous game.

Crucially, in asking the client to work with us to build models, we focused on rough and ready, lo-fi prototypes that were not supposed to be accurate representations of future products. Rather, they were built to act as tools for thinking. This is low-cost and carries no risk, and as such it’s no surprise clients are happy to jump in with both feet. Clients weren’t opposed to stretching their current models of thinking with the input of critical design methodologies; in fact, they were invigorated by the activity, and found the exploratory exercises profoundly informative. They were receptive to the fundamental claims that they are responsible for how they are understood both in terms of communications and product, and to the idea that we may need to overcome the marriage of design to purely utilitarian function and embrace a design for social function. We live in an era in which the benefits, indeed the necessity, of this type of process are clear, and we need to leverage opportunities to bring critical discourse into the commercial realm.

This workshop experience drove home how our role as designers can involve more than provision of simple problem-solution services to clients. We can, and indeed should, be provoking deeper thought about a client’s purpose, both for their benefit and in order to inspire the progressive changes many of us would like to see from the commercial sphere, the very same progressive tendencies that lie at the heart of critical design’s history. Critical design’s affective rather than explanatory nature, opening dialogues rather than answering questions, is its real strength in building collective answers to client questions and design problems.
Conclusion

The value of critical practices applied commercially emerges clearly, and it seems equally clear that there are many potential wider societal benefits, too. Critical discourse has many inherently progressive elements as it is built on dissatisfaction with the status quo. Continuing to draw aspects of critical practice and applying them to the commercial sphere will be fundamental to our role in helping client brands shape the right meanings, tell the right stories, and create the right products. Of course, as critical discourse is accepted into the mainstream, it becomes harder to define it as ‘critical’, but we can rest assured that new forms of critique and new methodologies will come to light to test and question tomorrow’s mainstream. We will be ready.

Abstract

To prepare students to imagine desirable futures amidst current planetary level challenges, design educators must think and act in new ways. In this paper, we describe a pilot study that illustrates how educators might teach K-12 students and university design students to situate their making within transitional times in a volatile and exponentially changing world. We describe how to best situate students to align design thinking and learning with future foresight. Here we present a pilot test and evaluate how a university-level Design Futures course content, approach, and scaffolded instructional materials – can be adapted for use in K-12 Design Learning Challenges. We describe the K-12 design-based learning challenges/experiences developed and implemented by the Design Learning Network (DLN). The Design Futures course we describe in this paper is a required course for third year undergraduate students in the School of Design at Carnegie Mellon University. The “x” signifies a different type of design that aligns short-term action with long-term goals. The course integrates design thinking and learning with long-horizon future scenario foresight. Broadly speaking, we ask how might portions of a design course be taught and experienced by teachers and students of two different demographics: within the university (Design Undergraduates) and in K-12 (via DLN). This pilot study is descriptive in nature; in future work, we seek to assess learning outcomes across university and K-12 courses. We believe the approach described is relevant for lifelong learners (e.g., post-graduate-level, career development, transitional adult education).

Keywords: DEXIGN | Futures | Foresight | Scenarios | Design-Based-Learning | Flipped-learning

In a world of accelerated change, faculty and students are required to adapt and master new knowledge to address larger scale problems such as planetary sustainability. Design educators are challenged to teach to design for short-term and long-term timescales. Fortunately, Future Studies researchers already describe how to teach students greater agency within long-term timescale horizons (Hicks & Slaughter, 1998; Slaughter, 2008). Teaching Futures Studies methods in a design school or K-12 school poses pedagogical and logistical challenges to teaching practices. We ask:

How might we best prepare our students?

How might we make learning more efficient and “sticky”?

To explore these overarching questions, we discuss two cases: one at the university-level and at the K-12 level. First, we studied third year undergraduate design students enrolled in a required Futures course. By the end of the course, students were expected to be able to align short-term design action with long-term vision horizons. We used a flipped-class learning pedagogy to introduce students to new concepts outside of class in preparation to apply those concepts in class. Second, we collaborated with the Design Learning Network (DLN) operating in the K-12 setting to address the question of how might we best prepare college bound students to overcome constraints and afford building robust educational pipelines. The goal within the K-12 context was to engage students and educators in creative problem solving through inquiry-based learning, design challenges, and reflective practice. We investigated these questions:

*How might quality design learning be opened to a broader spectrum of students with varying academic levels (K-12-university-lifelong) and disciplinary backgrounds? And, how might we more effectively teach new design content and methods?*

**Recognizing barriers and opening access**

In the United States, an increasing number of K-12 students have limited access to the arts. According to the 2016 National Center for Educational Statistics Report on State Education Reform 27 states define the arts as a core or academic study. While all 50 states adopted some level of elementary and/or secondary arts education standards, only about half require arts education as a graduation requirement. Yet, only a handful of states require an arts-based assessment, and/or district-level accreditation to teach the subject. Decreased access to creative and applied arts classes is linked to limited K-12 arts education budgets.

Limited access to creative and applied arts classes further challenges high school students to prepare a visual portfolio needed to apply to design schools. Unfortunately, most student portfolios show arts related content (e.g., art drawings, paintings) but do not include design projects. Drawing, while highly valued, is only one skill required for problem-based design challenges. This leads to college admissions decisions determining an applicant’s design potential weighing heavily on a narrow subset of skills exhibited in the individual’s portfolio.

This meritocratic practice favors students that have had more opportunities to develop the best portfolio. Thus, budget cuts to arts education in K-12 further skews the university-level admissions pool of students toward those with higher socioeconomic status (SES). We seek to relieve some of these pressures, enhance student learning, and open opportunities by providing K-12 students access to quality design education in areas like futures design and exposure to and practice with design thinking and learning, a highly applicable and transferrable skill.

**Recognizing design as a pathway to learning**

There is movement afoot, albeit slow, to integrate design thinking into learning. The draft 2017 Department of Education in South Carolina, College- and Career-Ready Standards for Design Proficiency offers K-12 design-thinking standards (pp. 98-135). In addition, private, philanthropic, and public initiatives emerged to offer K-12 students’ opportunities to focus on
creative problem-based studies alongside academics. Design schools actively engage pre-college students in summer programs, K-12 educators in professional development, and executive education innovation programs (Appendix A).

**Opening the pipeline to persistent design learning and thinking**

We aim to increase opportunities for students from all SES to consider design as a career path as well as to support teachers as they integrate design-centered instructional strategies into their teaching, thereby developing otherwise untapped design talent and leveraging diverse perspectives for solving societal-level challenges through design. We are interested in attracting better-prepared design school applicants, who are motivated by complex design challenges.

In the face of unprecedented global challenges, design is a frontline tool to transition towards long-term survival (Irwin, Tonkinwise, & Kossoff, 2013). Our approach increases access to futures thinking. For the individual student, design thinking and learning coupled with futures thinking gives tools to imagine their own futures and more fully explore potential learning pathways – it opens the space of possibility.

**CASE 1: Dexign Futures University-Level Required Course**

Typically, design is taught with studio-based courses: 15-20 students who meet over the course of 15 weeks, two times a week for 3 hours a day. The studio pedagogy allows students to receive rich feedback on projects from instructors and peers. The desk critique allows deep discussions with students individually during class. Traditional studio pedagogy has desirable features for learning, but there are limitations to the number of students this model can reach. We identified three student challenges from teaching prior versions of *Dexign Futures* courses with traditional studio pedagogy (Scupelli, & Wasserman, 2014; Scupelli, Wasserman, & Brooks, 2016):

1) limited critical engagement with futures thinking.

2) superficial interpretations of futures signs, forces of change, and benchmark goals for desirable futures.

3) limited application of futures methodologies within design projects.

Since the futures course is a new required course for 50+ third year undergraduate design students, we wanted to make sure to a) leverage what works from studio pedagogy (e.g., plenty of practice with guidance and feedback); b) manage exposure to content so students could engage more meaningfully with futures thinking and design; c) help students to apply the new concepts and methodologies to their design projects.

Here, we provide highlights of the course via four examples of the instructional activities connected to student learning experiences and outcomes: hopeful and fearful futures; alternative futures; connecting futures to real-world events; and experiential futures.

**Hopeful and fearful futures**

The preparatory course materials and in-class activities for “hopeful and fearful futures” were designed to a) connect students’ prior knowledge and experience to futures thinking; b) expose students to their own pre-conceptions about futures; c) contrast their personal views with those of
leaders in the Futures Studies field.

Elaborative Interrogation: Students were asked to explicitly link new concepts presented in the course to their own past experiences. For example, students were asked to list their hopes and fears through a series of sequenced activities (Figure 1). First, students considered their hopes and fears as two separate lists. Second, students considered their hopes and fears through two-time scales: short-term and long-term (Figure 2). Third, students were asked to consider their short- and long-term fears through the lens of STEEP forces (i.e., social, technological, economic, environmental, political). By connecting short-term personal hopes and fears to long-term STEEP forces, students could more easily identify larger societal issues.

Figure 1. Online module, pre-class work: “hopes and fears” sequenced activities to 1) list hopes and fears, 2) plot them on a short- and long-time horizon, 3) connect them to STEEP forces.

Self-Explanation: To promote discussion and self-explanation with peers, students aggregated the individual hopes and fears into word clouds and presented in class (Figure 3). As students explained their hopes and fears reasoning to each other, they identified and connected common themes, while also surfacing differences or diverging worldviews.
Distributed Practice: The sequence of weekly modules was designed to provide students with multiple exposures to new concepts and expert perspectives with distributed practice overtime. For example, on the topic of “Foresight” students noticed how futurist Alvin Toffler explored both the positive and negative aspects of futures. In the class discussion, we
compared the students’ word clouds (Figure 2) with the word cloud that students generated to represent Toffler’s perspectives presented in his 1999 “Big Thinkers” program for ZDTV\(^1\) (Figure 4). In contrast to the students’ focus on the future through their individual hopes/fears, Toffler focused on societal-level futures more holistically (e.g., social change, future shock). The distributed practice overtime gave students a foundation to compare their own thinking with the expert futurists and to better identify a broader spaces to explore.

![Figure 4. Online module pre-class work: Alvin Toffler's ZDTV "Big Thinkers" episode (left). Collective word cloud resulting from DF student key words extracted from the episode.](image)

Next students summarized the main points, from the *Futurestorming Series* for the 2016 World Futures Society conference, where prominent industry and academic futurists discuss these questions: a) What excites you most about the future? b) What can we do to address our anxiety about the future? By providing distributed practice (e.g., compare and contrast Alvin Toffler’s words in 1999 with a much younger generation of futurists in 2016), students would need to recall past content/concepts and connect that information with new concepts, thus helping with retention and further building of new knowledge (Figure 5).

Interleaved Practice: Rather than focus on a single method at a time, with interleaved practice, students were exposed to multiple futurists’ perspectives on foresight in the same work session. Foresight is a deliberate process of expanding awareness and understanding through futures scanning and the clarification of emerging situations. In these terms, it is evident that foresight expands the boundaries of perception forward in several ways. Foresight helps us to: (a) Assess possible consequences of our decisions and actions; (b) Anticipate problems before they occur; (c) Consider the present implications of future events; and, (d) Envision desired aspects of future societies. (Slaughter 1995). To help students distinguish the defining characteristics of foresight, they were asked to view and then compare and contrast the features of foresight discussed by

---

\(^1\) [http://www.virtuosochannel.com/2013/12/zdtv-big-thinkers-episode-2-alvin.html](http://www.virtuosochannel.com/2013/12/zdtv-big-thinkers-episode-2-alvin.html)

\(^2\) One student asked “what is the point of future studies and trying to shape desirable futures, when your personal nightmare becomes true?”
five futurists: Richard Slaughter, Jim Dator, Sohail Inayatullah, John Sweney, and Stuart Candy.

The activity of comparing and contrasting different definitions of foresight helped students identify common themes and differences, revealing how the field of futures studies has expanded and changed over time. In-class discussion provided a deeper dive into the foresight concept as students began to explain idiosyncrasies particular to each futurist. Students benefitted from the focused activity of finding distinguishing features across futurists.

Alternative Futures

One key lesson from the field of Future Studies, is that there is no singular future – there are multiple futures. To engage students experientially with the notion of multiple possible futures, we leveraged distributed practice and interleaving to help students critically engage with three different types of alternative futures scenarios: Royal Dutch Shell (Wack, 1985; Kahane, 2012), life@oneplanet (Luebkman, 2009), and four generic futures (Dator, 2009). In class, students described multiple possible majors and possible future careers within Dator’s four generic alternative worlds (i.e., continued growth, collapse, disciplined society, transformative society). By making the alternative pathways visible, tangible, and comparable, students were able to evaluate possible consequences of “difficult choices.”

Practice Testing: We embedded frequent low-stakes practice into the online course modules. After completing each pre-class online practice, students submitted open questions. At the beginning of each class period, we discussed students’ questions and misconceptions as needed.

In-class activities were designed for applying futures design concepts and for practicing with the new approaches/methods. For example, students were asked to develop and iteratively refine
scenarios for a three-generation persona family. As students were exposed to futurists work, over
time they developed a critical eye toward their own personas – explaining why their own were
“flat,” lacking the depth they found in the futurists’ perspectives. Thereby, students were
motivated to receive and use feedback from peers and guidance from the instructor to iterate and
refine their work.

Linking the real world to the classroom

On the first day of class, many students expressed fear at the prospect of a Trump presidency
(Figure 2). The unlikely 2016 election of Donald Trump caught many university students off
guard. The days following the election, some students questioned the validity of futures design
methods being taught. The US presidential election provided a rich context to meaningfully
eче́гі the course concepts and fueled a series of rich in-class discussions: What futures
signs did we miss that might have signaled the election outcomes? What were the STEEP forces
at work? How might we choose to address new challenges?

Experiential futures: bringing it all together

The final project for the class, “Experiential futures” (Candy, 2013) had multiple deliverables:
First, provide an audience with a first-hand experience of life in a possible future. Second, create
experiential futures with four levels: (a) setting: the kind of future world; (b) scenario: a specific
future history or state; (c) situation: one-to-one scale visible representation of time and place; and
(d) stuff: artifacts or instantiations. These four levels go from abstract to concrete (Candy &
Dunagan, 2016). Typically, design students were more comfortable within the realm of the
concrete and struggled to connect abstract ideas with concrete instances. Third, the final learning
objective was to connect the abstract level of futures scenarios with concrete artifacts and
tangible everyday experiences. In the assignment, students used: scenario writing, storyboarding,
designing artifacts and environments from plausible futures.

Students read an example of a professionally written futures scenario LEARN 2050!
(Wasserman, 2014). One limitation of written scenarios is that given the level of abstraction, the
audience usually struggles to imagine how it might feel like to live in such a future. In the final
project, students enacted a scene from an education future scenario set in year 2050. Students
created a five-minute skit to act out in the classroom so that the rest of the class could experience
what it might feel like to live in that specific future. Students used Dator’s second law of futures.
“Any successful statement about the future should at first appear to be ridiculous” but must be
balanced to remain plausible to the viewers. Student teams were to assume that parts of the
LEARN 2050 scenario had come to pass. They then asked: What problems disappeared or
significantly decreased? What new problems emerged or worsened? What surprising things
cesed to exist? Students explored artifacts, products, environments, or communications from the
future to help the audience experience the future scenario. Students embedded future artifacts in
a five-minute performance (Figure 6).

---

2 One student asked “what is the point of future studies and trying to shape desirable futures, when your personal nightmare
becomes true?”

3 The experiential futures assignment was adapted from Stuart Candy’s “Time Machine / Reverse Archeology” assignment.
Dexign Futures: Measures of student learning

In a post-course survey (n=43), to the open-ended question “What activities in the Dexign Futures course do you feel contributed the most to your learning?” On average, students listed 2.47 (SD 1.07) activities contributed most to their learning. The following percent of students selected these activities as contributing most: online course modules (61%), in-class discussions (41%), weekly reflections (29%), and group activities (22%). Students were also asked: “What, are concrete examples of how you applied what you learned in Dexign Futures class to projects you worked on outside of class (e.g., studio projects, independent projects, own life)?” We interpret student responses to mean they experienced the design futures toolkit most powerfully in their own lives and when exploring big design spaces.

Connecting futures to real-world events: Student reflections submitted during the week of the presidential election point to students’ learning and motivational challenges. In class, many students expressed a negative response to the Trump presidential election expressing loss of agency to influence their world and disillusionment with design futures. The instructor used the real-world event as context to connect to relevant course concepts (e.g., plight of the working class, income inequality). The just-in-time adaptation of the course addressed student motivational needs, provided a pathway for students to regain a sense of perspective and agency. Some students expressed appreciation for the opportunity to engage with current events.

4 “I definitely used this class to think about my own future quite a bit. For example, when we mapped out different ways our careers could go, and how they might play out in different societies, I thought about what would happen if I studied art or design, or if I worked for a firm or on my own practice. I realized in this class that I want to go to grad school to study textiles while making my futures wheel.”

5 “The most important thing I think one must do is think of multiple future scenarios - this formula of attacking a problem from different angles allows one to find the most appropriate solution to the problem.”

6 “I just wanted to write you a quick note to say that I really appreciated your sincerity and candor in class today. It's really obvious that you care about us and you want us to do good. Thank you for stopping to let us have these really important conversations, and for urging us to think more deeply, even when it isn't comfortable. One of my biggest fears is complacency--
Experiential futures: Student experiential assignment performances are a measure of student learning; and students’ self-reports are a qualitative measure of their learning experience. The instructor’s evaluation of the experiential futures projects revealed that students significantly iterated on previously written scenarios and storyboards to include much greater detail and depth to their final presentations. Students identified early in the course that their scenarios were “flat” and lacked depth as compared to experts’ scenarios. Over one fifth of students said that experiential futures project contributed most to their learning.7

**CASE 2: K-12 Pedagogy | Jobs in the Year 2050**

The primary purpose of the Design Learning Network (DLN) is to engage students and educators from all over the world in creative problem solving. The design learning process empowers creative problem-solvers with clear intentions via inquiry-guided design learning challenges. Students gather information, define problems, build new understandings, and show evidence of learning progress, while reflecting and assessing throughout (Figure 7). As educators, learners, creatives, decision-makers, and often community members – together we design experiences using high impact learning strategies. We learn how to learn, wonder why things are as they are, ask tough questions to figure out how to figure out, and make sense of an ever-changing 21st century world. Our challenges have explored a wide range of topics (e.g., looking into the future, the redesign of high school, and the plight of the honeybee).

We began opening the pipeline from K-12 to higher education in January 2014 with approximately one hundred students from Kansas City area schools. Inspired by the Dexitign Futures course, DLN facilitated an international future-foresight design learning challenge entitled, “Jobs in the Year 2050”. The Kansas City lead-teachers and students were guided by following critical question:

*Imagine the year 2050, how might the study of careers today, future, and past impact high school students as they prepare for college and jobs in the near future?*

Learners investigated future career opportunities by making sense of interconnections and interrelationships between job postings in the year 2014 to future job opportunities in the year 2050. The students investigated the learning needs of next generation creative problem-solvers as well as their own. Students proposed innovative job scenarios aimed at transforming current adverse environmental practices into balanced ecosystems by the year 2050 (Figure 8).

---

7 “I think we all need to be challenged more.”

“...made a big difference in my life, helping me understand the election results, my classmates, and more. The philosophical ideas are comforting and enjoyable to think about. More than all that, though, I want to thank you for the talk you began with on Friday about self-improvement. Living deliberately is something I realize I should spend more time on, and your speech helped me to that realization.”

“I think doing the skits in the last class helped me understand better because we had a chance to really talk with peers about future topics and got to share parts we don’t understand and parts we do. It was also helpful to learn what other people thought of a topic versus your ideas. The hands-on skit activity also was really fun and helped me experience what the future would be like.”

“I think the final presentation helped me a lot in that I could really get a sense of what is going on rather than just doing OLIs and read text.”

“I enjoyed learning more about education in 2050. I wish we had done more skits / bodystorming because it brought my understanding of futures to life. There was a wide spectrum of possible futures - it would be interesting if we could explore each unit through bodystorming / experiential futures.”

Figure 7. Overview of the Design Learning Process.

The Kansas City students collaborated with students from a middle school in Illinois, a high school in Massachusetts, as well the United Kingdom. DLN traveled to the University of Lincoln School of Art and Design where approximately 500 U.K. primary school students experienced the challenge firsthand at the School of Art and Design. Children ages 7-8 shared hands-on brainstorming sessions with a diverse group (e.g., high school and college students, faculty, professionals). Students shared real-time conversations via Skype with challenge participants back in the United States as well as universities in Nanjing, Beijing, Guangzhou, and Shanghai, China; and Girona, Spain; feedback was offered from a global perspective. The culminating event took place in Kansas City on March 1, 2014 (Figure 9).

Figure 9. Jobs in Year 2050 | Design Learning International Challenge, University of Lincoln, UK - February 2014.

Participants of this design learning challenge included a range of ages, alongside a widely diverse set of mindsets, some from a high-end school district, others from an inner-city district, some from completely different parts of the country – the lead-teacher sums it up nicely⁸.

---

⁸ Watching the design mentors work with students, the teachers learning alongside, and the students working quickly and brilliantly (and in some cases with completely new group members) to come up with even better solutions than they had brought to the table, not one person was concerned with the growing winter storm outside. As I have experienced repeatedly with the Design Learning Process, we witnessed total engagement and excitement from every participant. The final presentations gave each student the chance to be heard, develop confidence, and prove to themselves and the entire
Integrated aspects of learning science:

Elaborative Interrogation: to make meaning, learners first studied the type of jobs available in 2014 – before defining what future jobs might require in the year 2050.

Self-Explanation: for greater comprehension, learners explored their own learning needs as young creative problem-solvers – alongside likely requirements of the next generation.

Distributed Practice: for longer retention to take place, challenge participants grew their understanding of the problem set over 2-months’ time – with multiple opportunities to check-in with their teammates as well as lead-teachers and creatives.

Interleaved Practice: for deeper understanding of new concepts, learners developed their solutions by practicing visualizations, creation of mockups, etc. during the culminating event.

Practice Testing: for long-term memory retrieval, learners engaged in iterative formative assessments to check for understanding prior to generating their plan of action.

In summary, creating effective learning pathways between primary and secondary students with university design schools on a global scale is a compelling concept. Lessons learned: we now know primary students are able visualize their ideas and could have benefited from showing their new understandings in 3-dimensional form similar to the secondary students.

Case 2: K-12 Pedagogy | Insightful Experiences, Monumental Understandings

The second test of adapting our university-level design materials within the K-12 context took place in December 2016 with over 150 low socioeconomic status (SES) high school students. The Insightful Experiences, Monumental Understandings Design Learning Challenge invited learners to become aware of the powerful concept of Habits of Mind – which habits they carried out with confidence, which required more practice (Figure 10). At the conclusion, students explored their hopes and fears in respect to their personal goals and related Habits of Mind, a slightly modified version of the university-level Design Futures course (Figure 1).

Garfield Gini-Newman and Roland Case of the Critical Thinking Consortium describe students who practice Habits of Mind as “motivated thinkers are inquisitive, consultative, open-minded, fair-minded, tolerant of ambiguity, self-reflective, and attentive to detail. An individual’s attitudes – or habits of mind – are key constituents of good thinking. People who are closed to new ideas or inflexible in their thinking are seriously impaired in their ability to arrive at justifiable resolutions of issues. Open-mindedness is but one of an array of habits of mind needed by thinkers. Some individuals tend to leap rashly to conclusions. Here underlies another crucial mental habit of a good thinker, the inclination to deliberate – to think before acting. Successful thinking is significantly (but by no means exclusively) a matter of attitude.”

audience that their ideas were important. As I watched the final presentations, and then listened to the design mentors validate each group’s strengths before the whole audience, I realized that all of us had crossed many bridges (and even an ocean) to make this experience possible. It was a truly amazing experience, and I look forward to building even more bridges towards KC2015. – KC2014 Lead-Teacher.
Participants began the challenge by identifying a monumental person in their life, someone who had served as a significant source of inspiration. Students then selected an insightful experience, an interaction shared with their inspirational person that had monumental impact on their own Habits of Mind. Students mapped their reflection using the following prompts: What is your person saying? What is your person doing? What is your person thinking? What is your person feeling?

Prior to the Monumental Understandings Gallery Walk, students empathized with their viewers by previewing what they might say, do, think, and feel. In addition, students created sketches and representational mockups of their Insightful Experience (Figure 11). Similar to the Design Futures students’ experiences, these high school students concluded with a personal reflection regarding their short-term and long-term Hopes and Fears. Note, the word clouds in Figure 12 indicate these low SES high school students were able to clearly articulate what they felt in their hearts; knew in their mind – not dissimilar to high SES students. Post-challenge comments by the lead-teachers suggest future-learning explorations of this kind would be of high value.

**Integrated Aspects of Learning Science**

Elaborative Interrogation: to make meaning, learners first recognized what they knew about themselves and their monumental person – before immersing into the unknown, what viewers might say, do, think, or feel.

Self-Explanation: for greater comprehension, learners built on the empathy mapping exercise to select which insightful experience to share – prior to representing the interaction in sketch and 3-dimensional forms.

---

9 I have never seen this level of engagement and focus from my students in such a short period of time. Today’s experience has caused me to rethink my entire approach to teaching. – High School English Teacher.

I was taken aback today, watching my special needs students – it was like they were a different person, showing initiative, collaborating with others, and far more articulate than they normally are. One student in particular stands out; she rarely speaks in class much less directly with me. Throughout the session, she was on task and jumping in like the rest! – High School Art Teacher.
Interleaved Practice: as evidence of deeper understandings, learners used the Hopes and Fears exercise to shift their focus to their own Habits of Mind – to articulate short- and long-term actions, ways in which to accomplish their goals, as well as insights into potential barriers.

In summary, the shifts in perspectives embedded in this learning experience challenged learners to get outside themselves and dig deep into levels of awareness, the craft of creating representations, and gaining insights by sharing with others. Lessons learned: however rarely spoken or heard, we cannot underestimate learners’ need to articulate what they are thinking and feeling. We need to: (a) support our learners in productive articulation; (b) promote active listening, and (c) nurture the learner’s capacity to learn, think, and articulate.
Discussion and future work

The Dexign Futures course sought to address three challenges observed in previous courses where students aimed to combine futures thinking with design thinking (Wasserman & Scupelli, 2013; Scupelli, 2014; Scupelli & Wasserman, 2014; Wasserman, Scupelli, & Brooks 2015ab; Scupelli, Wasserman & Brooks, 2016ab). First, an advanced studio course that requires a completely new type of design method overwhelms students. Second, in traditional studio and seminar courses students struggled to manage the breadth of information necessary to critically engage with futures thinking. Students focused on a single future scenario superficially and were unable to go beyond personal experiences and biases. Third, students were unable to interpret futures signs, forces of change, and benchmark goals for desirable futures. To help overcome these challenges, we created the Dexign Futures course as a flipped learning and active classroom experience to connect to and scale studio pedagogy from fifteen students to fifty.

We found that the flipped classroom pedagogy and in particular the use of the online homework with immediate feedback and the opportunity to discuss open questions in class supported student learning at scale. While the online modules worked to expose students to concepts, students were still not quite ready to apply those in class as the next step. Additional mini lectures were inserted when students needed to see an expert link the concepts to an application. With this adjustment, students also benefitted from the resulting group-level discussions. The additional in-class lectures and class discussion helped students bridge the chasm between online
homework and in-class activities but reduced class time to complete in-class activities. As such, students finished the in-class activities as homework. For next year, we are redesigning the in-class activities to fit into shorter timeslots.

We implemented weekly reflection questions to help students consider how they might apply *Design Futures* methods into their studio projects. We are exploring with other faculty how to help students apply these futures thinking methods in their design courses. To empower faculty in other courses to help students apply new methods, we are discussing how such methods might fit into their courses. Likewise, the high-school teachers commented on how engaged some of their lower performing students seemed to be in the workshop, but wondered how they might implement such pedagogy in their own classrooms.

The word clouds for the hopes and fears exercise done by the DF course students (Case 1 Figure 3) and the DLN challenge participants cover similar topics concerning short-term and long-term futures (Case 2 Figure 12). Future work for DLN includes adding exercises to help the K-12 students broaden their perspective on shaping their futures by transferring newly acquired understandings into other contexts.

In the Habits of Mind challenge, the Monumental Person exercise had high-school students reflecting on positive influences in their lives. The goal of the activity was for the students to reflect on the habits of mind that helped such people respond to difficult situations. In future work, we would like to embed the Monumental Person exercise into the university DF course to scaffold the connection between habits of mind, personal character, and role models.

The students in the Jobs in the Year 2050 Design Challenge proposed innovative job scenarios to explore the connections between current job postings and future jobs. Similarly, the DF university students explored personal alternative careers in four alternative worlds (i.e., continued growth, collapse, disciplined society, transformative society). We posit that one desirable outcome of both exercises was that some students began to envision their own future career in a more optimistic way, feeling agency and hope to achieve desirable futures.

Encouraged by this first pilot study between the DF course authors and the DLN in K-12, we pursue three main areas for future work: Improve the DF course modules; Explore alternative timescales for DF and DLN activities; and Develop common assessment measures to study student learning. First, we plan to implement three changes to the DF course modules: implement adaptive feedback, add more expert worked examples to support students in how to apply future thinking to design type problems, and revise the in-class activities to bridge the gap between thinking and doing in the classroom (Figure 13).

To allow for more interactive in-class activities, the course is now taught in a flat design classroom with large whiteboards and furniture on wheels. Second, the course duration differences between a semester long course and shorter K-12 Design Challenges encourage us to explore shorter modules. Third, we would like to develop common measures to assess learning in the K-12 and university settings. We seek to study student learning and retention over time.
We would like to thank for the support of the: Neirenberg Family for Arnold Wasserman’s endowed visiting professorship in 2013; the Wimmer Family Foundation for Peter Scupelli’s 2013 Wimmer Faculty Fellowship; and the Carnegie Mellon University Eberly Center for Teaching Excellence and Innovation for continued encouragement and support. We would like to thank the Revere Public Schools for their generous support of the Design Learning Network.

From Software Engineering to Information Design

Yvette Shen, The Ohio State University, Columbus, Ohio, USA
shen.1049@osu.edu

Abstract

Most academic methodologies are developed from a prescribed methodological process that is limited to a specific area of study. However, the disciplinary landscape in which the knowledge is established is being rapidly reconfigured. Given the vast varieties of practices and knowledge base required from information designers, it is even more crucial for them to look outside of the traditional visual design fields and seek diversities for better research and creation methods.

The two disciplines, software engineering and information design, are often perceived as one provides technical solutions to the other. This essay intends to move beyond the common perception, and identify relevant issues in software engineering design that resonate with the information design process. The issues include the multi-component planning approach; the human-oriented agile method; design concepts such as abstraction, decomposition, component modularity, hierarchical relationship, and extensibility. The perspectives from software engineering design and information design is examined through units of analysis, terminology explanations, and forms of communications. The collective design methods and principles provide a systematic framework to the methodological thinking in information design. The discussion serves the purpose of encouraging more conceptual-based conversations between information design and other disciplines, especially in the fields of science and technology.

Keywords: information design process; information design principles; software engineering design; cross-disciplinary design methodology; design and technology

Information is a very broad term. It can be data, knowledge, instruction, location, fact, story, sensory experiences, etc. Information design has always been practiced and systemized by different areas of professions: science, journalism, business, geography, humanity, engineering, architecture, and design. Finding a single comprehensive definition for the term “information design” is almost impossible. While different practitioners may have distinct interests for the purpose of information design, their core objectives and concerns are similar: to present information in a clear and effective manner. Making attractive and accurate information design requires more than a computer drafting software or cut-and-paste template. The aesthetic concerns are as important as how the narrative is clearly and efficiently portrayed. Successful information design creates visual solutions that help to define, explain, or order contents, simplify complexity, relate the seemly unrelated, discover what has been hidden, and create insights (Cairo, 2013).

Software engineering is the development of software in a systematic method. The design process helps the software engineers turn specifications into a working software system. It usually includes architectural views, as well as detailed component and algorithm implementation issues (Laplante, 2007). The design aspects in software engineering often
reflect the goals the software is trying to achieve. A well-designed and implemented software system requires creativity, accuracy, and a human-centered approach.

The two disciplines – software engineering and information design – are already highly related to each other as one often supplies technical solutions to the other. Software engineers are often responsible for bringing visual designs to life. A successful information design is where user needs and technical feasibility overlap to create efficient and effective communication. Information content is managed, analyzed, and filtered by software programs. The visual elements being used to depict the information are also created, processed, and arranged by software programs.

Most academic methodologies are developed from a prescribed methodological process that is limited to a specific area of study. The disciplinary landscape in which knowledge is established is being rapidly reconfigured, however. Given the vast varieties of practices and knowledge-bases required for information designers, it is even more crucial for them to look outside of the traditional visual design fields to seek diversity that will lead to more effective research and creation methods.

**Literature Review**

Design is often referred to as “problem solving”. A well-known creative strategy for problem solving in design practice and beyond is design thinking – an iterative process of empathizing, defining, ideation, prototyping, and testing. It takes a human-centered approach to bridge the designers’ toolkit and the target audiences and users’ needs (Brown). While virtually all forms of design are human-centered, information design focuses on the accurate understanding of a specific knowledge set and the unique needs of the end user receiving clear and accessible communication with complex problems. Complex problems usually are made up of many interrelated elements (Hansen, 1999, p.193). They are situated in specific contexts and their parts interact continuously at many levels and across shifting boundaries. In order to convey or even resolve the problem with visual forms, it takes a flexible process that can help reveal relationships among parts.

Many information designers follow an established design method and creative process that usually associates with other design tracks, such as the Goal-Directed Design approach developed by Cooper consultancy for human-centered products and service designs that focus on achieving a series of goals. The Goal-Directed Design process involves project planning, research, modeling, requirements definition, framework definition, detailed design, and implementation support (Goodwin, 2009). Another design method- Atomic design- is a rising design methodology in the field of interface system design that advocates for creating design systems with the big picture in mind. This method breaks down user interfaces (responsive in most cases) into their basic components so that they can be reused throughout the system. It is composed of five distinct stages: atoms, molecules organism, templates, and pages (Frost, 2016).

Although information design shares many foundational basics with other design areas, it has its
own unique characteristics. It is a broad and exploratory discipline that encourages research and analytical thinking. It requires a galaxy of disparate tactics being bound together to create successful information solutions. Given the complicated information problems that people will face increasingly in the future, the need for information design could not be more profound. The sheer volume of information and the increasing cost of time demand a more intuitive framework to ensure effective communication. When modern design becomes increasingly relevant to technology, how to employ graphic language to analyze bits of information from particular points of view also demands diverged research methods and processes.

Information design rests on a large range of research foundations: psychology, communication studies, sociology, linguistics, statistics, computer science, cognition science, and various design focus areas (Horn, 199, p. 22). Digital technology has always had inextricable connections with visual communication. The exponential growth in one area leads to increased production of the other. Historically, designers have responded to technological changes by updating their tools and output media. Since information design demands a very analytical mindset to understand and present data and information, it seems natural to make a conceptual connection between information design and disciplines in science and technology.

There has been a constant debate about whether designers need to learn programming in today’s technology-driven world (Stinson, 2017). Although software development increasingly infuses how design is planned, produced and consumed, designing and programming are often perceived as two areas pointing to opposite directions. However, when one investigates closely, the two fields of study may share more in common than what is presumed. In the field of software engineering, the word “design” often occurs. Software design means the process of transforming user requirements into some suitable form. It is the process of implementing software solutions to solve problems. Software design often relies on suitable design patterns. There are design models and design principles that should be followed during the process (Pressman, 2014). There is a definite parallel between the perspectives from design and software engineering. Software engineering seems to have an even stronger connection with information design because both require precision, innovation, creativity, organization, and rigorous logic.

The relevance between the two areas of study may be beyond the simple perception of one being the “front-end” and the other as the “back-end”. The following sections will examine the detailed design process, design principles, and some key design concepts from software engineering, and attempt to apply the framework to the methodological thinking in information design.

**Research Methods**

Any discipline has an epistemic dimension and a social dimension. The epistemic side uses specific analytic tools, concepts, and methods. From the social side, a discipline also entails related “subsets” that practice its techniques. Interdisciplinary work builds on disciplinary perspectives as described above and combines them to achieve a result that is unobtainable through a single disciplinary means (Miller, 2004). Thus, the disciplines are not simply juxtaposed, but deeply intertwined. Findings in one domain illuminate the other. In what follows, the perspectives from software engineering design and information design will be examined through units of analysis, terminology explanations, and forms of communications.
Some concepts and methodologies may be more obviously identified as mutually shared than others. However, a different viewpoint can always benefit the development of one discipline, especially a field like information design that has its roots in a variety of areas. The cross-disciplinary efforts also rely on recognizing the differences and exploring new potentials for how different areas of study can sustain each other.

Design Process

In software engineering, the design process starts from defining the problem and moves toward the solution of the problem. The process usually requires iterations between macro- and micro-level perspectives (Schmidt, 2003).

The macroscopic steps involve decomposing the required specification into various components; identifying various components and how components interact with each other; as well as a more detailed description of the components that allow them to be constructed.

The multi-component approach to product design and development has evolved since the industrial revolution. The approach can be naturally tailored for an information design planning process (consider Ikea furniture and their corresponding assembly manuals). Information design relies on using visual vocabulary to convey complex sets of facts or data. An effective strategy to analyze a complex problem is to break down big problems into smaller pieces that can be addressed more easily. The smaller pieces are not independent entities, they relate to each other in obvious or not-so-obvious ways. Therefore, the correlation of different components is as important as the contents of the individual piece. This multi-component approach is one of the key foundations in software engineering design, and the concept is also reflected in software design principles.

The microscopic level in software engineering design is an iterative process that involves navigating through multi-level decision points based on the specifications, hierarchy, comprehension, and implementation. The Agile Process, a methodology that was first coined in 2001, has been a growing movement in the software development process that is human-oriented and adaptive rather than a traditional process-oriented and sequential approach. The general idea of Agile means to divide time into iterative and incremental cycles known as “sprints” to address a process need (Figure 1). The method stresses customer satisfaction (early and continuous customer and stakeholder involvement). It advocates adaptive planning (sustainable design that can quickly response to changes and continuous development), and it utilizes prototyping during the design process by present working software to clients during the design milestones rather than comprehensive documentation. It also promotes the creation of a collaborative work environment such as co-location and pair programming (James, 2015).

Test/Review
The agile methodology has already been widely adapted into the interactive design and user experience design fields. When elements of novelty are involved, such as evolving requirements, changing priorities, and flexible deliverables, the Agile approach seems like a natural fit. The cross-functional team environment also facilitates transparency and allows issues to be identified early. Some essential design principles in software engineering-- many derived from the agile philosophies-- can be valuable for mapping the features, structure, and information flows of an information design system.

Design Principles

Some of the key design principles in software engineering include: abstraction, decomposition, component modularity, hierarchical relationship, and extensibility. The following sections will explain how these principles may as well be applied to the building blocks of information design.

Abstraction

In software engineering design abstraction manages complexity by emphasizing essential characteristics and suppressing implementation details. It allows postponement of certain design decisions that occur at various levels of analysis. In information design, a designer can be asked to be a narrator or an editor as well as a visual designer. The act of clarification and determination goes beyond the scope of making aesthetic choices. The cycle of turning data into useful information is a crafty process. Different methods of organizing can create different vantage points, and how designers approach data, understand, and perceive information affects how the information is communicated to audiences. Although a wide range of sources is essential for initial information gathering and analysis, focusing on too many details at the earlier stage of design will create unnecessary distractions for information filtering. The selection of certain information will always carry a certain bias. The designer’s perception will also be reflected on the design decisions. Therefore, how information is selected and organized has a broad impact on what will ultimately be communicated.
Since visual decisions are better made when the analysis of the problem becomes thorough, the principle of *abstraction* can be an effective strategy to filter and organize information. It can be applied to judge whether the collected information is relevant, useful, and explicit to the content, visual form and composition. The principle suggests starting with the
simplified solution – the essential characteristics of complex information and ignore the remainders. Then progressively move back-and-forth between different levels of abstraction from individual modules to the entire system. It is from this point that patterns may be observed and new leads for further investigation arise (Figure 2). The goal is not only to determine what information is necessary or where it should be, but to establish an underlying design logic. A well-defined problem is the foundation of successful visual communication.

![Diagram of high and low abstraction]

Figure 2: High abstraction for the broad view of the problem.

**Decomposition**

Decomposition uses the “divide and conquer” concept to dissect large problems into smaller problems. The components within the large piece is determined using a design paradigm, such as functional, structured, object-oriented, etc. The descriptions concern not only the individual component, but also the components’ interactions.

Most information design problems can be viewed as an entangled network that entails cause and effect, facts and comparisons, data and analysis. The essence of visually presenting the system in a clear and effective way lies in a shift of mind: being able to see interrelationships rather than the linear chains, and to recognize processes of change rather than snapshots (Hansen,
To dissect a complex problem into smaller building blocks can help designers better understand the overall objective of the information conveyed.

Decomposition can be helpful for information designers to understand the problem as well as to find the right visual form to depict the problem. One of the biggest advantages of using visual representations over text is pattern detection. Designers can first look for visual components that already exist for the functionality they wish to achieve, because familiarity can benefit the perception and understanding of information. For example, a timeline is a proven visual form to show the passage of time—a series of steps reflecting change. However, sometimes simply using a line along which to place marks is not adequate to depict the given information. Some other visual forms, many derived from a basic timeline such as Gantt Chart or Swim Lanes, allow more layers of information. For example, the visual form of a Gantt Chart can be deconstructed into three components: time, tasks, and how different tasks relate to each other and within the same given time period (Figure 3).

Component modularity

A modular system in software engineering is one that’s structured into identifiable abstractions called components. A component can be a software entity that represents an abstraction, or it can be a unit of code that encapsulates data or has identifiable boundaries. It is self-contained and provides a distinct functionality (Pressman, 2014). A component-based application is assembled by connecting the components together. Cohesion is one of the key concepts that are stressed in a component-based software system. It is the degree to which the components belong together within a module. It aims to group together related functionality that contributes to a single lucid task. The goal for a software engineer is to achieve high cohesion so that each component has a well-defined yet distinctive function and the system performs better when the components have a stronger relationship to one another.

The process of information design is a non-linear and recurrent matrix system. The cycle that involves defining, research, analyzing, visualizing, and evaluation are iterative, but also flexible and connected. If the concept of component modularity and cohesion were adopted in relation to the information design process, then the modules can be categorized as semantic or syntactic. The components within these two types of modules will be a number of variables that need to be addressed in the network of concerns. The semantic components include, but are not limited to,
objective, content, context, audience, and reference. The syntactic components may include line, shape, form, color, texture, space, type, and medium. The connection between the variables forms a systematic approach that results in a framework of the semantic components to be expressed through a particular set of syntactic components (Figure 4). The individual component has its own purpose, yet they rely on each other to function as a unit. A modification of one component may affect the rest. For example, to visually explain the sales figures by month, a designer can place a simple bar graph on a time-quantity-based coordinate system. The information of each month’s sales amount as well as their comparisons can also be well represented. But if a designer fine-tunes the diagram by adding another syntactic component to it, such as applying contrasting colors to the tallest and the shortest bars, then the visual diagram represents a different objective: to identify the best and worst sales month (Figure 5).

Figure 4: Semantic components and syntactic components in information design.

Figure 5: Changing one syntactic component affects the syntactic module.

One benefit of a component-based approach in software design is its reusability. The idea of “reusable” components can be applied to design knowledge rather than the reuse of artifacts produced in prior design efforts. Then a strategy pattern will be the record of how a particular
recurring problem was solved in the past. The design strategy is general enough to be adapted and reused in a way that matches a similar situation. The best visual solution can be found by recognizing and recording different levels of components that are proven to be successful.

*Hierarchical Relationship*

Hierarchy organizes information by measure (scale of size, scale of weight, etc.) or by perceived importance (rank, stature, etc.). Being able to identify the hierarchical relationship depends on a clear understanding of context. A class diagram in the Unified Modeling Language (UML) is usually used to describe the structure of the software system. It serves as a transition from “what” the system shall do to “how” the system will do it. It resembles a flowchart in which the classes and their relationships are identified. The relationship that defines the hierarchy including “uses”, “is-composed-of”, “is-a”, and “has-a” (Schmidt, 2003).

The systemization of the content transforms information into information design. Just like software engineering design, it is imperative to examine hierarchical relationship throughout the process. All information needs to be understood in relation to itself within a framework of comparisons and in a wider context. Richard Saul Wurman, a professor of architecture, suggests five ways to organize everything – location, alphabet, time, category, and hierarchy – also known as the LATCH model (Shedroff, 1999, p. 275). Besides information hierarchy, the concept of “hierarchical relationship” may also be adopted to visual hierarchy – using aesthetics to implement the order of information. The two are closely related. The visual hierarchy not only depends on information hierarchy, but the former is also constrained by the latter.

How should you identify hierarchy in information design? A writing organizing structure used by journalists has been suggested to apply to information design contents. The framework is called “*the inverted pyramid*” - a journalistic writing style that places the most important information at the beginning of the story, and supporting details are included in order of importance (Figure 6).

The most important information is a lead that usually answers questions about who, what, when, where, why, and how. This should be followed by supportive information, and concluded with technical details. This structure allows readers to gain a quick yet solid understanding of the most relevant facts (O’Grady, 2008, p.84). Readers’ consumption of an information design project usually involves two steps: first, a quick overview; and second, a more detailed look at the content. During the first step, the reader searches for the core concept or message. Based on the result, he or she will decide whether to take the second step. Therefore, strong contrasting visual elements such as color, size or spatial arrangement are fitting to catch readers’ attention from the beginning. As readers proceed through levels of information, they process how the content supports the main message. Then levels of hierarchy can be reflected in the typography, alignment, or color-coding, while maintaining a rhythmic visual consistency (Figure 7).
Extensibility

Extensibility is a software system’s ability to take future growth into consideration. When new functionalities or requirements are extended, the existing structure and data flow are minimally or not affected. An extensible design in software engineering means the design is open-ended, and it solves a class of problems rather than a single instance. The constant evolution of new ideas and new technology demand more flexible designs.

If the design project is meant to be consumed via various media outlets, then the visual and performance quality shall not be affected by technological constrains. If the design project is integrated with a dynamic data system, then extensibility also becomes an important aspect of planning. The visual framework shall demonstrate the same capacity and behavior regardless of how the data progresses. Besides technology–related concerns, the idea of extensibility can also be adopted in relation to the conceptual development during the design process. Some may identify the objective of information design as to design a product or visual representation that delivers information. The objective, however, should be to achieve a more general design goal (Passini, 1999). Receiving information is only the beginning. What users or viewers can do or gain with the given information is more important. The objective of designing
a way-finding system for an airport is not finding the perfect icon and type, but to assist people to move around quickly and effortlessly (and accurately). Therefore, extensibility is also about seeking sustainable design solutions. When new variables or components need to be added to an established information system, the design can still satisfy its broad-view goal without major structural changes.

**Conclusion**

This essay identifies some issues in software engineering design that resonate with information design. The issues include the multi-component planning approach, the human-oriented agile method, and software design principles such as abstraction, decomposition, component modularity, hierarchical relationship, and extensibility.

The *multi-component planning* approach suggests breaking down big and complex information problems into interrelated pieces. Designers can build a mental model of the smaller components so the connections between the pieces can be perceived from the big picture. The *agile method* emphasizes the team work environment, adaptive planning, and utilizing prototyping during various stages of the design process. The principle of *Abstraction* helps information designers to evaluate the relevance and usefulness of the collected information.

*Decomposition* can be a strategy for information designers to create the appropriate visual forms by breaking down the required functionality and building upon existing visual representations. Inspired by the *component modularity* principle, a process model that is composed of a semantic module and syntactic module is proposed. The dynamic relationship between the components inside the two modules constructs the framework that connects the information and the corresponding visual forms. Establishing a logical *hierarchical relationship* shall be applied to both information contents and related visual elements. The value of *extensibility* lies in the functionality and sustainability of the design, as well as helping designers keep the design goal in their minds – how the design will inform and help people.

**Discussion**

Interdisciplinary collaborations are valued now more than ever. Assessing the leverage afforded by a different perspective demands a meta-disciplinary form of awareness (Miller, 2004). Considering and understanding a different disciplinary perspective can raise questions and propose a hypothesis that has been missing. Some perspective may provide explanatory leverage, while others may offer pragmatic leverage. This essay intends to encourage more conceptual-based conversations between information design and other disciplines, especially in the field of science and technology.

Design is a fundamentally creative activity. Once the barriers of communication are overcome, it may become apparent that many concepts and ideas in design-related domains share more similarities than differences. Even though one design system is built with visual elements and the other is built with machine languages, design procedures and the principles have more to share than the traditional “dividing-up-tasks” approach. There is a great potential for synthesizing knowledge and thinking creatively across perspectives. A systematic integration of different design-related disciplines may create new theories, methods, and concepts that can dissolve borders between disciplinary domains.

**Yvette Shen**

Yvette Shen is a visual communication designer and educator. She currently works as an Assistant Professor of Visual Communication Design at the Department of Design, The Ohio State University. She worked as a professional web, interactive, and print designer before she joined the academia. Her current research lies in the domain of information and data visualization, reflecting both the development of her own creative work and the evolvement of visual communication design pedagogical methods. Her creative works and research essays have been recognized and awarded by various design organizations and publications. Her work has also been exhibited worldwide.
Taxonomy of Interactions and the Design of the Airport Passenger Screening Process

Abstract

This paper presents a case study analysing the interactions of nine security officers during the mandatory passenger screening process at an Australian international Airport. Eye-tracking glasses were used to observe the visual, physical and verbal interactions of security officers while they performed the x-ray task. Stationary video recording devices were used to record physical and verbal interactions performed by security officers during the load, search and metal detector tasks. Six taxonomic groups were developed that define the different types of interactions performed by security officers during each task. Each taxonomic group is comprised of several discrete interactions specific to each of the tasks observed. Through analysing the composition of interactions and the relationships between interactions in different tasks, this paper highlights the prominence of interactions that security officers perform with passengers and their belongings. These interactions play an important role in the first and last stages of the passenger screening process, as well as influence the functioning of the overall passenger screening process. Due to this, they have substantial effect on passenger experience, throughput efficiency and security efficacy. In response to these findings, we draw from emerging security technologies and persuasive design principles to present potential design solutions for optimising the passenger screening process. These are presented in the context of a preliminary framework with which to inform the design of current and future passenger screening processes.

Keywords: Activity-centred design, airport security process, interactions, taxonomy.

Airport security is a complex system comprised of several layers that work concurrently to protect users of the airport and its services. The mode of these layers varies. Some operate in the background, such as intelligence and video surveillance. Others, such as the passenger screening process and customs, are clearly visible (Johnstone, 2015). Perhaps the most conspicuous of these, and the focus of this paper, is the passenger screening process. As a major processing point in the airport, the passenger screening process requires considerable human and financial resources. It is a mandatory process in which passengers must obediently participate in the examination of their person and belongings by trained security officers who operate various screening technologies (Graves et al., 2011). As well as being highly conspicuous, the passenger screening process is considered to be the most scrutinised of the different layers of security in the airport (Johnstone, 2015).

The scrutiny placed on the security screening checkpoint has largely been due to poor test results and significant security breaches. Tests conducted by the Transport Security
Administration (TSA) have shown that an alarmingly high number of threats pass through the security screening checkpoint undetected. The TSA has reported that security screeners at Los Angeles and Chicago airports missed over 60% of fake bombs in 2006 (Johnstone, 2015). This, along with high profile security breaches, such as the December 2009 attempted bombing of Northwest Flight 253, has made the security screening process a continual focus of investigation (Champion, 2012; Johnstone, 2015). Recognising these imperfections, and acknowledging the evolution of what constitutes a threat, airports implement a strategy of additional screening measures and the deployment of increasingly sophisticated technologies (Graves, et al., 2011). While these are seen to be necessary implementations to enhance security, they also add to the complexity of the passenger screening process and the tasks performed by security personnel.

Further to security efficacy, the passenger screening process must also balance other functions. Airports place strict economic pressures on airport security as the airport must demonstrate a certain efficiency and facilitate passenger throughput to remain viable (Salter, 2007). Passenger throughput, of course, must be balanced with adequate security efficacy to ensure the safety of airport passengers and staff, and protect the values of broader society. Failure of either security or economic functions is viewed as unacceptable. Adding to these two functions, the notion of passenger experience in the passenger screening process has gained traction in recent years. This has come in the form of the ‘security as a service model’ which was proposed by the International Air Transportation Association (IATA) and Aviation Council International’s (ACI) vision of ‘Smart Security’ (2016).

While recognising passenger experience as an important aspect of security, Smart Security aims to address equally the functions of security, economic efficiency and passenger experience. It proposes to do this by better organising the technical and human aspects in the design of the passenger screening process. Some key elements of this design strategy are remote x-ray screening, automated baggage transport and tracking, advanced screening technology and the provision of adequate spaces for preparation and repack of belongings (2016). The addition of passenger experience as a key consideration of airport security screening is consistent with the design strategy implemented in other airport services, such as retail, entertainment, and connectivity. In comparison, Airport security is a service that has remained relatively unchanged since the 1970s (Australian Government, 2009).

Given the competing functions of the security checkpoint, this paper analyses the tasks and interactions performed by security officers in the mandatory passenger screening process. In doing so, it contributes to the development of a taxonomy of interactions in the security screening context. It is expected that categorising and quantifying the interactions performed by security officers can provide a better understanding of discrete task functions and their role in the larger process. Short term, this understanding looks to inform design solutions for immediate implementation in the security screening process. Long term, there is the potential to assist planning and implementation of broader scale changes to the design of security processes to best service the functions of the passenger screening process.

**Method**

Observations were conducted at a security screening checkpoint at an Australian International Airport. The focus of observations were the interactions performed by security officers during the four tasks in the mandatory passenger screening process: (i) X-ray; (ii) Load; (iii) Metal Detector; and, (iv) Search (Figure 1).
Each of these tasks require various interactions to be performed with technology, staff, passengers, and passengers’ belongings. To capture detail of these interactions, Tobii eye-tracking glasses and stationary video and audio recording devices were used. In addition to the four mandatory screening tasks reported in this paper, security officers also perform the tasks of explosives trace detection (ETD) and body scan (Figure 1). These tasks were not mandatory for passengers at the airport in which observations were conducted, and due to the scope of this paper, are not reported.
A total of nine security officers were observed while they performed each of the tasks in the mandatory screening process. Eight participants were male and one was female. The age of participants ranged from 20 years to 58 years old. Participants were recruited on the day of observations. They were first approached by the manager on duty, and upon agreeing to participate, were introduced to the researcher. Participants were then briefed on the observation procedure and asked to sign a consent form. Before signing the consent form, participants were informed that they could withdraw at any time and their decision not to participate would not result in any penalty.

**Procedure**

During normal task operations, security officers rotate through each of the tasks (Figure 1) at 20-minute intervals. Observations of security officers were conducted within this normal rotation policy. The order of tasks observed was (i) X-ray; (ii) Load; (iii) Metal Detector; and, (iv) Search. Prior to commencing an observation, Tobii eye-tracking glasses were calibrated to the participant. This involved a short eye-tracking task (approximately 2-3 minutes) and was conducted in a private location. Calibration is required for pupil tracking rate and tracking accuracy on a 5-point scale. Any participant unable to register a score on either of these scales was not calibrated and not able to participate in the study. All nine participants were successfully calibrated.

Participants were escorted to the security screening lane after being successfully calibrated. Observations of the X-ray task began at the first available rotation. Tobii eye-tracking glasses were fitted to participants and then set to record. Just prior to beginning the X-ray task, participants were reminded to deliver concurrent verbal protocol. This required that participants ‘think-aloud’ (Cooke, 1994; Van Someren, Barnard, & Sandberg, 1994), providing verbal comment on their interactions and processes. This assisted with interpreting the type and purpose of the interactions being performed. While participants were performing the X-ray task, Tobii eye-tracking glasses collected video from their visual field, eye movement data, and audio data of concurrent verbal protocols (Figure 2). At the completion of the 20-minute rotation, Tobii eye-tracking glasses were removed from participants and the recording was stopped. Participants then moved to the Load task.

Load, along with Metal Detector and Search are dynamic tasks. They often require movement between locations in the security checkpoint, and different interactions to be performed at the respective locations. GoPro Session video recorders with suction mounts were used to
capture these interactions. Upon rotating between each of these tasks, the video recorders were positioned at the location and set to record (Table 1).

Table 1. GoPro Session video recorder location and interaction focus

Video recorders were positioned to capture the primary interactions that occurred with technology, luggage, passengers and other staff. Depending on the task, either one or two video recorders were used. Two were used during the Search task to capture interactions that occurred between multiple locations. Only one was required for the Metal Detector and Load tasks as the security officers performed interactions from a stationary position. Video recorders were positioned so they did not impede the interactions of the security officer or the passengers and their belongings as they moved through the security checkpoint. When the participant completed a task (20 minutes), the video recorders were moved to the next task location. Data collection was complete when participants performed each of the four tasks within the mandatory passenger screening process.

Data analysis and taxonomic groups
Data collected from observations of each task were coded in The Observer XT 13.0 (Noldus, 2016) behavioural analysis software. Coding schemes were developed using a process of open coding (Benaquisto, 2008). As video data were reviewed, notes of distinct types of interactions were made on Post-its. These were then arranged to form interaction categories and individual interactions (Figure 3).

Figure 3. Interaction categories developed for the search task during open coding

Once an initial set of categories and interactions were developed for each of the four tasks observed, they were set-up as coding schemes in The Observer XT (Noldus, 2016). The coding schemes were further developed during early stages of coding within The Observer XT. This involved the addition of new codes to better explain interactions, and the combining of similar codes to reduce the complexity of the coding scheme. Through this process, six taxonomic groups were developed that were applicable to each of the tasks performed by security officers in the mandatory passenger screening process (Table 2).

Airport passenger screening task composition

Results presented in this section analyse the composition of interactions in each task, and the direct relationships that occur between interactions in different tasks within the overall passenger screening process. Total time durations of the interactions performed by each participating security screener were computed using the Observer XT. Mean percentages for interactions were then computed for each individual participant, and then averaged over all participants.

Load

The Load task is primarily comprised of Bag/item Interactions (56%) and Passenger Interactions (28%). Periods of Off-task (11%) and Staff Interactions (5%) were performed to lesser extent (Figure 4).

![Figure 4. Interaction categories and interactions performed during the load task](image)

The focus of security officers’ Bag/item Interactions performed during the Load task was to ensure that passengers’ carry-on luggage was inserted into the x-ray machine at appropriately spaced intervals (Spacing Bags 39%). This was followed by separating restricted items (e.g., liquids, aerosols and gels (LAGs); umbrellas; and, laptops) from a bag and placing them on a tray (Separating Items onto a Tray, 9%). Repositioning Bag/items (6%) was performed to reduce any clutter in trays and to ensure that the bag was in the optimal position to be screened by the x-ray. Removing Trays (2%) from the belt was performed to reduce clutter caused by unnecessary trays throughout the screening process.
Passenger Interaction types were performed to encourage passengers to divest prohibited items or items such as liquids that are required to be presented on trays for x-ray screening (Asking Questions About Items, 18%). Other types of Passenger Interactions involved Giving Instructions (7%) such as asking passengers to move their belongings down, and Returning Items (3%) that were not required to be screened, such as passports and boarding passes.

Staff Interactions occurred when Receiving Re-runs (5%) from other tasks in the screening process. For example, after a prohibited object had been removed during the Search task, the bag is required to be re-run through the x-ray to ensure the threat is cleared.

**Metal detector**

The Metal Detector task had the least diversity of interactions of the four tasks observed (Figure 5). Visual Interface Interactions (86%) with the metal detector unit were the prevailing interaction. Passenger Interactions (13%) were performed occasionally, while Staff Interactions (1%) were rarely performed.

![Figure 5. Interaction categories and interactions performed during the metal detector task](image)

Visual Interface Interactions performed during the Metal Detector task involved Watching for Alarms (86%) as passengers walk through the metal detector.

Passenger Interactions performed during the Metal Detector task comprised of Giving Instructions (10%) to passengers, such as when it was clear to proceed, when to wait, and when to stop and go back. Less frequently, security officers were required to explain the explosives trace detection randomiser (Explaining ETD Randomiser, 2%), a visual cue that is
present on the metal detector when a passenger is randomly selected for ETD screening. Security officers were also required to explain to passengers when they had triggered an alarm due to metallic items on their person (Informing of Result, 1%).

Staff Interactions were infrequently performed during the Metal Detector task. They were used to request that another officer check the passenger for metallic items on the body using a hand wand (Requesting Wand, 1%).

**X-ray**

The X-ray task had the greatest diversity of interactions of the four tasks observed (Figure 6). Visual Interface Interactions (60%) comprised most of the task, followed by Off-task (22%). Bag/item Interactions (7%) and Staff Interactions (7%) each comprised small percentages of interactions. The percentage of Passenger Interactions (2%), and Physical Interface Interactions (1%) performed during the X-ray task were low.

![Interaction categories and interactions performed during the x-ray task](image)

Visual Interface Interactions performed during the X-ray task focused on Searching Images (33%) for prohibited items or items of interest, and Examination of Items (27%) for the purposes of identification and evaluation.

Bag/item Interactions were performed during the X-ray task when a prohibited item or item of interest was identified and further action was required. Performing Manual Search (2%) of a bag was required for the removal of a threat or restricted item, and to investigate items that could not be identified through Visual Interface Interactions. Performing Re-runs (2%) was required when a bag/item had to be scanned through the x-ray a second time. This involved
transporting a bag/item to the officer at the Load position. Visual Inspection of a bag/item (1%) involved short visual check of the bag while it was on the conveyor belt, normally to check a feature on a bag or confirm the identity of an object in a tray. Intercepting Bag/item (1%) occurred prior to Staff Interactions, and involved removing a bag/item from the conveyor belt.

Staff interactions were performed with the security officer in the Search position when a prohibited item or item of interest was identified and further action was required. Requesting Manual Search (5%) was performed when a restricted item or item of interest was required to be removed or evaluated. Requesting Re-run (1%) occurred when the x-ray screener required the bag to be rescreened, for example, to look at the bag from a different angle. A Discussion (1%) between security officers was performed to evaluate and decide on an item of interest shown on the visual display, without requiring further action such as a re-run or manual search.

Passenger Interactions were performed to support Bag/item Interactions, and involved Asking Questions (2%) about a bag/item prior to, and during, a manual search or re-run.

Physical Interface Interactions were performed to support Visual Interface Interactions. Image enhancement functions (Applying IEFs, 1%) were used to alter the appearance of the image on screen to assist identification of an item of interest or to overcome difficult image conditions, such as clutter.

**Search**

The Search task comprised of a combination of interactions with staff, passengers, and passengers’ belongings (Figure 7). Bag/item Interactions were most prominent (30%), followed by Staff Interactions (23%) and then Passenger Interactions (12%). Off-task periods were frequent (35%) in the Search task, as the performance of activity was dependent on search requests from the X-ray task.
Clearing Trays (18%) left behind after passengers had collected their belongings comprised most Bag/item Interactions. The remaining interactions with bags/items were concerned with search actions; Searching Bag (10%) and Separating Items onto a Tray (2%).

Interactions with staff occurred with two positions; Load and X-ray. Delivering bags/items to the load position to be re-run through the x-ray (Delivering Re-run, 20%) accounted for most of these interactions. This action occurred when the security officer in the X-ray position wanted another look at the bag, or following the search of a bag. Receiving Search Instructions (3%) from the security officer in the X-ray position occurred prior performing Bag/item Interactions.

Passenger Interactions were performed to assist search activity. This involved Explaining Process (7%) to passengers, Assisting Gather and Repack (3%) of bag after they had been searched, and Asking Questions (2%) to gain information of an items and its location within the bag.

Relationships between interactions in the overall passenger screening process

The tasks discussed in the previous sub-sections are performed by a single security officer and each serve a specific purpose in the overall passenger screening process. At various points during these tasks, however, interactions performed by security officers share direct relationships with other tasks in the process. They therefore can influence the overall functioning of the passenger screening process. Figure 8 highlights the direct relationships
that occur between interactions within different tasks throughout the passenger screening process.
Figure 8. Direct relationships between interactions in the overall passenger screening process
Direct relationships between tasks are initiated by the security officer in the X-ray position when an item is encountered that cannot be resolved by examination or by using physical interactions with the interface. This event is represented by the $\otimes$ in Figure 8.

To resolve the issue, the security officer performing the X-ray task must first intercept the item (Intercepting Bag/item 1%). There are two types of interaction sequences that follow this: (i) performing a Staff Interaction with the security officer in the Search task; or (ii) performing a Bag/item Interaction themselves.

(i) In the case of a staff interaction between security officers in the X-ray and Search tasks, the officer in the X-ray task will choose one of three options. If the problem can be resolved easily, a Discussion (1%) will take place. If further action is required, then the officer in the X-ray task will Request Re-run (2%) or Request Manual Search (2%) depending on the type of item. For example, a laptop left in a bag may only require a re-run to make the image clearer, while oversized liquids or sharps must be removed. In either case, the security officer in the Search position will receive Search Instructions (3%) from the officer in the X-ray position. They will then engage the passenger to explain the reason for the search (Explaining Process 7%) and gain information about the item in question (Asking Questions About Items 2%). Alongside these interactions with the passenger, the security officer must search and locate the item (Searching Bag 10%) and prepare the items for a re-run (Separating items onto a tray 2%), before Delivering Re-run (20%) to the officer in the Load position.

(ii) If the officer in the Search position is not available, then the officer in the X-ray position will perform a Bag/item Interaction themselves. This includes Asking Questions About Items (2%), and then interacting with the bag/item to Perform Manual Search (2%) or Perform Re-run (2%).

In either of these scenarios, the security officer in the X-ray position is required to shift their attention away from the visual interface. Consequently, passengers and their belongings are not being processed for up to 13% of the x-ray task while the officer in this position is interacting with staff, passengers, and bags/items. Subsequently, this has a flow-on effect, accounting for up to 42% of the interactions performed during the Search task, and 5% of the Load task.

**Discussion and implications for design**

Each of the four tasks in the mandatory passenger screening processes are defined by the interactions that they are comprised of. In this paper, six taxonomic groups were developed to quantify these interactions: (i) Visual Interface Interactions, (ii) Physical Interface Interactions, (iii) Bag/item Interactions, (iv) Passenger Interactions, (v) Staff Interactions, and (vi) Off-task. These groups and the interactions comprising them can be used as a framework with which to inform the design of current and future passenger screening processes. Based on the composition of interactions, the passenger screening process can be divided into two main interaction focuses: (i) Interactions with passengers and their belongings; and, (ii) Interactions with interfaces and technology (Figure 9).

(i) Interactions with passengers and their belongings

Interactions with passengers and their belongings featured most prominently within in the Load and Search tasks, occurring at the beginning and end of the mandatory screening process. In an environment known for complex and sophisticated technology (Graves, et al.,
2011), the prominence of interactions with passengers and their belongings emphasises the importance of designing for effective passenger engagement. Interactions with passengers at the beginning of the screening process are particularly important for passengers who are uninformed about the process and its requirements. If a passenger is uninformed, it is likely that they will not be prepared properly and thus be subject to further checks and delay. If a prohibited item is left in a passenger’s bag, for example, a security officer is required to have the item removed from the bag and then scanned again. This type of delay is inconvenient and frustrating for a passenger, particularly if they do not understand why it happened in the first place (Kirschenbaum, 2013). This can lead to dissatisfaction with the screening process, which has been linked to passengers’ lower perception of screening safety. Although airports are likely more interested in actual security efficacy, a passengers perceived safety is also important as it “determines travellers’ willingness to take airplanes and pay for the cost of the screening process” (Sakano, Obeng, & Fuller, 2016, p. 129).

Figure 9. Framework highlighting interactions to be prioritised in the passenger screening process

The effect of delays caused by items and bags that need to be re-run through the x-ray are felt beyond passenger experience, and influence when and how a range of interactions are performed throughout the screening process. Results presented in this paper (see Figure 8) have demonstrated the considerable time and resources required to have bags searched and re-run. Whether security officers request these actions or perform them themselves, it equates to time when they are not processing images of passengers’ bags. In effect, this renders the
entire process stationary, and thus decreases total passenger throughput and economic efficiency.

According to Kirschenbaum (2013), a large percentage of the delays that occur due to bag searches and re-runs can be accounted for by uninformed passengers. Kirschenbaum reported that between 85% and 90% of prohibited items that delayed passengers from continuing through the checkpoint were liquids that were either left in bags or that exceeded 100ml. Given this, it stands to reason that a substantial percentage of these delays can be addressed by better designing for passenger preparation and item divestiture. Kirk, Popovic, Kraal, and Livingstone (2012) provide strong support for this, suggesting that passengers’ preparation is a critical requirement for airport efficiency as it encourages passengers to proceed through the airport more quickly. Based on their research, it was recommended to their partner international airport that they provide additional preparation space and staff to assist passengers’ preparation well before they get to the main queue of the security checkpoint. This resulted in “a reduction in average waiting times from 20 minutes to 3.9 minutes, and an increase from 260 passengers per hour to 340 per hour being processed through security” (Kirk, et al., 2012, p. 10).

As long as passengers are subject to restrictions on common items (e.g. LAGs), and special preparation of others (e.g. laptops) is required, achieving efficient passenger processing is likely to be a challenge for the design of passenger screening processes. Using our taxonomic groups, it is proposed that interactions with passengers and their belongings are prioritised in the first and last stages of the passenger screening process. A first step for this is to implement changes to reduce or eliminate non-passenger focused and repetitive interactions such as spacing bags. While this is an important interaction that reduces visual clutter for the officer performing the X-ray task, it also requires constant attention from the security officer in the Load position. Our results show it comprises 39% of the Load task. This time could be easily freed up by implementing currently available systems that incorporate automatic bag spacing (e.g. Herbert Systems). Removing the need for security officers to perform this task would provide substantial additional time to focus on interaction with passengers and their belongings to encourage divestiture.

Systems that automatically space bags often also feature automatic tray return. Incorporating this technology would remove the need for security officers in the search position to clear trays, which comprised a substantial percentage (18%) of the Search task. Freeing up staff in the Search task means that they are more likely to be available when a search or re-run is required. This means that the officer in the X-ray position would not be required to search or re-run bags themselves, and can focus entirely on processing images of passengers’ bags.

In addition to improving interactions during search and load tasks, supporting literature (Kirk, et al., 2012; Kirschenbaum, 2013) highlights the need to ensure that passenger utilised facilities prior to entering the security checkpoint be designed to encourage effective preparation. The current strategy to do this is properly placed signage and the provision of divestiture spaces to encourage preparation (Dallas/Fort Worth International Airport, 2005; Kirk, et al., 2012; Passenger Screening Task Force Architecture and Technology Workgroup, 2006). Despite persistent recommendations, however, the problem of item divestiture remains. Perhaps simply providing divestiture space and instructive signage is insufficient, and greater attention needs to be placed on the contextual design of preparation locations and spaces. There is strong evidence to show that people use contextual features to help them understand what to do and where to go in environments. Carpman, Grant, and Simmons (1984) found that environmental cues, rather than signage, were most important for people
when entering a hospital. Similarly, Cave (2016) has shown that airport passengers often use environmental features to inform them on what to do and where to go.

To enhance the contextual cues available to passengers, persuasive design methods (Lockton, Harrison, & Stanton, 2010a; Torning, 2013) can be employed. In particular, design patterns from visual and cognitive design lenses, which draw ideas from semiotics, product semantics and gestalt principles, are applicable. For example, grouping security preparation activities with similar preparation activities, such as filling out outbound passenger cards, might encourage passengers to perform these activities in a single step before entering security. With passengers likely to spend longer to achieve multiple grouped tasks, there is an additional opportunity to capture their attention with information sources, such as signage. The design of such spaces should also promote visibility between passengers to encourage opportunities for discrete user feedback. Providing discrete opportunities for feedback from people with equal status in the system can provide useful cues for how to behave (Lockton, Harrison, & Stanton, 2010b). This affordance is particularly valuable for uninformed passengers as it allows them to follow cues from others who are familiar with the process.

(ii) Interactions with interfaces and technology

Interactions of greatest priority during the X-ray and Metal Detector tasks are the visual interactions with interfaces to detect prohibited objects and alarms. Eliminating peripheral interactions with passengers, their belongings and staff during these tasks will allow greater focus to be placed on processing images, thus facilitating passenger throughput. Improving passenger preparation and the divestiture of prohibited items will contribute to this. However, security officers must also negotiate a range of image based factors, such as clutter and opaque objects, that can result in error and delay (Schwaninger et al., 2008). Advanced screening technologies will have a significant impact on this, and will facilitate greater focus on visual interactions with interfaces to improve processing capabilities. CT luggage screening systems, for instance, enable the rotation of x-ray images of passengers’ bags, leading to better object visibility (Wetter, 2013). Although cost prohibitive at this point, deployment of CT technology will contribute to reducing instances of bag re-runs and manual searches of bags, if not eliminating them all together. Additionally, this technology will be a critical factor in realising remote screening, a key element of ‘Smart Security’ (2016). The recapture of space previously occupied by screening technology offers enormous potential for overhauling the design of the security checkpoint to maximise security officers’ engagement with passengers and to enhance passenger experience.

Conclusion

This paper has identified six taxonomic groups to describe the different types of interactions performed during the mandatory passenger screening process at an Australian international airport. Quantification of the interactions within these groups, and analysis of the relationships that occur between interactions in different tasks, have shown the effect that interactions have throughout the passenger screening process. Staff Interactions and Bag/item Interactions performed during the X-ray task are shown to be of particular interest. Not only do these interactions cause delay to the X-ray task but they are directly related to the functioning of the Search and Load tasks. These interactions are also responsible for passenger delay and decreased throughput. The cause of these delays, however, is directly related to passenger preparation and divestiture of prohibited items. While technology is often positioned front and centre in this process, these findings suggest that emphasis also be placed on improving interactions between security officers and passengers.
From our findings, we have proposed a preliminary framework outlining the interactions types to prioritise in different stages of the passenger screening process. The framework emphasises interactions with passengers and bags during the first and last stage of the security process, and visual interactions with interfaces during the middle stage. Emphasis of these interactions can be facilitated by assistive technology that automatically spaces trays in the Load task and returns trays in the Search task. Additionally, advanced screening technologies such as CT systems will assist security officers’ visual interactions, thus reducing requirements for bag re-runs and manual searches. It is imperative that the design of passenger screening processes focus on enhancing both technology and human interactions. The significance of this research lays in its potential effect on the three functions of the security screening process: passenger experience; throughput and security. As this research progresses, we expect to further address these functions by extending the taxonomy of interactions to include non-mandatory screening processes.

Abstract

The ethical dimensions of basing a typeface on existing faces are unclear. Commentary about “clones” from critics and type designers alike are confused and contradictory. Few writers consider the issues systematically. Misunderstanding of copyright law and unreflective versions of moral rights claims dominate discussion. Open discussion of the models for a type design avoid claims of plagiarism and also affect the reception of the new typeface.

Keywords: ethics, copying, plagiarism, type design, typography

What the Font

Simon Garfield’s Just My Type—a book about type aimed at the general public— was released to warm reviews by USA Today, National Public Radio, the Guardian, the Washington Post and many others. [Wilson 2011, McAlpin 2011, Hollland 2011, Drabelle 2011.] I wasn’t happy with the book, however. I’m somewhat type obsessed and, as The New York Times said in its (quite favorable) review of the book, “font wonks fight.” [Maslin 2011.] To paraphrase an old joke, get four typographers together and you’ll hear five different opinions. This isn’t the forum for most of my objections to the book but the “Pirates and Clones” chapter offers an interesting discussion of the ethics (and legalities) of copying.

Garfield begins that chapter with Helvetica and Max Meidinger. The man who drew what may be the world’s best-known typeface received no royalties and died “virtually penniless.” [Garfield 2011 p 221] Garfield postulates that Stempel (Helvetica’s foundry) and Linotype (Stemple’s parent company) haven’t made as much money as Microsoft “for the simple reason that if your font is any good, it gets copied.” Apparently, Garfield thinks that Microsoft software doesn’t get copied.

If Garfield’s economic analysis is flawed, his formal and ethical thinking is worse, as illustrated in his discussion about the problem of Helvetica “clones.” “Clone” is an early 20th century coinage from botany. It comes from the Greek “klon”—a twig—and it means that two or more organisms have identical genetic material. By extension, the word is used to mean anything that replicates or, by a weaker analogy, approximates or resembles something else. Garfield’s description of Helvetica “clones” as “often with tiny modifications” makes some sense. The charge of cloning clearly implies close copying. Just My Type tells us that “[f]onts such as Akzidenz Grotesk Book and Nimbus Sans Bold display similar attributes to Helvetica; one clone even calls itself Swiss. But the biggest transgressor, in terms of global impact, is Arial.” We get no clue how Garfield thinks his use of the “clone” designation is affected by the fact that Helvetica was largely an update of the much older Akzidenz Grotesk (thus as much a “clone” as some of the faces he derides with the term) or that Nimbus Sans was designed by Helvetica’s designer, Max Meidinger, and that some parts of the Nimbus family predate Helvetica (putting clones and time machines into the same
Most of Garfield’s dismissal of the clones is directed at Arial—“the Helvetica lookalike favoured by—you can probably guess this—Microsoft.” (I should probably disclose that I have a sometimes-irrational antipathy for all things emanating from Redmond so I resent being put in the position of having to defend Microsoft about anything.)

The cloning story goes on to tell us that “[m]any people will prefer [Arial] to Helvetica, for it has a slightly softer and more rounded tone. . . . Arial has always sold itself on these attributes, drawing attention to its fuller curves and angled terminals, claiming it is less mechanical and industrial than other sans serifs. These ‘humanist’ characteristics ensured it was ‘more in tune with the mood of the last decades of the twentieth century’.”

“A remarkable thing about Arial,” we learn from Garfield, “is that it has many deliberate differences that—when you get used to them—are as different from Helvetica as pineapple is from mango. . . .” He cites specific differences and he is right about those.

So why is Arial “still regarded—and rightly so—as a cheat”? “[I]t was the fact that its width and other key elements fitted exactly the same grids that Helvetica occupied, thus making it interchangeable in documents and printing or display software,” and “Arial was cheaper than Helvetica, and [Microsoft] wanted to save money on the license fee. A sound business decision, unless one objected to the principle of capitalizing on another’s artistry. Monotype [the company that produced Arial] was not acting illegally, and in any case maintained—with some justice—that Arial was an updated version of their own Grotesque series from more than a century earlier.”

So Arial replicates/approximates/resembles Helvetica—just like pineapple replicates/approximates/resembles mango—and this despite being patterned after something that existed long before the “original” did. The worst problem, as Garfield would have us believe, is that it capitalizes on the proprietary artistry of character widths.

Mocking the incoherence of Just My Type is easy but Garfield isn’t the only one confused about the ethics of typeface copying. The argument that Arial and Helvetica are too much alike while not being enough alike seems to be a common and perhaps even the prevailing attitude among those who care about type design—including those who know a lot more than Garfield apparently does. Type designer Mark Simonson writes under the melodramatic heading “The Scourge of Arial” that “Monotype was a respected type foundry with a glorious past and perhaps the idea of being associated with these ‘pirates’ was unacceptable. So, instead, they found a loophole and devised an ‘original’ design that just happens to share exactly the same proportions and weight as another typeface. . . . This, to [Simonson’s] mind, is almost worse than an outright copy. A copy, it could be said, pays homage (if not license fees) to the original by its very existence. Arial, on the other hand, pretends to be different. It says, in effect, ‘I’m not Helvetica. I don’t even look like Helvetica!’, but gladly steps into the same shoes. In fact, it has no other role.” [Simonson 2001]

If Arial is so reviled, why is it so broadly used? Although some people make claims the about bad taste of the masses, choices often have little to do with taste. Arial comes with Microsoft software so these days, it’s users of Helvetica who are more likely to take advantage of the
spacing match with the nearly-ubiquitous Arial. If Arial and Helvetica are fungible in the most mechanical sense, the exchange is likely Helvetica being used as a replacement for Arial. It’s the “network effect.” People are on Facebook (or Twitter or Tumblr or whatever) rather than MySpace not because of more powerful software or better interface or more acceptable policies about privacy and advertising. Just as Dolores Hart, Yvette Mimieux, and their friends went to Fort Lauderdale for spring break in 1960 because it was “where the boys are,” people use a social network where there’s the opportunity to be social. People use Microsoft Word because they have to share work with people who use Microsoft Word.

People use Arial because they assume they can share a document with anyone and that person will have the font installed. Being able to print pages that come out the same length as they were when they were created in Helvetica may have been a feature at one time. Now it’s more likely that Helvetica pages will fit the same space as ones originally in Arial.

**Legal protection for type design**

The ethics of copying and influence in type design are complex and unclear. The legalities under US law are slightly simpler but still somewhat cloudy. Although they get lumped together in discussions of “intellectual property,” copyright and patent are separate and have quite different rules. Copyright covers work that might be called creative, literary, or artistic. It does not affect practical inventions. Patents cover inventions. From the perspective of US copyright law, an alphabet is a functional thing, more akin to pencil than to a poem, so a typeface isn’t eligible for copyright protection. [4th Circuit 1978] Letters are, by Copyright Office standard, long established so any new typeface is just a variant of something firmly in the public domain. (If a typeface were highly decorative, the portions separable from the letters themselves might be protectable under copyright.) The Patent and Trademark Office sees no new invention in a typeface. From the standpoint of reading, pretty much any typeface works like any other typeface so is, from a patents and inventions perspective, type is clearly in the public domain. That doesn’t leave typeface designers much legal shelter. (Copyright laws, although affected by international agreements, are not universal. While US copyright does not cover typeface design, German law covers typefaces as original works since 1981, as does English law since 1989.)

Copyright has been used to protect fonts as opposed to protecting typeface design. Let me try to translate that into English:

In the days of lead type for letterpress printing, “font” meant what comes in a single type case—a particular instance of a typeface. Helvetica Medium was a typeface. The various weights and styles of Helvetica were a type family. Helvetica Medium in ten-point size (i.e., the stuff that goes in one type case) was a font. Helvetica Medium in twelve-point size was another font. Helvetica Medium Oblique, Helvetica Bold, Helvetica Medium Condensed—all in ten point size—were each a different font and the same typefaces in twelve point size would be yet other fonts. That distinction makes little sense in an era where most type is in the form of electronically encoded outlines that can be scaled to any size. Even though most people (including a few experts on type and type design) tend to use “font” as synonymous with “typeface,” pedantic twits like me make the distinction between a traditional definition of typeface (the
design of an alphabet) and the meaning of font as the physical instance of a face. In current use, the physical instance is a computer program. (You may think that you are typing something in Microsoft Word and in Word alone but a separate set of code describes each typeface that appears.) So one font isn’t distinguished from others by occupying a different case; it’s a separate computer program that defines the distinction. Even though the printed result might be indistinguishable, Helvetica Postscript format for the Macintosh, Helvetica TrueType format for the Mac, Helvetica TrueType format for Windows... is each a different font.

Why does this distinction matter? Copyright does not apply to typeface design in the US but computer programming is, for copyright purposes, seen as akin to literary expression. The designing of a typeface cannot result in a work protected by copyright but programming a font can. Type designers are not computer programmers but at least one court has accepted the claim that the choice of placement of points in a drawing program is a creative act even though the choice of the shape of the resultant curve is not. [7th Circuit 1996] US copyrights on fonts are still few and far between and their ultimate legal status is still not clear. The irony is that copyright is meant to protect expressions and most people (including most type designers) would consider the shapes of the letters themselves—not the computer code that records them—to be the expressive stuff.

As much as I’d like to see type designers protected from predatory practices and able to make a living, the legal status of typefaces in the US makes some sense. Copyright cases tend to center on similarity as determined by a jury. I would hate to be in the position of trying to explain to twelve randomly selected people why Helvetica doesn’t infringe on Adrian Frutiger’s Univers, an earlier type family with some similar characteristics, especially when so many “experts” refer to even less similar typefaces as “clones.”

Of course, the law isn’t the only restraining force on our actions. Even when the US Supreme Court affirmed that making movies of crushing small animals is legal, [Supreme Court 2010] most of us didn’t merely choose to do something else with our free time; we thought the practice repugnant and would not have considered making such films (or crushing such animals) even if we had somehow thought of it. By the same token, typeface designers often have ethical qualms about copying typeface designs that go well beyond the letter (pardon the expression) of the law. Unlike more organized and more heavily scrutinized activities, there isn’t a clear or consistent ethical code for type designers. The logic of beliefs about type designs as “proprietary” is often cloudy. Yet the subject of copying typefaces tends to produce more outrage among type designers than, say, crush movies do for the population at large.
A brief history of typeface cloning

Until the middle of the twentieth century, most printing was done using a process called letterpress. Just as with a rubber stamp, a raised surface was inked and paper was pushed against the raised surface. Type was formed as blocks of lead, thus type was a real physical object. The cloning of typefaces—in the sense of making more- or-less exact copies—has a long history but until recently it was the domain of type foundries. In the late 18th century, when Fry advertised copies of Caslon’s faces, [Updike 1922] it took many months of skilled punch cutting to make (quite inexact) copies. Typefaces were created by first carving each letter by hand in a piece of steel (a “punch”) that was used to indent the letter in the brass matrix that forms the bottom of the mold for making lead type.

By the mid 19th century, the copying technique was to buy another foundry’s type and duplicate it by electrotyping matrices. [Lawson 1990 pp 57, 350] Essentially, the lead type was plated then removed from the thin metal of the plating. The plating was reinforced and the resultant cast from the original type was used to make a mold to create more type that matched.

By the end of the 19th century, punch cutting had been replaced by the pantograph, a machine that cut matrices by tracing large renditions of characters, reducing them to the desired size. This made copying easier, requiring less in the way of effort and professional skill. It was still a significant undertaking, however. [Lawson 1990 pp 390–391]

By the 20th century, the real money was in typesetting equipment and manufacturers such as Linotype and Monotype largely treated typefaces as accessories to their expensive machinery. (Linotype, as the name implies, made equipment that dropped the matrices—the indented brass that forms the shape of the letter—into a mold and cast complete lines of type. Monotype’s equipment cast letters as individual pieces of lead but, like Linotype, arranged type using keyboard commands rather than requiring a compositor to pick individual letters from a type case and arrange them in a form, carefully adjusting spacing by hand.) Having a “version” of any popular typeface was an important sales point for typesetting equipment; typeface design “piracy” was, for most of history, the domain of the large type companies.

Letterpress printing gave way to offset lithography (where photographic printing plates are a flat surface and ink distribution is controlled by water on the plate) as the dominant form of commercial printing in the second half of the 20th century. This allowed the rise of photo type, where type is set using photographic negatives exposing light sensitive paper. A character could be drawn in ink and placed under a camera with relatively little labor so more typefaces were produced. Copying the characters of an existing typeface was equally simple so the practice of reproducing faces otherwise available only on competitors’ systems became even more widespread.

When I started as a graphic designer, nearly all designers specified Helvetica at some time so, to be commercially viable, every typesetting equipment company had to have a version. Several of the typesetters I used had the low-end Compugraphic systems; the version they had was called Helios. Helios was clearly a Helvetica clone. I couldn’t tell the difference then and I
assume I could not tell

Helios from Helvetica now (had Compugraphic not been absorbed by Agfa in 1989 and Helios not disappeared down the rabbit hole of technological history.)

There were urban legends that Compugraphic made the hyphen shorter and that if you just changed one thing on a typeface, copying was okay. The fact was, the letter shapes were not (and are not) legally protectable under US law. The name, however, was a trademark, so the clones couldn’t be called Helvetica. When I spec’ed Helvetica, my typesetter delivered Helios without apology (unlike the waiter who is likely to ask “Is Pepsi okay?” when you order a Coke.)

There were some attempts to reign in the copying of typefaces by the major foundries or at least get compensation for the designers; legendary type designer Hermann Zapf mounted a campaign and finally resigned in 1993 from Association Typographique Internationale (ATypeI) in protest over copying typified by Monotype’s Book Antiqua, a typeface modeled closely on Zapf’s Palatino.

Three type designers started International Typeface Corporation in 1970. Unlike earlier type companies, ITC did not make metal type and did not sell typesetting equipment. They licensed their designs for a variety of phototype and digital systems and other uses such as Letraset rub-on letters.

Although ITC moved the type design world away from being an appendage to heavy equipment manufacturing, the advent in the late 1980s of small general-use computers as the primary means of typesetting changed both type design and the type industry. As use of the Macintosh computer proliferated, so did the market for typefaces. Programs like Fontographer made the production of working typefaces easier. Producing a working typeface was within the reach of any designer. The nature of fonts for small computers made copying typefaces trivial. Even as the market for type boomed, the problem of “piracy” exploded, presaging the recording industry’s experience of a decade later. Suddenly the major typeface companies (until recently the big typeface “pirates”) became the voice of the ethical protection of the rights of type creators.

Much as the computer revolution has made copyright issues—previously only important to professional writers and creators—relevant to a broad range of the public. The relative ease of creating a working typeface expanded the ranks of professional type design and, in turn, the range of people who have ethical concerns about type copying. An esoteric issue became mainstream. “Not only does the Macintosh enable anyone willing to invest the time to design and manufacture typefaces, it has also turned every computer user into a potential purchaser of fonts, making typefaces a rather valuable economic commodity” writes Emigre magazine editor/publisher Rudy VanderLans. (Emigre was an important graphic design magazine for over twenty years.) “Since type design has been a very exclusive field until recently,” writes type designer Zuzana Licko, “there is little information available as compared to other design disciplines. Often, people tend to forget that typefaces are in fact designed, and not merely static forms handed down from generation to generation.” (Licko and her company, Emigre
Type, were among the most important forces in the changes in type design that started in the late 1980s; she is VanderLans’ wife and business partner.) [Licko 2000]

In an era where fonts were no longer tied to proprietary typesetting equipment, the licensing restrictions that gave rise to Helios and its ilk became unlikely to be a reasonable excuse for the direct copying or mere software format conversion of typeface software. If they are at all thoughtful about it, even the most rabid copyright opponents tend to look down on doing nothing but gathering the work of others, copying, and reselling it (with or without a name change.) Even if one believes that we would be better off with no copyright law, it is hard to applaud commercial activity on that level. The tricky questions of typeface design ethics emerge when we look beyond direct reproduction and cloning.

**Classifying copies**

Although most type designers would characterize their work as creative, original, and unique, designing a useful and readable typeface requires working under great restraints.

Inventing truly unique forms would render the alphabet unreadable. In the design of type meant for continuous reading—as opposed to “experimental” or “novelty” typefaces—too much originality destroys the value of a typeface.

Important differences between typefaces are invisible to most people, making standards of originality less clear.

Even if we agree that all of culture is based on previous culture, the principal is even more obvious in type design. All useful letters are necessarily based on previous letters. How, then, do we determine the difference between preservation, progress, and plagiarism?

Plagiarism is not copying. It is lying about copying. This means that honesty with oneself and with others is a good first step. As type designer John Downer notes regarding revivals (new typefaces based closely on earlier typefaces), “The integrity of a typeface revival depends not solely on what the designer does to create a workable version of an old idea; it also depends on what the designer, or the designer's copywriter or publicist, has to say about the genesis of the design.” Downer points out that inaccurate or misleading discussions about a typeface can lead to disputes. On the other hand, “if the story behind the designer's effort stands up to the scrutiny of type historians and scholars, a revival has a far better chance of being considered a welcome addition to the world of revivals—not so much for being a ‘servant’ to a given typographic model as for bearing a relationship to its history.” [Downer 2003]

Downer suggests a range of categories from revivals to knockoffs. He says that knockoffs “don’t rate as revivals because they don’t revive.” He also characterizes encores and extensions as “milking the Cash Cow one more time.” His disapproval is pretty clear for most typefaces that would fit those descriptions.

Downer’s claim about people’s “milking the cash cow” assumes to understand the motivation
of copyists and to know that financial gain is at the heart of the replication. That’s not clear to me. Some typeface releases seem to be akin to fan fiction where the author of the project wants to be immersed in an admired creation. Some seem to be exercises in understanding an admired typeface. Someone who painstakingly rebuilds letterforms or makes significant changes to the computer file may have raw financial gain in mind but making a blanket statement about motivation is difficult. Even though I generally agree with Downer’s assessment of the ethics, I can’t assume to know the mind of the copyist.

Rudy VanderLans suggests that “Ethics, the rules or standards of conduct governing the members of a profession, is all we have to guide us. Milton Glaser, appropriator extraordinaire, and probably one of the most ripped off designers alive today, once said something to the effect that he wouldn’t copy anybody’s work unless the originator was dead. In case of doubt, that’s not bad advice.” Clearly VanderLans sees copying in terms of injury—financial and possibly personal—to the creator of the original typeface. Another argument for his and Glaser’s rule of thumb connects with Downer’s call for sensitivity and a real appreciation for history before copying. Responding to a typeface that is new and popular might not result in as thoughtful a project as one whose place in history is more secure.

But waiting for people to die has, in addition to ghoulisf possibilities, some dissatisfactions. One is that it apparently assumes a version of moral rights albeit (unlike many moral rights claims) an un-inheritable one.

One mode of copying that doesn’t fit neatly into any of Downer’s categories is sampling. “A sampled font . . . is a hybrid made up of distinctive parts copied directly from existing digital fonts” VanderLans writes. [VanderLans 1996] VanderLans and many designers object to copying from computer files. Claims that such acts are too easy have a similar tone to objections to photography or music sampling. Objections to using someone’s work based on the amount of labor they put in seems to value labor over the creative vision we supposedly revere.

My typeface Rosemary, designed for production as wood type for letterpress printing, might be described as a sampled typeface or, more accurately, a mashup. (Craig Malmrose of Trade Union Press in Ayden, North Carolina, made the Rosemary typeface in wood.) It has the even stroke weight usually associated with san serif type and short slab serifs with heavy bracketing usually associated with faces that display much more thick and thin. On the poster announcing the typeface, I described it as “the love child of Trade Gothic and Clarendon.” Is it a problem that Rosemary’s O is pretty much indistinguishable from Trade Gothic’s? When typeface designers rhapsodize about their creative freedom in creating a capitol Q or an ampersand, the O isn’t usually mentioned, especially in a typeface with very even weight. John Downer’s honest commentary test gets me past any real plagiarism claim but it’s clear to me that universal approval of almost anything in the typeface design world is highly unlikely.

Restricting copying

Different typeface designers have different “rules” of proper type design procedures. Ethical objections to using the font files of other typefaces (AKA “point theft”—the software that used
to draw most typefaces relies on points on outlines of letters to establish their shapes) are common as are objections to auto tracing other alphabets. The usual rationale is that these are shortcuts; real type design is a lot of work and point rustling and auto tracing avoid the labor and appropriate the efforts of others.

If our goals are to encourage creation and to protect or honor originality, “sweat of the brow” arguments are problematic as ethical constraints. It is a lot of work to design a typeface, but nobody would ever choose one face over another based on how long it took to create. The work involved is not the part we value; demanding that creative activity be slow, laborious, or inefficient runs counter to the goal of encouraging creativity. There’s room for debate about what originality means. It’s clear that he answer won’t be found on a card beside a time clock, however.

Type designers’ assumptions about their rights are often expansive, despite the limits of their actual legal protections. For examples, read type design blogs and the EULA (End User Licensing Agreement) of fonts. One example is James Montalbano’s Terminal Design EULA which proclaims a list of prohibited uses including religious or political campaigns. [Montalbano EULA] A EULA may possibly be an enforceable contract, but Montalbano is certainly wrong when he claims, “I get to control what I create. I own the copyright, therefore I control the right to copy.” [Montalbano 2011] He is wrong under US copyright law. Ethically, trying to restrict others’ freedom of expression and religion raises questions.

Type designers’ tendency to be invested in their work is understandable and even admirable. In a sense, they are like songwriters. They make an aesthetic object that in turn depends on someone else making an aesthetic object using it. Even if a moral rights argument made sense, songs and type are in some respects more like brushes than they are like paintings. It would be hard to imagine a blacksmith getting much traction arguing that, as the author of a hammerhead, he should control what sorts of nails others may pound with his creation or what sort of building can result. That doesn’t imply that painters are more important than blacksmiths. But there are ethical dimensions in depiction and different ethical dimensions in forging a hammerhead. It’s hard to justify the idea that creativity is one thing and all creative activities come with the same limitations, the same responsibilities, and the same control over the ultimate results. (Musical compositions are subject to compulsory licensing in the US; if you let someone record the song you wrote, you have to let anyone record it.)

Type designers’ discussions about originality and their proprietary interests in their design can be both bitter and a bit incoherent. I have high regard for type design and for type designers, but it wouldn’t be surprising to learn that someone more distant from that world paraphrased the cliché about academic politics: “so vicious precisely because the stakes are so small.” [quote investigator] Anglo-American copyright protects creation from copying largely because we want to encourage further creation but I suspect that most people don’t care if typeface design is encouraged. If new models of cars or new styles of clothing ceased to appear on a regular basis, many people would be bothered. If new books and magazines weren’t published regularly, readers would be upset (despite the backlog of reading most of us have.) Even most graphic designers wouldn’t be affected by an embargo on new type. Styles and fads would still happen but they would focus on the rediscovery of extant typefaces.
If nobody really cared about new typefaces, however, nobody would bother copying them. The renowned graphic designer Massimo Vignelli famously claimed that there were only a handful of good typefaces and a designer only needed five of them but it’s clear that others disagree. Some people collect so many fonts they couldn’t possibly ever use them but many designers are prolific users of letterforms. Graphic designer Jeff Keedy claimed that designers should make a new typeface for each job. That’s not practical for a range of reasons but it seems that some designers try to buy a new typeface for each job. The search for a face that perfectly fits the project may be never-ending for some and that may mean that encouragement of new designs is not just worthwhile but vital.

If we do want to encourage creative activity such as typeface design, discouraging rote copying and resale makes sense (at least for a limited time.) Anything that limits truly transformative works serves to discourage the sort of activity we claim we want, however. That distinction requires people recognizing the difference between derivative in copyright lingo—anything based on a previous work—and wholly derivative—work patterned after something that doesn’t really offer a worthwhile new contribution. Unfortunately, the difference in type design requires more knowledge and attention than can be expected of most people and more analysis and detachment than can be expected of most type designers.

**Author Biography**

Gunnar Swanson

Gunnar Swanson is a writer, editor, educator, and graphic designer. His writing has covered topics of design education, design business, graphic design, and ethics and has been published on the internet and in trade publications as well as the academic press. Much of his current work centers on issues of copies, copying, and originality. Swanson has taught at a variety of universities and art schools and lead graphic design and multimedia programs across the United States. He lives in Greenville, North Carolina where he is a professor in the School of Art & Design at East Carolina University.
Preserving Craft Heritage by Forging Rural-Urban Connections

Abstract

This study aims to explore the difficulties of preserving cultural heritage in rural areas and to inform better designs of computer systems to support such preservation. In this case study, we observed and documented craft cultures in three rural villages in China. Our methods include photo-ethnography, interview and observation. From analyzing various types of data, we were able to identify issues of cultural heritage preservation, including cultural identity and values. We propose a conceptual system design for an installation and software connecting rural craftspeople and people who appreciate crafts, as a means of fostering a mutual relationship of support and appreciation. We believe this relationship can help preserve cultural heritage in rural areas. Some of the system installation elements were prototyped in scale models. The paper’s primary contribution is the design field research, analysis of design field research, and conceptualization.

Keywords: Traditional craft, Interaction design, Design research, Cultural heritage, Tangible interaction.

This case study focuses on the preservation of rural culture and heritage, which is an important research topic in Information and Communications Technologies for Development (ICTD). We were interested in what roles technologies play in the life of rural craft people, particularly in building cultural identities and confidence. Our ultimate goal is to explore how we can use technology to foster heritage appreciation and preservation by focusing on craft makers in addition to people who appreciate crafts.

Literature Review

ICTD and Traditional Craft

Research and projects in ICTD are targeted to help developing areas and have achieved stunning influence in many ways (Tongia and Subrahmanian, 2006). Many ICTD projects have focused on issues about economic development, education, and health support (e.g. Ali et al., 2007, Perrier et al., 2015, and Vashistha et al., 2015). In parallel, researchers in Human-computer Interaction (HCI) have also targeted cultural identity issues and value manifest (Irani et al., 2010).

In many countries in Asia and Africa, handcrafting is an important tradition. These handcrafting traditions are important as components of cultural practice and heritage.
However, the survival of these handcraft traditions are sometimes at risk. One of the primary threats is globalization. One of the results of globalization is making everything available everywhere, which sometimes come with the side-effects of diminishing the value of unique, local heritage and practice.

Globalization changes people’s attitudes in villages, especially apropos of local craft heritage values, because people in the village come to want the same things that are available and coveted in urban areas (Lu, 2003). In developing areas, inequalities between city life and village life often lead younger villagers to admire modern urban trends, while overlooking the value of cultural artifacts and practices in their local villages. As a result of these trends, the preservation of cultural heritage has become an important yet challenging issue for these developing countries and areas.

Heritage and Interaction Design

Using ICT to preserve cultural heritage has been an important agenda in the HCI community. Many interactive projects have been done to foster appreciation and understanding of cultural heritage. For instance, Petrelli et al. (2016) designed an interactive multi-sensory soundscape to create novel and provocative experiences of a heritage site. The historical site is the remains of the fortifications built during World War I. The soundscape allows visitors to listen to audio stories at narrative points while trekking at the historical site. The audio stories are composed by historical collections about the War, for example, official document and diaries of soldiers. Audio materials and physical landscape are connected by an interactive belt, using Bluetooth and NFC. The interactive belt was inspired by historical images of soldiers and has been designed to fit into the scene. The multisensory experience offers visitors deep understanding of the heritage and strong connection with the historical event the soundscape presented. Other examples include Ardito et al., (2010), Ciolfi and Petrelli, (2015), Griffin, (2010), Ibrahim, Ali, and Yatim, (2015), and Muntean et al., (2015).

The majority of HCI design studies often approach the issue of cultural heritage from the perspective of people who appreciate heritage. For example, Muntean et al. (2015) designed a tangible interface to explore intangible cultural heritage for museum visitors. Belongings, the interactive tabletop they designed, allow museum visitors to access information about the long history of a traditional activity and related knowledge of the ancient culture in exhibition. The interactive tabletop can detect physical replicas of cultural belongings and then provide additional digital information about the belongings. This technology allows visitors to connect physical cultural object with its intangible heritage value by just placing cultural object on the tabletop.

Only a few researchers have looked at this issue from the perspective of craftspeople. These few exceptions include Jacobs and Zoran’s study (2015). Their study focused on a design collaboration between digital makers and traditional craftspeople to create crafts using digital tools. They organized a design workshop with local people in a community in Namibia. The design workshop came up with hybrid design of the local traditional craft by using CAD (computer-aided design) tools.
We believe digitalizing traditional objects and their intangible meanings is only one way of preserving culture. It could also be very valuable to use technologies to support the original crafting practice and keep craft’s cultural value and quality. By doing this, the heritage can live and coexist with the modern society.

The purpose of this design research project is to better understand and design for cultural life and preservation of culture heritage in rural areas. We seek to make sense of how ICT can be used as a material of design for this context. In this study, we present a case study about a three-week long design research in rural villages in China concerning heritage practices. We developed interaction design concepts and prototypes that include the villagers’ perspective in the design phase. In our work, we consider that understanding the local cultural context is crucial and that understanding the concerns of rural people is critical for ICTD projects to successfully addresses cultural issues.

**Research Methods**

To understand how the villagers conduct craft making activities and craft business, the lead author conducted design research for three weeks in three villages in the Yunnan province of China. All three chosen villages - Guandu (官渡), Sanwa Village (三瓦村), and Tengchong (腾冲) (Figure 1) are well known for their crafting heritage and are places in which craftspeople live, learn, and practice their crafts. During the field research, the lead author interviewed 10 craft makers in total, including 5 men and 5 women, visited 7 workshops or individual studios, and observed the public spaces in the three villages. The interviews were semi-structured. The structured part asked questions about the crafting process, how he/she become a craft maker, their crafting business, their relation with crafts’ recipients, their thoughts on preserving crafting practice as a cultural heritage, as well as their personal feelings towards their business of making traditional crafts.
Besides interviews, the lead author also conducted fly-on-the-wall observations for about 60 hours, in the studios (about 18 hours) and in the public spaces (about 42 hours). The observations are aimed to understand traditions and rituals in the village and how crafting practice is involved, the relation between people’s everyday life and the craft practice, the business ecosystem of crafting, and technologies that used for crafting practice. Observations were recorded photographically without interrupting activities. Some people noticed the researcher taking photographs and some did not. No one objected and move over.

To better understand the life of the craftspeople, we synthesized all materials collected from the field work, including photographs, business flyers, as well as notes of interviews and conversations. We did not only emphasize the technological possibilities in designing for the craftspeople’ life and work. Rather, we intended to present their lives as a whole. We were
interested in how their social life, space, activities, and tools intersect with one another. One reason for doing this is that we found it is impossible to interpret the use of technologies in cultural practices without discussing the other aspects of the craftspeople’s lives. Another reason is that we believe only by viewing the space, practices, and tools as a whole, can we find a way to design technologies feasible for the rural people and their cultural practices.

**Results**

**Public Space as a Social Hub for Exhibiting and Practicing Cultural Activities**

At the community level, villagers seek to preserve craft and regard craft as a representation of cultural meanings. However, the differences in traditional craft practices lead to different living styles in different villages. In addition, how villagers conduct their crafting practice depends on the operation of the villages.

Guandu is a tourist spot. Traditional buildings and habitats are well preserved in this village. Social activities take place in public spaces – a park or a square, which include mainly traditional Chinese activities, such as singing Chinese opera and playing traditional music instruments. At Guandu, the crafting activities are organized by the unit of workshop. Workshops are independent from each other and have independent business and advertising channel.

![Figure 2. People in the villages. Top left: the master is texting his client using an old phone in Guandu; Top right: Apprentices are working in the workshop in Guandu; Bottom left: villagers are playing ancient Chinese songs at the public space in Guandu; Bottom right: a teenager reading a book at the museum in Tengchong.](image-url)
Sanwa is an ordinary village—in the sense that it is not touristic place. It has been famous for embroidery for centuries. Unlike the other two villages, there is no public space for villagers to gather together. It is hard to see people engaging in craft making. Women were rather working at their home and making embroidery mainly for their families.

Tengchong is near the border of China and is well known for its traditional paper making. There, ancient life style and crafting practices are well preserved. Because of its uniqueness and the well preservation of the crafting heritage, a museum designed by a famous architect was built at the center of the village. The museum has attracted lots of attention inside and outside the country and is also a place for local people to socialize and discuss village issues, like the traditional paper business. The workshops at Tengchong are organized in family units—that is, each family has its own workshop.

Crafting as a Part of Living or Part of Culture

Crafting is deeply rooted in every aspect of the three villages, in terms of history, culture, economy and even mundane activities. Owing to these roots, the everyday activities of the village also strongly influence crafting practices. As such, these practices may be considered as intangible heritage.

Occupation versus Heritage Preservation

Among craftspeople, people have different understanding of what they are making. From the interviews, the young apprentices at Guandu took the crafting work as a normal job, while the masters considered the craft technique as heritage. The masters negotiate with local government to discuss the preservation of their crafts. For women in Sanwa, embroidery is just another job of theirs. Whether the craft is considered as commodity or heritage also influence craftspeople’s working environment, as it affects their income and the respect they receive.

Crafts: Commercialized & Artist Heritage

All the handcrafts observed required very complex processes to produce, involving sophisticated skills and tools. At a bronze workshop in Guandu, one month was the minimal time to complete a single craft object according to one craftsperson from the workshop.

Currently, there are two ways of viewing the crafts. One perspective considers craft as commercialized goods. For example, in Tengchong, some of the handcraft papers are used to create notebooks or other paper products and sold to stationery shops. The direct sales business model helps the craftspeople to earn a living and entails simplifying the making process in order to produce crafts more quickly. Another perspective regards craft as national heritage. In several workshops in Guandu, the craft traditions have been officially recognized as national heritage,
receiving government financial support for the preservation of the complex craft making processes. Crafts made in the traditional, complex way are naturally more expensive (Figure 3).

Figure 3. Left: embroidery in museum: The patterns are complex and the details require traditional, complex techniques. Right: embroidery in shop: An embroidery piece purchased from Sanwa. The patterns are simply flowers and plants which requires relatively less manual work.

Two Trade Models

From the observation and interviews in the villages, two trade models for traditional crafts can be identified (Figure 4). One is the Factory Model, as observed in Sanwa; another one is the Tourism Model, as observed in Guandu. Tengchong was observed to be in a process of changing from factory model to tourism model.

Factory Model

The factory model of craft leads to commodification of traditional crafts. Here, the production of crafts is profit-oriented. Craftspeople may regard themselves as workers who produce products, and associate little with their own cultural life and traditions. The importance of traditional cultural values embodied in the crafts may be diminished in this model.

Tourism Model

In the tourism model, crafts are considered as emblems of cultural heritage. In this model, the value of crafts comes from historic and cultural meanings. Since craft is integrated in local culture, local historical architecture and social activities are also integrated in the preservation of heritage. As observed, tourism helps to facilitate the exchange of values between villagers and outsiders.

No matter which model is used, there is a trend that younger generations have less and less interest in carrying on the heritage practice, as said by the curator of the museum, who is also the village head of the Tengchong village.
The Technology Embedded in the Crafting Life

Even in the most rural village of the three villages, technologies play some sort of a role in the whole process of traditional craft making and trading.

Technology as Making Tool

Tools—such as machines for drilling, sanding, sewing and so forth—are vital to the crafting process. Craftspeople rely on their skills and also on specialized tools. In contemporary society, technology has been integrated in the crafting process for a long time. The craft workshops visited all applied certain technologies to make crafting easier without diminishing the traditional ways of craftsmanship.

Technology as Communication Tool

The master craftspeople are the ones who keep contact with customers, government officers and other related people. The master craftspeople in Guandu and Tengchong all use cellphones for communications. Text messages were the main medium and none of them had a smartphone.

Technology as Advertising and Exhibition Tool

All the workshops visited have their own websites to exhibit the craft and the history of the craft, always created by people outside the villages. In the museum in Tengchong, a tablet was used to
display the making process of handcraft paper (Figure 5). The technologies acted as one-way medium and craftspeople have no knowledge about how to edit the content themselves. The tablet is used not differently than a video player and a television could have easily replaced it.

In general, all the technologies observed in the three villages are very basic and easy to use. ICTs help people outside the villages to know the crafts but the villagers have limited skills to fully utilize them for making, communication or advertising.

**Design Insight and Concept**

Our observation in the villages yielded three findings. First, at the community level, villagers seek to preserve craft and regard it as a carrier of cultural meanings. Second, under the influence of globalization, people in economically disadvantaged villages need cultural confidence to appreciate their own culture and heritage. Third, while the tourism model is better than the factory model, there is still room to improve social connections between villagers and the urban appreciators for exchange, support, and preservation of culture. With all of these observations considered, our design focuses on bringing cultural confidence to the villagers, through augmentation of the tourism model (Figure 6).
To achieve this goal, our design seeks to connect villagers and urban visitors who appreciate the village crafts, not only for selling crafts, but just as importantly for sharing traditional culture. Making craftspeople aware that others appreciate their craft yields incentives for them to take pride in what they are doing and thus build their cultural confidence.

Our interaction design concept system has two parts. One part is an interactive display installed at the public space at a village. Through simple interactions with the display, a craftsperson can have an overview of the distribution of the crafts made by him or her and receive tokens of appreciations from other places. The second part is an online platform that allows urbanites who have visited the village to have access to detailed information about the kinds of crafts they are interested in and send out their appreciation (Figure 7).
Physical Installation in Public Space at Village

Our design rationales are the following:

Considering villagers are not familiar with digital technologies, the control and interactions with the design should be simple and straightforward.

Craftspeople invest long working hours in making. Each craft piece can be considered as a unique and valuable piece. We want to foster appreciation for each craft piece and deliver the appreciation to the person who made the craft.

From the field work, we found out that public space is important in villagers’ lives. Public space is the place in which villagers participate and discuss public affairs, as well as enjoy group activities. It is also the place in which villagers discuss and make decisions about the village’s craft business and how to preserve craft practice as national heritage.

Therefore, our design specifies an ambient, public display in the village that shows where that village’s crafts are situated and being enjoyed once purchased by others. We call this the “Thank You Map.” The display would be installed at the public space in the village. For example, it would be in the public museum if it is to be installed in Tengchong. Each family in
the village has a large square button—we call it the “cube”—on the vertical surface of the display. When a cube is pressed, lighted and colored cylindrical bars raise from the horizontal map display denoting where that family’s crafts are now located. The height of the bars denotes the quantity of that family’s crafts which have found their new home at the location. Touching any of the bars triggers recorded “thank you statements” from people who own that family’s crafts and reside in the particular location denoted by the bar (Figure 8).

We hope by interacting with this display, craftspeople could have a straightforward understanding of how widely their crafts are appreciated. This representation and understanding about the value of their crafts can help villagers build confidence in their culture and craft practices. Furthermore, it can encourage craftspeople to treat their work as a continuation of a rich and historical heritage rather than a commodity revenue stream based on souvenirs. The installation could also be a way to attract tourists and inform tourists about the value of the local crafts and the value of these crafts as ongoing cultural heritage.

Figure 8. The concept. Top: The concept of the interactive installation at the village; Bottom: The online platform for people who purchase and appreciate the crafts.
Online Platform for People Who Appreciate Crafts

Our design specifies software for the people who appreciate craft as well. This part of the design is actualized as an online platform that provides detailed information about the crafts. A QR code or a craft number is associate with and attached to each craft piece. The person who purchased the craft can look up the craft on the online platform by means of scanning the QR code or inputting a craft number directly. Doing so uncovers information about the craft, including the name of the family who made the craft, village geographic information, as well as the history of the craft and cultural practices and contexts under which the craft was produced. The person who purchased the craft can also send out a voice message through the online platform. The voice message then can be stored in the physical display in the village and become one data point for the interactive components (Figure 8).

Our design calls for local or regional governments to sponsor and be responsible for the map, and we believe they will want to do so for the purpose of pride and preservation of cultural heritage.

Discussion

We presented design research to explore the space in which ICT can contribute to support for rural craftspeople and preservation of cultural heritage. Based on the findings from an in-depth field study of three rural places, we clarified our design goal and formed our design strategies. Given the current business model and diminishing heritage value recognized among villagers themselves and urbanites, one most important design goal is to foster cultural confidence among villagers and promote heritage value among urbanites. Our key strategy is to prioritize the needs of craftspeople, as we believe the heritage practitioners are the drivers of preserving and adapting traditional craftspersonship in today’s context. In reflecting on our research and design process, we see three implications that interaction designers who seek to design for preserving crafting heritage can consider.

Embed The Design into The Environment

According to Giaccardi (2001) and Giaccardi, Churchill, and Liu (2012), heritage is connected with space. It is “formed through a sustained yet day-to-day engagement with the materiality of the heritage object as well as with people's environmental settings.” (Giaccardi and Palen, 2008). From this field study, we also found that crafting practice, as cultural heritage, is closely correlated to the space in which it takes place. The space affects how people engage with heritage practices. Harnessing the current spatial structure and social customs of the village community and embedding the design into an existing social hub can help raise the collective awareness of the local heritage and also boost individual craftsperson’s confidence.
In addition, to support craftspeople and their heritage practice, it is not enough to only focus on the practice. As Cameron and Robinson (2007) writes, “heritage complex … [is] … "an institutionalized culture of practices and ideas that is inherently political, socially and culturally circumscribed.” The continuity of heritage practice needs support from many aspects of the environment in which the practice happens. These aspects include economy, policy and even the dynamics of the location. When designing for preservation of heritage and continuity of practice, it is important to take into consideration the underlying complex social structures.

Naturalize Interaction with Tangible Interface

In order for villagers to access the design without barriers, we believe tangible interaction is the most natural way for them to experience the design. Craftspeople and villagers are dealing with tangible objects everyday; therefore, we believe it is crucial to stay away from a purely screen-based solution.

Vary The Technology for Different Parties

One of the findings from the field study is that the technologies used in rural and urban places are very different due to users’ preferences and the availability of technologies. To connect these two communities, the design has to accommodate different technologies to provide the best experiences. For example, in the installation design, the interaction is as simple as pressing a button, while in our website design, we provided relatively more complicated interactions. One example of a more complex interaction is the system’s affordance of sending voice messages as opposed to text through the website to the tangible system located in the village.

Limitations

We used a design perspective to explore preservation of heritage and support for craftspeople. That is, we did design research in the villages, formed concepts, and created a prototype that specifies digital and interactive technology. The prototype shows promise. Nonetheless, to truly understand if this design can truly help, we would need to create the real world installation in the village. That is our future work. Some of the issues that need to be addressed beyond the prototype include how to engage local stakeholders, how to maintain the interactive installation in the village, and how to make sure the energy used for installation is sustainable with respect to the village’s limited resources.

Conclusion

In summary, we designed an interactive installation located at a village as well as an online platform to support communication between craftspeople and people who appreciate the craft, with the goal of fostering pride and confidence associated with crafts for the villagers and create a better sense of connectedness for them.
Our conceptualization is rooted in the findings from design field research. As Koskinen et al. (2012) point out, “[g]ood design research is driven by understanding rather than data.” Our research process strived to understand the targeted audience in their cultural and social context, through synthesizing notes from interviews, observations, and site visits. We came to realization that under the influence of globalization, people in these economically disadvantaged villages need cultural confidence to appreciate their own culture and heritage. We hope our design research could be one step towards focusing ICTs on the cultural wellness of rural people with respect to cultural heritage and preservation.

Acknowledgments

We would like to express our thanks to Professor Ming Xi Tang, Professor Duoyi Peng, Mr. Long for their generous help on this project. We also thank all our participants for their contribution.

Author Biography
Haodan Tan

Haodan Tan is a PhD student in Human-Computer Interaction design program at Indiana University Bloomington, US. Before the PhD study, she obtained her MSc of Psychology at the University of Glasgow and Master of Design at the Hong Kong Polytechnic University. With a multi-disciplinary background, her research interests lie in the cognitive aspects of computing and interaction design, with an emphasis on the creating emotional experiences between human and interactive system.

Huaxin Wei

Huaxin Wei is an assistant professor in the School of Design at the Hong Kong Polytechnic University, where she teaches interaction design and game design. Her research interests span across several fields including interactive storytelling, interaction design, game design and analysis, and human-computer interaction, with a focus on meaningful interactive experiences. Huaxin earned a PhD in interactive arts and technology from Simon Fraser University, Canada, and an MSc in computing science from University of Alberta, Canada.

Eli Blevis

Eli Blevis is Professor of Informatics in the Human-Computer Interaction Design (HCI/d) program of the School of Informatics, Computing, & Engineering (SICE) at Indiana University, Bloomington (IUB). He is also a Visiting & Adjunct Professor of Interaction Design at the Hong Kong Polytechnic University (PolyU) School of Design (SD). His primary area of research, and the one for which he is best known, is sustainable interaction design. His research also engages visual thinking—especially photographic foundations of HCI, and design theory—especially transdisciplinary design.
Graphic designers as cultural innovators: Case studies of Henry Steiner and KAN Tai Keung

Ilpo KOSKINEN, The Hong Kong Polytechnic University, Hong Kong, HK, ilpo.koskinen@polyu.edu.hk

Abstract

It is common to see graphic design copies of foreign models or other Chinese designers. These designers are apathetic toward the work and neglect its ongoing challenges, including the need for constant innovation. In contrast, there are masters who use Chinese culture in creative ways and achieve outstanding reputations all over the world. The reasons design masters choose Chinese culture as a theme for their graphic work and the unique ways in which they symbolise cultural resources and knowledge are explored and explained in this study. This study also illustrates how traditional culture can become a potential innovative strategy by applying a systematic and culture-based methodology. The case studies presented concern the first generation of graphic designers in Hong Kong: Henry Steiner and KAN Tai Keung. The preliminary results of the two case studies show very positive outcomes for cultural interpretation becoming a new innovative stream of graphic design.

Keywords: Innovation, design masters, culture interpretation, graphic design

It is common to see Chinese graphic designs that are copied directly or indirectly from foreign designers or other Chinese designers. However, some successful designers use their culture resources in creative ways and establish unique identities through their graphic work. One of the main problems facing Chinese designers and design educators is that they seem to treat the cultural heritage of China as a marginalised resource and ignore that many internationally successful designers have strong identities of their own, as evidenced by their design work or research methods (Jian, Jie, & Taikeung, 2005). Understanding their own cultural origins and directly or indirectly using their cultural heritage in design is an essential quality of these internationally established designers (Lu, Etzkowitz, Lu, & Etzkowitz, 2008; Xu, Smith, Bower, & Chew, 2004).

As these graphic design masters always create successful artwork, winning them excellent reputations within the design community, they are also recognised by customers who realise the commercial value of their work in the marketplace. Hence, the way they interpret Chinese culture in graphic design can be instructive and meaningful to others. Graphic works can be empowered by traditional culture-based design, which is the hypothesis of this research. The reasons the masters choose Chinese culture as a theme for their designs, and the effective ways in which they symbolise their cultural materials, are explored. However, although the design masters are successful at finding inspiration for their design work, it can be difficult
for them to
explain how their design processes are explicitly formulated, given that their ways of working are characterised by independent styles that can be surprisingly simple or sophisticated to others. As mentioned in Summatavet (2005) study, informants, artists and bearers play different roles, making it impossible for a designer and a researcher to think alike. This study puts forward a series of related issues from the designer’s point of view. By deeply engaging designers through interviews and analysis, supported by careful studies of their backgrounds and the progression of their professional careers, something of value is revealed. The wisdom or style of the designers is then presented and generalised as understandable knowledge that can help others in their design studies or practice. The objective of this study is to develop a framework that is intended to showcase how traditional culture may become an innovative strategy. The cultural inspiration and design philosophy of the master designers skilled in cultural interpretation can provide a good lesson for young designers.

**Designers as innovators of culture**

**Finding previous innovation**

In his book *Diffusion of Innovations*, the American communication theorist and sociologist Rogers (1962) proposed a theory that attempted to explain how and why new ideas and technologies spread. Initially, in people’s minds, ‘innovation’ existed only in science, chemistry, biology and physics for the purpose of making discoveries. However, in the 1980s, technology-based innovation began to play a greater role, as MIT professor Utterback (1994) mentioned in *Mastering the Dynamics of Innovation*. Many studies have shown that technological innovation can have a positive effect and improve the competitiveness of enterprises (Dierickx & Cool, 1989; Guan & Ma, 2003). Nevertheless, Garcia and Calantone (2002) argued that innovation differed from invention in that it provided economic value and spread beyond the discoverer. Although they still rely on technical or scientific innovation, innovative business models can create new markets and allow companies to devise and exploit new opportunities within existing markets (Amit & Zott, 2012). Closer to design, Heskett (2002) proposed that utilitarian dimensions involved function and performance, and equally importantly that dimensions involved signs, identities and emotions – in other words, meaning.

**Designers as innovators of meaning**

The most important statement on innovation in the design literature was probably made by Verganti (2009), who insisted that its two major forms were radical and incremental innovation. Verganti used different case studies to demonstrate the implications of design-driven innovation in technology and design (Figure 1), such as that found in comparative game development companies such as Sony, Microsoft and Nintendo.

As Verganti’s work was essentially based on the Italian design of the nineties, rather than the general point of view of the world, it was hardly applicable outside of that context, and the scope of its innovation was limited in its explanatory power. The emergence of innovative methods in different times and fields has enriched researchers’ thinking to a great extent. However, there remains no clear answer to graphic design innovation, and some concepts in
graphic design cannot be explained in terms of science, technology, business models or new meanings.

Therefore, how graphic designers innovate and become inspired is further explained and explored in this study. These doubts and blank areas have evoked the curiosity of the researchers who wonder whether cultural interpretation could be a new stream of innovation in design.

![Figure 1 Technical innovation and meanings](image)

Contemporary method of innovation

Culture is an important part of design innovation. Csikszentmihalyi (1999) stated that design was a knowledge- and skill-intensive creative activity. Creativity is understood to take place at the intersection of individuals and culture or symbols within the social sphere. Part of Linder (2014) thesis on the social, material and cultural environment located in design work showed an interaction between design activities and their social and cultural backgrounds. Specifically, in graphic design, the goal of the graphic designer is to produce clear communication (Frascara, 1988). In other words, based on the preceding statements, cultural background is conducive to a better expression of graphic design work.

The designer's role in culture-based innovation

Two main references focusing on the transformation of traditional culture in creative ways come from Xin (2006) and Summatavet (2005). Xin’s goal was to develop a method that could be applied to Chinese product design and development. With his rich design and education
experience, Xin insisted that it was not easy for a designer who had not majored in cultural history or related cultural research to integrate fantastic cultural elements into design.

Kart Summatavet is a jewellery designer whose work can be found in both private collections and museums. With the disappearance of the traditional costume, dependence on museum collections has become the norm. However, fieldwork as an ethnographic method has given Kart as an artist the opportunity and confidence to follow new paths in her work. The knowledge she has obtained in the field has triggered a deeper interest in the bearers of tradition. She has pursued ethnographical and anthropological disciplines in her research. According to Lévi-Strauss (2008), ‘the aim of [the] ethnologist is to try to put himself/herself in the place of the people from another culture, to understand the essence and the rhythm of their aspirations, to comprehend an epoch or culture as a meaningful whole’. Summatavet (2005) used a chart (Figure 2) to show how she as a designer studied and applied the cultural essence of a traditional folklore artist.

Figure 2 The bearers of tradition and user groups (Summatavet, 2005)
The theoretical framework: The designer as an interpreter of culture

Designers are important to the study of culture-based innovation, and the design masters were interviewed and learned from in this study. These masters were superbly professional, and their design methods and inspiration were more significant than those of the average designer.

An inexperienced designer may simply follow the basic rules of design to meet his or her customers’ needs without achieving any unique goals. However, it is difficult to study and explore the design philosophy hidden in successful design work without a deep understanding of the designer. Hence, the researcher plays the role of an informant, using theoretical methods to transfer knowledge from different aspects of successful designers (Summatavet, 2005). From the designer’s point of view, putting forward a series of research-related issues (Error! Reference source not found.), for instance, can determine whether traditional culture can be used as an important element to strengthen the visual power of a work. Whether designers can use visual language to express how they derive inspiration from tradition depends on how they weigh the relationship between tradition and modernity or new technology. It is the main objective of this study to understand the details of the design masters’ work in addition to their ways of thinking to learn how they have made breakthroughs in their evolution from tradition to modernity.

Figure 3 Theoretical framework of the case study
Methodology

Research methods

Elite interviewing was the main method used to collect data for this study. Most of the literature on elite interviewing has come from the social sciences. The best-known studies have dealt with lawyers (Smigel, 1958), businessmen and politicians (Jackall, 1988; Robinson, 1960). In design, elite interviews have been a typical component of studies mapping problem-solving techniques (Dorst, 2015). Meanwhile, to understand designers, it has been important to capture the physical and visual things within their working environments through photographs. The photographs of Henry Steiner’s collections of souvenirs and memorabilia have proved to be important to understanding how he thinks about the culture of China (Figure 4).

Figure 4 Displays in the office of Henry Steiner and his poster

Interviewing was not the only approach used to understand the design masters. The collection and analysis of secondary materials was equally important to this study. One characteristic of the elites is that they produce an abundance of secondary material that can be gathered during the preparation phase. They write books and columns for newspapers, give interviews and have typically been studied before (Mykkänen, 2001). The elites know their value, and this is something the researcher must think about when preparing for interviews (Kincaid & Bright, 1957; Searing, 1994; Zuckerman, 1972).

After collecting the data, the main method of sorting and coding took the physical form of a data box (Figure 5). All of the data from every interview were placed into a big semi-transparent box, which was divided into sections to decompose it. The upper left corner was reserved for clips from artwork and secondary materials, and the lower left side was used for photographs. The right side contained the interviews, and various memoranda written by the researcher were set forth below them.
The guidelines used for this box comprised colourful flags and numbers (Figure 6). Following the initial analysis, codes were generally divided into two groups: design philosophy and factors in design work. The codes grounded in the requisite data were proposed by Glaser and Strauss (2009).
This study had several inbuilt validity checks to verify the selected interviewees and the interview questions and answers. Most importantly, this study used several means of data collection and analysis, known formally as triangulation (Denzin, 1978). This is a powerful methodology that helps validate data through cross-validation from two or more sources (Bogdan & Biklen, 2007).

**Analytic induction**

Designers from different parts of China were listed based on an initial analysis. Pilot studies were then conducted in mainland China, Hong Kong and Taiwan. Each study, as shown in Figure 7, included interviews with the designers together with a comparison and analysis after two or three interviews had been conducted. Pursuant to the analytic induction method proposed by Koskinen, Battarbee, and Mattelmeaki (2003), constant comparisons were made through a small group of cases, coming from interviews with five design masters in Hong Kong.

Following the hypothesis, i.e., that there would be no correlation between a designer’s cultural interpretations in different regions, the analysis was based on comparisons between Hong Kong, mainland China and Taiwan. Comparing the results from the Hong Kong designers, as shown in Figure 7, was the first step towards testing the initial hypotheses in mainland China and Taiwan, respectively. The initial research addressed the relevance of the position and method of the designer’s cultural interpretation in one place and the constant comparison between the differences of the designers. If more negative cases were found in testing the preliminary hypothesis, to avoid future ineffective efforts and subjective concepts, an additional hypothesis based on the first two critical interviews, with Henry Steiner and Professor KAN, were tested. If not all of the respondents regarded cultural elements as their most important inspiration, the cultural interpretation of the creative design related to the location of the designer, some external
factors, teacher relations, design philosophy, customer and marketing needs, educational level or
growth background became additional hypotheses, and the researchers combined the results of
the two assumptions in the outcome of this study.

Guiding assumption

Exploring how famous Chinese graphic designers interpreted Chinese culture and used it in their
work, and determining what explained their innovativeness, were the focuses of this study. Based
on a literature review and an initial analysis of the designers in Hong Kong, mainland China and
Taiwan, several of the guiding assumptions are listed as follows.

- Culture could be a significant inspiration to arouse a designer’s innovation.
- There was no direct relationship between a design master’s method of cultural
interpretation and his or her location.
- Their design philosophy, teacher relationship, growth background and working
environment influenced the master designers’ way of innovating.

Case study 1 - Henry Steiner

Background analysis and his design concept

Henry Steiner was known as the king of graphic design in Hong Kong, and his work could be
seen everywhere. It stared at the public from billboards, banks and other buildings, and even
lurked in their pockets. Steiner was born into a middle-class Austrian Jewish family in 1934, and
after years of study and work in New York settled in Hong Kong for nearly 60 years. His long
and stable career in Hong Kong allowed him to establish his design philosophy as part of the first
generation of Hong Kong graphic designers. Based on what he learned from Paul Rand and his
long professional experience, Steiner represented the view of cross-cultural design. In the book
Cross-cultural design: Communicating in the global marketplace (Haas & Steiner, 1995),
Steiner received a detailed elaboration. He insisted that most people did not know their culture
because they were used to thinking of oxygen, evolution or gravity when it came to discussing
the foundation of survival. ‘Culture is our environment; it is the “natural” way of thinking and
acting, as a fish in the water’, he said. According to his book, combining the designer’s
perceptions with the target audience’s understanding of life’s fundamental issues (time, religion,
family relationships, gender, technology, politics and economics) could present an exciting
combination of effects and differ greatly.

Through his interview, it was easy to understand not only his views on Hong Kong, but also his
views on the places he had stayed before coming to Hong Kong, especially in terms of their
customs and designs. During the time he studied in Paris, for example, he developed a much
more European sensibility that influenced the body of his work. At the time, London, New York
and San Francisco were well developed in terms of the design business; however, those places
were not considered special enough to settle in and develop a design career. Again, it seemed
Steiner was looking for a career and a life with contrast.
The formation of his design philosophy: Contrast

Steiner’s design strategy of ‘contrast’ could be seen in his posters, branding and banknote designs. It was one of the things he learned from Paul Rand. The strategy was especially strong in the early days of his designs, and he subsequently made many comparisons, including quite a few for Asia magazine, wherein he would present something Western and something Eastern, contrasting them with each other. On the surface, it appeared that Steiner simply put Western and Eastern design together. However, as he used a classic concept and an approach that people had not tired of, we put it up for close examination from a philosophical and technological point of view. When a design is cross-cultural, it is important to remember that it is not a question of right or wrong, or better or worse. The goal is to achieve a harmonious concatenation, with more interaction than synthesis. Each element should be preserved, as this maintains an object’s original identity while enriching it through another’s, like balancing yin and yang. The underlying core idea resembles Taoism, but it is different from the ideas of Professor KAN and other designers. Steiner said he did not view it as a mixture or a blending; he wanted to preserve the integrity and independence of each cultural element. According to him, contrast was not only reflected in cultural differences, but also manifested in forms of expression, concepts and so on. As his banknote design in Error! Reference source not found. shows, this was a basic view Steiner held, and reflected what he meant by contrast. Designers can become artists by saying and showing people something that they know and something that they do not know.

Figure 8 Henry Steiner’s banknote design, which shows ‘contrast’
Case study 2 – KAN Tai Keung

Background analysis

Professor KAN Tai Keung was proficient in traditional Chinese culture and philosophy, given that he was born in mainland China and learned about Chinese art from his family. In addition, he had two teachers, WANG Wuxie and LV Shoukun (the former of whom had an overseas education), who taught him more advanced graphic design. His work had influenced at least two generations of Chinese graphic designers. Furthermore, his artwork had been recognised all over the world, and as he travelled the world, more and more new design concepts came to him, including some from Western culture. Hence, in addition to achieving an international standard, his work contained rich Chinese philosophical connotations, which resonated with the Chinese and distinguished him from foreign designers. KAN insisted that a culture without philosophical thought was like a person without a spine, and could not stand up and face the world. Although he mentioned during his interview that it was not necessary to interpret Chinese culture in design by using Chinese objects, the artistic style and representative design elements frequently used in his artwork suggested his addiction to Chinese culture and philosophy.

Figure 9 Collections in KAN Tai Keung’s office

KAN Tai Keung’s previous experience as a tailor unconsciously motivated him to use a ruler as a visual language tool, and learning Chinese ink painting from childhood contributed to his frequent use of four other elements: red dots, water, ink marks and tools in ink painting (Figure 10). Compared with Henry Steiner, who settled in Hong Kong for nearly 60 years, the Western part of Kan’s artwork could not be totally replaced by Eastern culture.
The relationship between design philosophy and Chinese culture

In Chinese traditional culture, Confucianism, Buddhism and Taoism are three of the main philosophies. Every educated Chinese person has been taught on the basis of these three ideas. If the basic idea of in-depth understanding is lacking, and people pass through the concept of design as if fishing in the air, their efforts will be futile in the end. Buddhist thought has spread from the western to eastern regions. Buddhist philosophy is the epiphany of life. All the world is illusory, pain and happiness, which comprise the mystery of feelings. If we can see that ‘the form itself is emptiness; [and] emptiness itself is formed’ truth, we can look beyond life and death to ‘great freedom’ (Rāhula, 1974). In KAN’s work, ‘free’ pattern paper was a kind of paper with Chinese cultural significance, which he created for Nippon Paper House. The philosophy of Buddha’s ‘great freedom’ comprised the origin of this work. In Chinese art paper, the use of handmade paper edges and bamboo texture constitutes the landscape of natural artistic conceptions that reveal the Chinese light-heartedness and a calm attitude.

Taoism is the master of the universe. Life is divided into yin and yang, representing all of the derivatives of life and growth in nature. All people and things are symbiotic and go with the flow to obtain harmony between heaven and earth (Weber & Gerth, 1953). In the relationship between man and nature, there is a fundamental difference between Eastern and Western philosophy. In the West, especially since the Renaissance, humans have been regarded as the masters and even controllers of nature, resulting in the rise of the industrial revolution and a variety of outstanding scientific and technological inventions. In the East, however, humans have often been viewed as a part of nature, continually seeking to reconcile with it. To KAN, we were a Western-dominated and highly competitive consumer society, often lacking in comfort and the Oriental philosophy instilled by the peaceful and quite mind to make up for this deficiency. KAN wanted his designs to give the public a feeling of stability. The three philosophies (Confucianism, Buddhism and Taoism) have many commonalities, yet each is a unique system of thought. Their ideas have far-reaching implications for every Chinese person. Therefore, as a Chinese designer, KAN’s works were inevitably influenced by these philosophical ideas, trying to show the attitudes of the Chinese people towards life (靳埭强, 2004).
Emerging hypothesis

The definition of design in this study was inspired by the design masters. It can be called culture-based innovation from the perspective of the designers’ cultural cognition, cultural interpretation of design work and external influencing factors (Table 1), such as exotic growth experiences and different cultural backgrounds. All of these elements have been more or less ascribed as important by people such as Steiner, who credits them for his international recognition. Alternatively, traditional Chinese philosophy, Buddhism, Taoism and Confucianism or the concept of harmony between man and nature have had a great effect on KAN’s harmonious design ideas, which are full of Chinese flavour. The unique philosophical ideas underpinning his work in the design field are unique. Together, the case studies of Steiner and Kan represent the breakthrough in graphic design innovation.

The interviews with Steiner and KAN were very productive. Both men played crucial roles in the world of graphic design, representing the first generation of world-famous graphic designers in Hong Kong. The interviews were carried out in their offices. The experiences gained and the visual information collected from their work spaces gave the researcher great inspiration and the energy to conduct a deeper analysis of their thinking and design approaches to graphic design within their cultural understanding. The data collected from these interviews, their lectures, and the secondary materials were sorted into boxes to prepare for constant comparisons (Glaser and Strauss, 2009). This provided further inspiration to promote the primary hypothesis, i.e., the factors affecting innovation in graphic design. The preliminary interviews led to some emerging hypotheses.

- Design masters have their own unique design philosophies that persist for many years; however, in the actual design of a project, other factors may be given primary consideration, such as the needs of the customers or the market.
- A designer’s educational experience and growth background form the foundation of the design philosophy that is hidden in his or her artwork. The working environment, collections, relationships or personalities all have reference value for studying how designers are inspired.
- Culture is a situation-specific source of a designer’s innovation, and its role is located in and built on by the nature of the work.

The data collected from the two masters’ interviews were based on their decades of working and communication experience. However, marketing trends or customer needs cannot be ignored in some real projects. Sometimes, these factors must be considered and given the primary position in graphic design projects.

Discussion and Conclusion

Contributions

The contributions of this study are not easily evaluated, as every designer acts independently and has different thoughts and aesthetic standards. It is impossible to say whether the framework of this study could be applied to help all designers; however, it may affect or provide some inspiration for new designers. Innovation, as the embodiment of design concepts, enables a designer to express his or her internal thoughts to the external world and attract more customers for the sake of enlarging the effect. The new stream of cultural innovation explores a blind field, where customers find it hard to know the reasons why they are moved by art and gain resonance from it. In terms of design, it helps to draw a clear map for designers to know how they gain inspiration, and why the master designers’ innovative work wins them excellent reputations all over the world. For society, the categories of innovation are continuously updated and their scope is further expanded.
Future study

The next stages of this research will involve a focused approach to further define the constructs of innovation, the meaning of culture and the tension between tradition and innovation for the design masters. All of the designers who will be interviewed have been listed before, based on the initial analysis of secondary material. The interviewees will be further identified when their interviews are conducted. Case studies will involve interviews with these experts, visiting their studios and becoming more familiar with the design concepts in Hong Kong, mainland China and Taiwan. In addition, more interviews will be carried out with masters such as Steiner to consolidate the findings and develop more substantial thoughts based on analysis of the data collected. This information will be instrumental to further developing the proposed framework and defining how the masters of graphic design interpret the Chinese culture, what format the designers’ philosophies take and what explains their ability to innovate. Conducting structured interviews will allow the researchers to ask specific questions related to this study, the definition of culture in design and the strategies for interpreting Chinese culture in design.

TIAN Yao

TIAN Yao, Yolanda was born in northern China. After graduating from the Academy of Arts in Nationality University in Beijing, she worked as an E-zine designer in China Film Press based on her major graphic design at the time when the interactive magazine had just begun to emerge in China. Then she got her Master degree on Multimedia and Entertainment Technology in the School of Design, Hong Kong Polytechnic University in 2014. During the time in PolyU, her interest and passion for researching design thinking process was ignited through several projects
on interactive design, user experience, as well as business management. After one-year working in Sino United Publishing (Holdings) Limited in HK, she came back to PolyU, as a PhD student.

During the PhD study, her research topic is ‘How masters in graphic design interpret Chinese Culture?’ This research topic directly addresses the issue of lacking of innovation of graphic works among Chinese designers, and emphasizes on the importance of cultural factors in the design process by the application of a systematic and culture based innovation methodology (Jian et al., 2005).

Ilpo KOSKINEN

Ilpo Koskinen specialised in design research, where his main interests have been in mobile multimedia, social interaction, and methodology. Usually interested in emerging ideas, his work concentrates on the avant-garde end of technology and methodology. He is professor, an experienced teacher, project leader, and thesis supervisor especially at MA/MSc and doctoral levels. He also functions as an editor, his most recent book was well-received "Design Research through Practice," published by Morgan Kaufmann. He has published well over 100 papers, conference papers and books.

His main areas of expertise are:

- Research methods especially qualitative, empathic, and constructive
- Consumer studies especially studies of design when it enters everyday life
- Mobile multimedia especially visual means of communication
- Information technology especially co-experience and proactive technology

In addition, he has studied formal organisations, design in urban space, education and sustainability, and world design. Lately his writing has been mainly critical.
A Study on the Entrepreneurial Path of Design-led Startups in Taiwan

Fang-Wu Tung Department of Design, National Taiwan University of Science and Technology, Taipei, Taiwan. fwtung@mail.ntust.edu.tw

Abstract

The phenomenon of design entrepreneurship has received attention in the field of design. The trend of design entrepreneurship emerges in Taiwan and becoming a new career option for designers. Entrepreneurial activities can promote economic growth through innovation and knowledge spillovers. Studies on designer entrepreneurship are warranted because it proposes the possibility of entrepreneurial innovation, contributing to industrial and economic development. A multiple case study was employed, and seven design-led startups were selected as case study subjects to explore and conclude how these firms integrate their own profession and acquire resources to construct the value chain so as to keep the company operational and profitable. According to the results, the value chain of design-led startups is identified. The findings are further discussed to provide a better understanding of the entrepreneurial path of design-led startups in Taiwan.

Keywords: design entrepreneurship, value chain, design-led startup

Introduction

Entrepreneurship that helps promote economic development is currently receiving increasing attention, and many countries consider encouraging entrepreneurship as an effective approach to promote economic and social development. Ridley (2010) indicates that entrepreneurship is a crucial thrust to stimulate economic growth and envisions that economic development will be led by small businesses in the future. The shift from a “management economy” to an “entrepreneurial economy” since the mid-1960s has influenced firm size and market rules. In an economic system that emphasizes knowledge and creativity, many small and medium-sized enterprises (SMEs) have been emerging with their creativity and knowledge (Audretsch & Thurik, 2001). The use of information and communication technology helps enterprises collaborate in nonhierarchical networks, enabling many startups to organize and engage in innovative activities on their own (den Ouden, 2012).

Design entrepreneurship involves creating businesses and new opportunities with the help of design processes. Any designer who runs a studio, office, or firm can be considered as entrepreneurial. In this study, design entrepreneurship is about producing and marketing the intellectual properties of a viable concept in terms of assuming risks, financing, and managing (Gunes, 2012). In the past, designers established design studios to provide clients with design services. They rarely established their own brands and put their design ideas into production, marketing, and sales. With an increase in the entrepreneurial trend, several designers not only provide design services but also start businesses to sell products they have developed. Tom Dixon, a London-based designer, exemplifies a design entrepreneur. In addition to product design, Tom Dixon is involved in production, distribution, and consumption systems. The expansion of designers in the areas of production and marketing suggests that a new role of a design entrepreneur is taking shape. Some design-led startups were formed and targeted the international market; these startups are termed as “design-intensive born globals” by Falay, Salimäki, Ainamo, and Gabrielsson (2007). According to a
study on six design startups in Finland, they report that these young and small startups were located in the international market, mainly because the domestic market was too small to grow those design startups. Regarding the marketing strategies, the cost of traditional advertising methods is excessively high for the startups. Hence, the design startups in Finland expose and market their products through participating in international trade shows. A similar entrepreneurial path can also be found in design startups in Taiwan. According to the Taiwan Cultural and Creative Industry Development Annual Report in 2013, an increasing number of designers start their own business. In Taiwan, design students were previously aware of only two career paths: design consultant or corporation designers. They seldom considered using their design skills to become entrepreneurs. However, currently, being a design entrepreneur has become one of the career options for design students.

Flexibility is an advantage of small businesses. Small businesses can rapidly adapt and respond to changes in the market. Countries with more small businesses and entrepreneurial activities have higher economic growth rates and lower unemployment rates (Thurik, Audretsch, Carree, & van Stel, 2008). In entrepreneurship-related studies, most researchers pay attention on to technology- or information-oriented startups, focusing on issues regarding management, economics, or entrepreneurship. However, less attention is paid on design entrepreneurship. The capability of combining concepts with manufacturing to develop new products and launching them into the market has become the entrepreneurial model of designers. Entrepreneurial activities can promote economic growth through innovation and knowledge spillovers. Studies on designer entrepreneurship are warranted because it proposes the possibility of entrepreneurial innovation, contributing to industrial and economic development.

Literature review

Design Entrepreneurship

The phenomenon of design entrepreneurship has received attention in the field of design (Vienne, 2002; Heller & Talarico, 2008). Most industrial designers have fantasized about designing their own products and getting them into the market. However, being a design entrepreneur means that the designer should be involved in activities such as raising money, lining up manufacturing, and getting publicity. In the past, these entrepreneurial activities were difficult for designers. Nevertheless, some factors make it relatively easier for designers to transform a product concept into a viable business (Furbershaw & Herbst, 2013). Internet tools and resources create an environment that allows self-learning, immediate production, accelerated collaboration, and rapid networking. Crowdfunding platforms allow designers to access funding and develop a customer base. Product reviews from Internet media, such as web magazines or blogs, can gain publicity for a new product. We encounter a rapidly changing environment characterized in particular by new technologies and globalization. These changes also provide opportunities to designers to become entrepreneurs. Bianchini and Maffei (2012) indicate that the following four changes provide opportunities to designers to start their businesses. 1. Industry is changing: Manufacturing interdependence and outsourcing are the norms in the contemporary industry. The miniaturization and digitization of production technologies allow SMEs to overcome the local production capacity and geographical limitations, entering the global network. 2. Places of production are changing: Self-made production trends change the sites of production; the studio, workshop, and laboratory can be used as a production field. This allows designers to integrate product design, production, and distribution. 3. Product/service
is changing: More products contain a combination of hardware and software, leading to a complicated relationship between design and artifact production. The rapid product/service revolution is a new area for all manufactures; therefore, innovative entrepreneurs have the opportunity to win in the market. 4. The market is changing: The more mature the market, the more diversified the consumer demand. The change in the market provides startups an opportunity to develop products targeting on niche markets.

There are some commonalities between the entrepreneurial process and the design process, both of which attempt to propose new ideas and create better solutions (Zhou, 2008). Morello (2000) indicates that design is a future-oriented activity. Designers envision how people use and respond to new products or services. Similar to the new product development process, the entrepreneurial process must be close to the society and take all stakeholders into consideration. Creativity, the design profession, and empathy for the customer are the strengths for designers to become entrepreneurs. However, the development of the business process does not only propose the concept of a product but also complete a business model (Pavia, 1991). Entrepreneurs must take action to turn ideas into viable business ideas (Dimov, 2007). Design entrepreneurship reflects the possibilities of a designer's potential to innovate in the creative economy, transforming design concepts into business ideas (Cardozo, 1986). The expansion of these areas of expertise and the formation of new roles are challenges that designers must overcome to transform into entrepreneurs.

**Value Chain**

The management of design-led businesses requires skills in both the entrepreneurial and design aspects of the business operation. From a designer to an entrepreneur, design entrepreneurs not only serve as creative producers but also have the ability to turn the product concept into commercially viable products or services. The series of activities that an organization performs to create value for its consumers is known as the value chain, as proposed by Porter (1985). The value chain represents the internal activities a firm engages in when transforming inputs into outputs, where initial creative ideas are combined with other inputs to be produced, enter marketing and distribution channels, and eventually reach the consumers. The value chain can be used as an analytical tool to analyze activities through which firms can generate value and a competitive advantage. Entrepreneurs should understand the value chain in industries and the roles and responsibilities of players at each stage of the value chain.

The application of the value chain is not only suitable for enterprises with a scale but also applicable to SMEs (McLarty, 2005). Landry (2000) applies the value chain to cultural industries and generally classifies the following five stages: beginning, production, circulation/distribution, delivery mechanism, and audience reception. The United Nations Conference on Trade and Development (UNCTAD) applies the value chain to creative industries as a series of processes, encompassing four different stages: (a) creation/conception, where the development of an idea or concept takes place; (b) production/reproduction, the stage at which an idea or a concept is developed further and then packaged; (c) marketing and distribution; and (d) consumption (UNCTAD, 2010). For design-led startups characterized as small or micro-sized businesses, they can carry out only one or more stages of the value chain. Thus, the design-led startups must integrate or collaborate with different skill groups to complete the chain.

Analyzing a business from the perspective of the value chain, researchers should focus on
what item has to be accomplished and how the resources should be used to accomplish such an item (O’Sullivan & Geringer, 1993). For design entrepreneurs, the concept of value chain provides them with a comprehensive perspective to understand how to integrate upstream and downstream and internal and external resources to add value to their products. As the environment and industry changes, the value chain also has different forms of links. Shane and Venkataraman (2000) argue that entrepreneurship is the examination “of how, by whom, and with what effects opportunities to create future goods and services are discovered, evaluated, and exploited.” Design entrepreneurs are an emerging phenomenon in Taiwan. The development of the entrepreneurial process varies from country to country because of different resources and market sizes. Value chain analysis can be used to understand how design entrepreneurs discover opportunities and capitalize on the available resources and advantages in Taiwan to start design businesses.

**Research Method**

This study adopted a case study method to execute the exploration. The case study method enables in-depth, multifaceted explorations of complex issues in real-life settings, enabling researchers to understand the development of the incident and related factors through exploring why and how the current situation is formed (Ragin & Becker, 1992). A multiple case study was employed, and seven design-led startups were selected as case study subjects to explore and conclude how these firms integrate their own profession and acquire resources to construct the value chain so as to keep the company operational and profitable. The selected case subjects and interviewers are listed in Table 1.

The data collection process involved collecting primary and secondary data. Primary data were collected through a questionnaire and an interview with the founders of the selected firms. The questionnaire and interview focused on four aspects of the value chain: 1. Design creativity, 2. production, 3. marketing/distribution, and 4. consumption. Secondary data were collected from different sources such as articles, records, books, reports, and Internet. All data were analyzed using framework analysis, starting from a framework of four higher-order codes that represent the four stages of the value chain while inductively searching for subcodes that reflect activities of each of these stages in the specific context of design-led startups in Taiwan.

**Results and Discussion**

According to the data analysis, the value chain of design-led startups is shown in Figure 1. In general, most of the design-led startups started with one short product line consisting of only few products. For design entrepreneurs, their skills and talents that enable them to conceive product ideas and prototype their products constitute the starting point of their businesses. These products will not proceed to the production stage directly until they
receive orders from buyers. Before moving on to the production stage, design entrepreneurs need to gain exposure for products in order to receive orders from buyers and confirm market opportunities. Thus, the value chain is not a linear process, as shown in Figure 1. The early exposure stage is necessary to facilitate the value chain of design startups. Design entrepreneurs should learn how to capitalize on resources and collaborate with others to complete the value chain from upstream innovation to downstream commercialization. As C3 respondents mentioned, “A design entrepreneur must have integrated talents and should not just be a designer. Design entrepreneurs must have an integrated ability in which they should know how to integrate the available resources to work out a viable business.”

Figure 1. Value chain of design-led startups

**Design creativity**

Creativity is a vital factor in the discovery/creation of entrepreneurial opportunities. Conceiving a creative idea of a product does not guarantee success for a business. The key to the success of micro or small businesses is finding and choosing a niche market. All participants pointed out the importance of recognizing or creating a niche for a product. Focusing on a more specific and smaller area of the target market is often the better approach for a small business. Thus, design startups can demonstrate a clearer and precise image to clients, prospects, and referral sources. In this study, products developed by the design startups can be mostly classified into two categories: accessories and home & living. The accessory and home décor markets are mature and fragmented, comprising several submarkets. The fact that consumers pursue uniqueness in self-image and home environment gives opportunities for design entrepreneurs to create unique products to satisfy the market needs. One the designers contribute to the market success is the design of product appearance especially in the situation when it becomes harder to compete on functionality and technology. In the mature market, design is recognized as a strategy to differentiate products from those of their competitors. According to this study, the design entrepreneurs make their products niches by focusing on one of two areas: esthetic or style and material.

**Production**

Design-led entrepreneurship does not mean self-production. In this study, only case C adopts self-production to produce their products made from concrete. Most of the design startups commission or collaborate with factories to produce their products. The manufacturing industries in Taiwan allow design entrepreneurs to access locally available manufacturers, facilitating the process of prototyping, making samples, and production. The
unique features of products pose challenges for designers to put the design concepts into production. They have to collaborate with manufacturers to develop feasible methods to produce their products at a reasonable cost. In this study, we identified three types of production that design entrepreneurs adopt to realize their concepts: mass production with craft practices, modern craft-making, and self-production.

Cases A, B, and G use mass production with craft practices to produce their products. For example, products made by case B (Figure 2) are actually produced through injection molding, a common mass production technique. To obtain delicate and handmade-like products, it requires ad hoc adjustments by humans to make a fine product. The flexible production enables design entrepreneurs to maintain the esthetics and uniqueness of their products. The modern craft-making process allows cases D, E, and F to create products with some materials such as bamboo, ceramics, brass, and paper (Figure 3). Unlike the traditional craft-making process, design entrepreneurs need to collaborate with craft factories to develop a feasible production process or introduce modern tools that can improve their manufacturing capacity and reduce costs. Thus, design entrepreneurs have to take production into consideration while developing new design concepts. With regard to self-production, case C uses concrete as the main material to create stationary items, jewelry, and timepieces (Figure 4). The use of three-dimensional printing technology and silicone modeling allows case C to produce products on their own.

**Marketing/ Distribution**

In the stage of marketing/distribution, attending exhibitions or trade shows is one of the propaganda strategies adopted by design entrepreneurs. Because of the small size of the domestic market in Taiwan, the design-led startups have to market their products in the international market. International trade shows or exhibitions provide them opportunities to sell and promote their products internationally and enter the international value chain (Browning & Adams, 1988; Measson & Campbell-Hunt, 2015). Despite having limited in their resources, the startups tried to look for resources from outside to participate in exhibitions, either to apply for government grants or to participate in joint exhibitions with their peers.
In addition to exhibitions and trade shows, the Internet provides startups an inexpensive means to expose products. Many startups primarily sell products through crowdfunding and online stores, reaching consumers directly and learning about their feedback. The founders noted that their firm would not exist without the Internet. Through the Internet, they can reach people scattered around the globe. Digitization and networking change the production and distribution method. An emerging global marketing structure is also changing the manner in which goods are sold. Online shops or platforms, such as Etsy and Pinkoi, enable design entrepreneurs to have more channels to sell products to consumers directly as well as build a network of interested consumers. In this study, many design entrepreneurs had run crowdfunding campaigns in Taiwan or in the United States. They considered crowdfunding as a means of obtaining funds and understanding market reactions and marketing methods. The impact of the Internet not only on marketing and sales channels but also on the acquisition of resources and capital, product development, and establishment of customer relations.

Conclusion

This study reveals the activities design entrepreneurs engage in to realize their businesses, based on value chain analysis. Currently, the market is ready for design entrepreneurs who work outside the mainstream manufacturing industry. They build their own niche and start businesses. Entrepreneurship is the driving force of economic development; it reorganizes resources to achieve a series of innovation and leads to economic growth. Design entrepreneurs integrate business opportunities into entrepreneurship to contribute to economic vitality and development, bringing new thinking patterns and creating value. The emergence of design entrepreneurs suggests that being an entrepreneur has become a career option for design students. From the viewpoint of design education, entrepreneurship education should be embedded in to the design curriculums to build design students ability to turn product ideas into business realities. In the past, design schools trained students to become professionals who provide design services, rather than becoming entrepreneurs themselves. Current design education should consider providing students entrepreneurial knowledge. By applying value chain analysis, this study explores how design entrepreneurs in Taiwan use their own profession and collaboration or access to resources to create market opportunities and summarizes their entrepreneurial activities. Future research should focus on design entrepreneurs with regard to brand management, marketing, distribution, and other practical experiences to help design practice and teaching curricula.

Design dialogues as a specific mode of communication: about the ongoing exploration of solution space

Terry van Dijk, University of Groningen, Associate Professor, Groningen, Netherlands, t.van.dijk@rug.nl
Matthew Cook, Open University, Milton Keynes, United Kingdom

Abstract. Decision-making with respect to urban design is a particular arena where designerly modes of interaction are used, but placed in the specific context of coordination across a variation of actors. The planning literature that describes how urban design is included in decision-making is poorly connected to design literature. This paper laments this disconnection and shows where design theories reflect planning theories, and where they can further complement in order to create a richer understanding of urban planning.

Keywords: Urban design, designerly approaches, decision-making

Planning involves making decisions about whether and how to change the spaces we live our daily lives in. We may need better road connections, enhanced farming structures, renewed city centers, more homes, higher levees to protect us from flooding, and so on. In the process of deciding, a range of planning options to satisfy society's needs is generated, considered, trimmed down and ultimately decided upon. Given the variety of interests and the power issues involved, this can be a messy, cyclic and time consuming process.

This paper addresses the generation of a range of planning options – the divergence phase. All possible solutions together form what we would like to call the 'Solution space' (cf. Forester, 1989, p.123 and Stempfle & Badke-Schaub, 2002), which is never evident or fully transparent. There are always more possible planning solutions that can be generated than meet the eye. Yet decision-makers in the political arena tend to be quick in choosing a solution and persistent in holding on to it, even when good alternatives come to light. This results in the often encountered polarisation, instead of constructive creativity. Then power, egos and the urge for consensus replace the constructive dialogue that could have been. (cf. Flyvbjerg, 1998)

The idea of keeping things open for exploration rather than opting for a solution and holding onto it, is central to design (Lawson, 2006). We advocate the creation of design dialogues as a way to promote openness, when planning and designing in groups. What insights does Design Studies have to offer? Design Studies inquires into the micro level processes which proceed in actual face to face meetings where various actors meet, discuss, inspect, reject or accept ideas, but also generate, negotiate and create new solutions. Seen in this way, mobilising concerted action implies going through these design cycles together.

Enclosed between a quiet suburb at the fringe of a provincial town and a regional highway lie only a few hectares of scenic meadows. The municipality has grown to consider this the best location for building the town’s new middle school. The residents protest the loss of their scenic view. They want the site to stay like it was. Years of opposition follow, in which positions harden and formal procedures have become the main mode of communication.
The stake is: whether the school will be built or not. There is a lack of trust in the municipality, scarcely sufficient time for the new school’s realisation and the costs of the procedures are high.

Then a designer is invited to mediate. The designer talks to the residents and asks them for their key concerns. Their key concern is the loss of green space, the expectation of high buildings blocking their views and nuisance of students wandering their streets and vandalism or littering their front gardens.

The designer takes his sketch pad and markers. He starts drawing. What if the school buildings will be placed on the farthest side of the site, against the highway, and the sports fields will be at the residents’ side of the site? And what if the suburb and the sports fields were to be divided by a canal lined by native reed land, shrubs and trees, that will serve as a natural moat preventing students to enter the residential streets? With a walking trail along its banks?

The residents gradually agree that be the school site designed in that way, they find it a positive development. The municipality did not have any objection as the design did not impede their objective in any way. So the plan was made. The question was reframed from ‘school or not?’ to ‘what form, if any, will be acceptable?’ This is a true story. It illustrates a pattern that can solve dis-census in any village, town or city. In any country.

This story illustrates the basic premise of our argument: action and reaction in planning stem from imaginary futures of places – the latter are socially constructed in formal and informal interactions between interdependent people. These futures are in principle permanently open for reconsideration or reinterpretation. When the drawing table is allowed to replace the meeting table, another type of dialogue emerges.

The remainder of the paper is structured as follows. In the next Section we provide a brief example of what we mean with design as a mode of communication. After that we show how planning theory, although becoming increasingly oriented toward communication, failed to incorporate notions of design. Therefore, in the fourth Section we turn to an aspect of Design Studies literature that focuses on design meetings. We discern the main strands of this literature that hold valuable lessons for understanding the role of meetings in planning processes. Lessons from Design Studies are further specified and critically discussed in the concluding Section.

**Literature review**

In the mid 20th century, technocratic professionals played a central role in planning processes. Drawing on the principles of scientific inquiry, they sought to understand the development of pre-defined territorial units such as towns, cities and regions and formulated policy prescriptions to manage these processes. However, limits such as bounded rationality (Simon, 1991), to the ‘rational mode of thought’ which underpinned and indeed legitimated such work eroded confidence in it. In response, a number of leading authors adopted a social constructivist perspective on planning processes. This approach is founded on the notion that facts and logic are not independent of people, but are constructed within planning processes.

The 1980s witnessed an upsurge in the interest how planners went about in their everyday
work. A range of insightful books had made the planner and his work the object of study. They became ethnographies that objectively described, but also aimed to normatively prescribe, the professional behaviour of planners. The seminal work of Schön (1983), *The Reflective Practitioner*, stressed the need for planners to be receptive to the people and matter they work with, and constantly learn, adapt and improvise. Forester’s *Planning in the Face of Conflict* (1987) and *Planning in the Face of Power* (1989) reflected on the various skills and strategies planners apparently needed to bring to the table, in order to deal with the many facets of typical planning settings. Based on extensive observations of planners in practice, and interviews, Forester discussed the roles that planners may have to play: mediator, facilitator and deliberator. What role should a planner take, when, and with what ethical attitude?

The bundle of essays on planning practice, published as *The Deliberative Practitioner* (Forester, 1999), again drawing on many examples from everyday planning practice, was a capstone on two decades of finding out in detail what planners do, or ought to do. The book addressed the many roles, forms of knowledge and ethical issues planners need to combine. The essence of planning is deliberation, says Forester, which goes beyond reflection: it is an interactive reflective group process, that includes planners and all the parties they work with, resulting in transformative learning.

Innes expanded on this idea, looking at the wider process surrounding planners, as she was captivated by a fascination with decision making ruled by political process rather than content. She analysed dozens of cases in order to identify whether programs work and why they work (Innes and Booher, 2010). Important insights on how planners can be effective are presented throughout Innes’s publications. These suggest that planning decisions should primarily be rooted in shared meanings, shared knowledge and shared understanding of problem and benefits (Innes, 1996; Booher and Innes, 1999b; Booher and Innes, 2002; Booher and Innes, 2004; Innes, 2004), culminating from a joint process of truly engaged participants.

This literature centres around the local planner that deals with conflicting interests on the building block scale. It addresses mutually dependent people that need interaction (shaped by roles, power) and communication (requiring communicative skills, expertise, knowledge) in order to enable concerted action. The relevance, and indeed necessity, of communication and collaboration in spatial governance subsequently formed the focus of much planning research (cf. Healey, 1992; Innes, 1996; Innes, 1998; Healey, 1997). Planning research (cf. Healey, 2007; Hoch, 2009; van Dijk, 2012) also implies that planning activity involving face to face encounters in particular, includes elements that are analogous with design processes.

We argue that, apart from studying the agency of the planner in a reactive setting (‘conflict arises, how to behave?’), we also need to understand what creative conversations are about. In the sense of: how do groups of interdependent people
constructively explore solution spaces in a designerly way? And how best to do that.

One might wonder, hasn’t there been enough talk about design in planning? The utility of urban design perspectives in spatial planning has been recently highlighted by a number of authors. The discussion between Gunder (2011) Banerjee (2011), Anselin, Nasar and Talen (2011) and Steiner (2011) in their commentary papers in Journal of Planning Education and Research discuss how the practice of specifically ‘urban design', being concentrated on the form and aesthetics of public spaces, relates and should best relate to urban planning, given challenges of globalisation and centralisation. A similar discussion on what role urban design should best take, and who it should serve, developed in Journal of Urban Design (Madanipour, 2011; Childs, 2010; Schmidt and Németh, 2010 and Graffikin et al, 2010) the year before. These discussions juxtapose planning and design as disciplines. As such they do not help understand the (need for) infusion of designerly modes of communication in planning practice. Ironically, by discussing linkages, they nonetheless separate what could be integral to such work.

The next Section explores Design Studies literature to develop a view of design as a mode of planning practice, to help concretise design as a perspective on planning (cf. van Assche et al., 2012). Design studies is concerned with the generic properties of design processes rather than the specifics of various design specialisms, e.g. urban design, engineering design, graphic design. It comprises multiple research themes such as collaborative design and co-creation, visual representations, evolutionary perspectives, complexity and design. Similar to planning theory, many of these aspects of design studies research are founded on approaches from the social sciences, psychology, complexity sciences, science and technology studies, development studies to name but a few. There are handbooks (Susskind, McKearnan, & Thomas-Larmer, 1999; Carpenter & Kennedy, 1991; Sarkissian, 2009; Moffitt & Bordone, 2005; Gastil & Levine, 2005) with practical guidelines to approach planning as a design process, yet Design Studies approach design processes as a scientific object of inquiry.

Design Studies: analysing design meetings

Planning is undertaken by multiple actors working in various construction sites situated in a governance landscape (Healey, 2007). While a single planning pathway to optimal planning solution is unlikely to be followed in these, it is highly likely that there will be re-occurring universal elements (cf. Healey, 2010; 2012). Indeed, no matter how messy and cyclical, ultimately planning at the micro scale involves articulating problems and generating solutions to help resolve these. Of course, there are oscillations between phases and moments when we are thrown back into the process. But too often, this moment is kept implicit and the design leap is done by each actor in isolation.

In this paper we therefore, plea for awareness that we need to unpack and make this moment explicit in what has been called 'Design Thinking' (De Lille et al, 2013) a 'designerly approach' (Luck, 2012) or a 'planning-as-design' perspective (van Assche, et al, 2012). Some call it 'mundane designing' to distinguish it from the highbrow design (Luck, 2012; McDonnell, 2009). It is a cluster of paradigms (Stumpf and McDonnell, 2002; Dorst, 1997), that have in common that they are ways of treating each problem-solving process as a mindset, a process of inventing alternatives (Boland and Collopy, 2004), empathise with
multiple kinds of people using and owning the site (Batterbee and Koskine, 2005), visually
imagining problems and preliminary solutions (Evans, 2011) where words alone would not
convince (Utterback et al., 2006). Designers employ their skills in a continuous creative
dialogue (Gloppen, 2009). Seen in this way, Design Thinking helps prevent communication
in planning being reduced to abstract policy talk; communication that may have a
polarizing effect as conflicting discourses become self-referential and stakeholders no can
longer make sense of what others are trying to say, or why.

Designing is a different mode of communicating, that begs for a specific perspective on
'communication' in planning.

Similar to planning, design activity includes a shifting set of participants and typically
proceeds through various simultaneous interactions distributed in time and space
(McDonnell and Lloyd, 2009). How design proceeds in meetings and the choices made in
these are deemed significant as part of the overall design process ibid. Thus while far from
comprehensive and definitive, design meetings provide an interesting opportunity for
researchers to observe (perhaps glimpse) important aspects of the design process. Major
landmark designs or particular problems which need to be resolved are not the focus of this
research (Luck, 2009). Rather, work on design meetings focuses on how everyday or
mundane/ routine design activity proceeds involving multiple participants including perhaps
most notably, professional designers (e.g. architects), clients and users.

Design meetings research has been consolidated and extended by a landmark UK Research
Council funded project entitled Analysing Design Meetings. This work focused on
naturally occurring design in authentic settings – design meetings. Data were collected
from two design meetings 1) concerned with the design of a specialist pen and 2) the
design of a crematorium. Data were collected using multiple methods such as video and
audio recordings, transcripts, researcher notes and observations.
One data set was created. A team of researchers (from multiple universities) were invited
to analyse the data set using multiple methods. Analyses were rooted in the two main
threads of design studies research 1) design thinking - how designers think in design
meetings and 2) design practice – what designers do in design meetings.
Below we explore each of these strands of research, the methods and approaches used and
insights gained.

Cognitive processes in designing

Much of design studies emphasises cognition and draws on approaches, methods and
insights from the behavioural sciences such as psychology, e.g. protocol analysis.
Design thinking provides a useful way of identifying and resolving problems in a variety of
settings, not only those concerned with what we might traditionally associate with design,
but also other field such as business (cf. Kahneman, 2003), management (cf. Huisman,

Design cognition involves considering the design object, seeing and gradually and
cyclically constructing images of properties, structures and potentialities of these. This is
often conceptualised as a dialogue between observers and material objects and has been
studied by among many authors, see for instance: Schon and Wiggins, 1992; Dorst and
Cross, 2001; Détienne, 2004; Luck, 2012. Importantly, design thinking is not the exclusive preserve of professional designers, rather something which may be distributed among all participants in design meetings. Below we explore aspects of design thinking observed in design meetings.

**Framing and reframing.** The ability to reframe a problematic situation in new and interesting ways is widely seen as one of the key characteristics of design thinking (cf. Lawson, 2006). Drawing on the work of Schon (1991), research shows that (re)framing is a necessary creative step which allows a design solution to be produced. Reframing is important in the early stages of design projects – in briefings (Paten and Dorst, 2011). Briefings are interactions through which a mutual understanding (often between the client and designer) of what the design project will be about is developed *ibid.* Here, the client may set out a problem which needs to be resolved, which may be in written or verbal form and detailed or fuzzy. Designers then negotiate with the client to define a vision of what the project. Reflection in action is central to such negotiations. Designers attempt reframing to negotiate a mutually apprehended frame that is actionable (Lawson, 2006). Here designers have been found to deploy strategies to: shift the client from viewing the situation as a problem solving exercise; deconstruct presuppositions and loosen client fixation on particular outcomes; create dialogical ways of interacting with stakeholders and the situation to allow for exploration of the context (Paten and Dorst, 2011). In such processes, designers reflect in action with their clients; abstract from a client’s currently held frame to de-structure a situation so that new frames can be communicated and adopted. Strategies for abstraction and consequent reframing include (Paten and Dorst, 2011):

1) use of metaphor and analogy

2) contextual engagement through research

3) conjecture – reframing assisted by exploring the abstracted conjectured view of the situation.

During the briefing process, designers strategically and actively modify and gain acceptance for more desirable and workable frames with their clients. Similar to planning (cf. Healey, 2007), design frames are not necessarily new but rather often based on valued frames cultivated over projects within the designer’s practice as a professional meta activity.

**Co-evolutionary Model.** Reframing during briefing is best achieved with earlier entry into the project with the client and when there’s a co-evolution of problem and solution spaces (comparable to Forester’s (1989) Chapter 8) as part of a highly iterative exploration of the design situation with the client. Indeed, underpinning much of the research on design thinking is a co-evolutionary model of design (Dorst and Cross, 2001). This contribution to knowledge is perhaps among the most significant to arise from design studies (Wiltsching et al., 2013).

Traditional models of design suggest that design problems are fixed and therefore that the search for potential solutions proceeds in a unitary problem space that is defined by a relatively stable set of design requirements and constraints. In contrast, Dorst and Cross (2001) showed that creative design concepts are developed through an iterative process, in which design problems and potential solutions co-evolve. Thus design involves exploring two conceptual spaces, a problem space and a solution space, with developments in each space informing the other.
Designers reframe in the early stages of design - briefing meetings (Paton and Dorst, 2011). They abstract from the brief – get to the problem behind the problem. Here their aim is to negotiate with the client a frame that is actionable. Thus designers actively promote fluidity and experimentation: a cycle, that Schon and Wiggins (1992) describe as: see (inquisitively), change (in a virtual sense), see again (in the sense of: judgement), and repeat the last two steps. In that process, designers deliberately question frames of reference, to bring novel design possibilities to light that instantiate problems in need of a solution and enable designers and design researchers to question taken for granted assumptions (Luck, 2009). It may mean going back in the cycle, instead of directly generating alternatives. Together, these forms of 'unfreezing' and experimenting can unleash a creativity that formal arenas of policy-making systematically fail to achieve.

The co-evolution of problems and solutions has been observed in design meetings involving multiple actors (Wiltsching et al., 2013). Design solutions are posited by participants in response to requirements that define the design problem. Following evaluation in light of requirements, design solutions are modified. But interestingly, so too are the requirements, in light of a novel solution attempt. Thus the overall design space explored in meetings is defined by a creative search for both solutions and problems.

Empirical data collected in design meetings shows how participants move in this design space. In commercial settings team leaders guide this process. As design ideas are generated, they modify requirements and thus the problem space. This then stimulates other team members to generate further design ideas. Thus design does not necessarily involve creative leaps between problem and solution in the mind of leading designers. Rather, multiple participants engaged in the iterative construction of bridges between design problem and solutions. Ibid.

Analogies and object references. As frames flow into spatial strategy making episodes (Healey, 2007), similarly design frames, ideas and concepts flow in from elsewhere to the co-evolutionary design processes (cf. Stacey, Eckert and Earl, 2009). Thus analogical reasoning forms the focus of a number of studies concerned with design meetings. Analogical reasoning involves assessing and transferring previously acquired knowledge of objects, attributes and relations to support design activity (Ball and Christensen, 2009) For example, this may involve drawing on object references - referring to objects that participants have encountered previously, other designs and so on. In general, analogical reasoning seems to be particularly prevalent when there is epistemic uncertainty. More specifically, it occurs in design meetings for diverse purposes including (Ball and Christensen, 2009):

- Problem identification – noticing a possible problem in the emerging design, where the problem was taken from an analogous source domain
- Solution generation - transferring possible solution concepts from the source domain to the target domain
- Explanation - using a concept from the source domain to explain some aspect of the target domain to members of the design team

While object references and other analogies have been re-drawn from the specific domain in which the design process analysed proceeds (e.g. industrial design,
engineering design), research shows that these can also be drawn from diverse settings (Stacey, Eckert and Earl, 2009). Consequently, design studies provides concrete insights on the work of design frames, concepts and ideas in meetings.

**Designing as a social process**

While cognitive processes are important, there is growing concern that these are overemphasised in design studies. In response a reparative, complementary stream of research has been developed which focuses on how people *practice* design. Drawing on ethnomethodology (EM) and conversation analysis (CA), studies have focused on naturally occurring talk through which designs are developed and enacted (McDonnel and Lloyd, 2009). Specific aspects of design meetings explored include how roles such as client, architect and user are constructed (Oak, 2009), how collaborative negotiations proceed (McDonnell, 2009), how design concepts mediate moves made by participants within design spaces (Luck, 2009). We consider each of these themes below.

*Constructing roles in the design process.* Within design meetings roles performed often accord with everyday perceptions of design practice but also that roles are far from unproblematic as design meetings participants orient to and perform roles (such as client, user, designer) through their talk (Oak, 2009). Participants talk in certain ways which reflect, justify and allow them to perform their respective roles. Through such interactions speakers organise their social roles and ultimately get things done.

Although design is often collaborative in one way or another, ownership of the design process and outcomes are often negotiated in light of the roles participants perform.

For example, Oak (2009; 2012) shows how in architectural design meetings, architects can claim ownership of these and ultimately processes, by deciding the structure and topics to be discussed. Equally, Oak (2009) shows how clients can give deliberately ambiguous answers to architect’s requests for information as a deferral strategy: the client defers to the architects knowledge and expertise and allows the architect to perform the role of expert designer and the client to adopt the position of layperson. Evidence suggests that while professional designers may reflect on what constitutes design knowledge and appropriate behaviours in design meetings, other non experts such as clients are unlikely to do so. *ibid*

*Collaborative negotiation.* Research has also explored how designs are negotiated in design meetings which do not claim to be overtly participatory or collaborative (cf. McDonnell, 2009). Here, research focuses on how various actors communicate sufficiently to move the design forward to the mutual satisfaction of participants. Such negotiation does not necessarily imply opposing positions or conflicts, rather working together toward shared objectives is emphasised. For example, McDonnel (2009) shows how within design meetings, information is sought and given by professional designers (e.g. architects), client and users (e.g. building users). Through tentative excursions one participant can invoke the position or knowledge of the other to propose or justify a design decision, which provokes in turn an expert response. Indeed, in design meetings, the expertise of participants and its assertion provides a practical way of getting design done. In some instances, the expertise of the professional designer plays a central role in the process: structuring meeting agendas and deciding what topics should be discussed. Similarly the expertise of building users are also important, e.g. to provide
information on how a building might be used post construction.

Nonetheless, the relationship between expertise and roles played in design meetings is complex Oak (2009). Roles are continually negotiated and emerge from social interaction. For example, professional designers are also users of products, services, buildings and so on. These experiences can provide the professional with a starting point for drawing out information from building users. Equally, expert building users are also capable of aesthetic, symbolic and other properties of space. Again, providing a basis, if not a starting point for collaborative negotiation with design professionals. Ibid.

Social production of design concepts. Drawing on the co-evolutionary model of design discussed above, research on design meetings has investigated how participants interact to produce and accomplish changes to a design concept as it co-evolves (Luck, 2009). Drawing on Lawson (1994) and Dong (2007), Luck (2009) explores how an underpinning design concept mediates the relationship between design problems and solutions and thus moves made by participants in the design space, i.e. problem and solution spaces. Here the design concept has no material reality but nonetheless is semantically real and exerts considerable agency in design. Such objects act as a point of reference for designers, while other actions that modify the design are somewhat fluid and ongoing.

Design studies makes use of the idea of boundary objects from science and technology studies (STS) to explore the social production and work of the design concept (Luck 2009). Boundary objects mediate communication between people with different knowledge concerns. Over time, through interaction they are modified. Intermediary objects are a subset of boundary objects that are specific to design. They represent the intermediate states of a final deliverable for a project. The design concept is a non material object which is obdurate compared with design ideas that are generated in the design space. The design concept is not a boundary or intermediary object. Rather, such objects (e.g. visual representations) may be generated as part of idea generation, relate to and be evaluated against the design concept. Ibid.

Discussion

Communication is crucial to planning, and we contend that the act of designing is a specific mode of communication. Whereas much planning research has studied the reactive communication of planners with stakeholders at micro-level (see Section 2), it takes a creative dialogue of people with the places at large in order to prepare our cities and regions for future needs.

There is a difference between meeting-table talks and drawing-table talks (see Section 1). We argue that in the latter, a designerly mode of communication, solution spaces are explored more thoroughly, potentially yielding more effective solutions with less resistance.

Design studies (see Section 3) have shed light on designerly dialogues, that we divided into cognitive aspects (constructing images of the situation in a co-evolutionary way) and social aspects (role construction and negotiation). In the discussion we want to address two questions: (a) are the insights from Design Studies new to the planning debate, and (b) what obstacles are there to adopt a designerly approach in real life planning processes?
The answers to question (a) is: yes and no, the mechanisms revealed in Design Studies literature all are also present in planning literature – reflections that differ in important respects from Design Studies. Planning research widely acknowledges the social-constructivist nature of problem-definition that Design Studies similarly reveals. Influential texts from Flyvbjerg (1998), Hoch (2007), Throgmorton (1996) and Healey (2007) alike stress that ‘information’ is indeed constructed in the minds of people. Objective representations of problems and the value of solutions are illusions. Similarly, the notion of frames that represent and reproduce interpretations of reality is also widespread in planning research (Forester, 1993; Innes, 1998; Ernste, 2012; Dembski, 2012). There is an importance difference, however.

Whereas Design Studies see a learning process between designer and object, in which the designer is one half of the dialogue, planning scholars show that constructions mainly emanate between people, and from their intentions, that in turn emanate from the network of relations that people operate in. The comparison with Design Studies shows that in a way the planners’ perspective has grown detached from physical reality and deals more about power and politics. This is an unintended result of the ‘communicative turn’ that has also implied an ‘institutional turn’ where process became central at the expense of content conveyed by these processes. Design Studies show that framing is foremost about a proper understanding of the situation at hand – in the substantive physical sense.

Conceptual thinking is another parallel between planning and designing thinking with an important difference. The use of analogies and metaphors in spatial concepts facilitates the persuasion and exchange of basic design choices. The work of Wil Zonneveld and Stephanie Dühr in particular has demonstrated that planners as well are, although in variable degree geographically speaking, avid producers of concepts (Hajer and Zonneveld, 2000; Zonneveld, 2005; Dühr, Stead and Zonneveld, 2007; Dühr, 2007).

Yet in this case again, the way they are constructed in practices of planning emphasizes the communicative effect of concepts, that may deviate from how well the concept connects to the physical reality and its possibilities. In other words, a concept that people have come to believe, like and support does not necessarily make sense when put into practice. Again, designerly dialogues may bring a dialogue with physical reality back into the discussion.

The second part of this discussion addresses (b) obstacles for applicability of a more designerly dialogue. We claim that planning processes always imply elements of design, and that processes could benefit from a more extended designerly mode. The fact that it is common to see actors ‘jump to solutions’ and hold on to them, suggests that there are costs to designerly dialogues. What characteristics of planning processes complicate the adoption of the designerly approach? We discuss three characteristics:
1) a natural tendency toward broad brush communication, 2) the need for illusion of certainty, and 3) role closure.

Often plans are communicated in a broad brush fashion: ‘a school for 800 students will be built here’, ‘a windfarm will be placed there’, ‘a highway has to cross through this part of the city’. However, recipients of that message will translate a broad brush message into concrete physical form – and respond negatively. The example in Section 1 shows that whether a ‘school for 800 students’ next to your street is a good or a bad thing depends on what it looks like: how it is designed. The brevity of statements may be partly explained by the educational background prevalent among local government staff. Trained to handle
legal and policy-administrative processes, they may be less inclined to appreciate the concrete and creative implications of their messages.

Secondly, and in line with our first observation, planning processes pursue concerted action, and that will only occur when actors feel confident that other actors will move in a certain direction – because of interdependence, the outcomes of the action of actor A depend on the actions of others. Businesses, developers and governments need to cooperate. This requires an illusion of certainty, seducing every actor to go ahead. Hanging on to decisions once taken is a logical reflex. ‘Certainty’ conflicts with the notion of ‘designerly’, in which all options are open for debate. That could explain why actors may avoid constructive dialogue and rather strive for a quick fix and confirm and defend decisions once made. Decision-making procedures aggravate this tendency, funnelling processes and suppressing dialogue.

However, within certain frames defined in a previous decision, there may still be room for designerly dialogues. In the example Section 1 provides, although the site was designated for a school to be built, the site’s design was still open for discussion. Within the main decision, residents and municipality constructively found a mutually satisfying solution. So the question is not: certainty or flexibility, rather: what exactly is fixed because of formal decisions, investments and procedures and what options within those frames are still flexible and open for discussion? Choices are always nested in cascades of choices, typically on various scales, some of which may be givens, some open for dialogue. By keeping the designerly dialogue explicitly open on well defined flexible parts, resistance may decrease and eventual outcomes may improve.

The third explanation for lack of designerly dialogues in practice is a game theoretical one. Every actor in an interactive and interdependent process forms its own role definition. The role implies a certain set of main objectives related to the actor’s identity. Who feels responsibility for creatively exploring solution space in order to find a solution that satisfies all? When role perception tends toward rivalry and competition (‘who gets his way?’) a new player needs to be introduced: an impartial inspirator that connects needs of people and helps find the opportunities of a place.

Conclusion

Summarizing, reaping the benefits of a designerly dialogue means installing the appropriate institutional capacity, by actors hiring designerly expertise, processes in which fixed frames and the choices open for debate within them are teased apart, and introducing designated actors with the explicit role to keep exploring solution space. Senior design professionals are known to effectively lead, facilitate and mediate this co-evolutionary process – they are responsible for leading the creative construction of a bridge between spatial problems and planning solutions. Indeed, neither problems and solutions may be evident (even in the presence of a frame) as they may not be perceived by actors or considered in terms of their ability to assess them (cf. Lemon, 2007). In other words, there may be many more options that still might be generated that meet the eye.

Identifying problems and forging solutions is not a technical activity that produces outcomes that are objectively suitable and better or worse, against some scale, rather a deeply social process. As problems and solutions emerge actors that engage in the process gradually learn and develop their perspectives and preferences. Exploring the array of possible solutions
requires creative collaboration across different people. It needs focus, cooperation and concentration on the spatial problem at hand. In planning facilitation techniques required to help participants build bridges between problem and solution spaces? Facilitators are needed to rearticulate and modify problems and requirements, which then leads other participants to generate further planning solutions in response.

Beyond Greener Things: sustainability within communication design practice.

Niki Wallace University of South Australia, Adelaide, Australia, niki.wallace@mymail.unisa.edu.au
Robert Crocker University of South Australia, Adelaide, Australia, robert.crocker@unisa.edu.au

Abstract

This paper reviews contemporary communication design practice in Australia through a series of interviews with practitioners, conducted to better understand the place of sustainability in contemporary practice. It is especially concerned with the expectations and experience of designers, and their attitudes towards sustainability in practice, and the contrast between designing ‘greener things’ and establishing more sustainable outcomes for their clients through deeper collaboration. The paper is part of a larger PhD project attempting to establish ways of expanding the understanding of sustainability for communication designers.

Keywords: sustainability, communication design, professional practice

Contemporary communication design practice has established a sense of professional identity through an alignment with business, where the primary concern is profitability and growth (Claver-Fine, 2016; Julier & Moor, 2009; Walker, 2014). Many have argued that this status quo has locked business (and by association, communication design) into systems that promote unsustainable behaviours such as accelerated consumption, increased energy use and resource mismanagement (Fry, 2009; Fuad-Luke, 2009; Walker, 2014). In other design disciplines such as industrial design and architecture, the complex or so-called ‘wicked problems’ of sustainability can to some extent be addressed through changes to materials and processes. However, in communication design practice sustainability is positioned within a very different setting, affected by the client’s understanding of sustainability and how this may or may not appear in their desired communication; as well as by the designer’s understanding of what the pursuit of sustainability in the context of the project might involve. This typically ends in reductive responses to sustainability, constrained by the tension between what designers believe is the right approach, the desire to create award-winning (or ‘good’) work, and their perceptions of what the business market will most readily accommodate.

This can result in a passivity towards issues of sustainability, and a form of ‘standard sustainability practice’ that reduces the goal of sustainability to its most accessible material dimensions, typically reducing waste and using ‘greener things’, such as recycled paper, vegetable inks et cetera, (Claver-Fine, 2016; McDonough & Braungart, 2010; Sherin, 2008) and only when the client budget can accommodate it (Benson & Perullo, 2017). However there is a growing body of literature that argues design for sustainability should aim to address sustainability more holistically and permit solutions...
that step outside of the realm of ‘things’ by considering values and the relations between people and the environment more deeply (Acaroglu, 2017; Irwin, Kossoff, & Tonkinwise, 2013; Manzini & Walker, 2008; Walker, 2014). Design for sustainability should thus encourage more open collaborations that reposition communication designers to better influence clients’ business practices and steer project outcomes.

In order to gain greater insights into this problem, and how sustainability is approached in communication design practice, an analytical autoethnographic study was undertaken by author one (Wallace) with the guidance and support of author two (Crocker). Anderson describes analytical autoethnography as a study where the “researcher is a full member of the research group” and “is committed to developing theoretical understandings” (Anderson, 2006 p373). This approach differs from traditional autoethnography and evocative autoethnography in its explicit analysis and contextualisation within a theoretical framework (C. Ellis, Adams, & Bochner, 2011; C. S. Ellis & Bochner, 2006; Pace, 2012). Reflections on contemporary practice were informed by the literature, Wallace’s own experiences as a practitioner, and data collected from semi-structured interviews. Thirteen Australian communication design practitioners were interviewed to establish their considerations of the norms of practice and the role sustainability plays in their own work. They performed in varying roles and responsibilities including owners, directors, employees in studios and in-house roles, sole practitioners and freelancers. Most interviewees specialised in either digital or print mediums; however, there were also three hybrid practitioners – those who worked across multiple media – and two consultants amongst those interviewed. Interview data was collated into a series of visual notations, used as a means of reflecting on the interviews, recognising patterns in the collected data, identifying themes and making connections to the existing literature. This process draws on coding methods from Glaser and Strauss’s grounded theory (Barney G. Glaser, 2013, 2014; B. Glaser & Strauss, 1967; Holton, 2007), but is primarily informed by reflective practice (Schön, 1983; Yanow, 2009; Yanow & Tsoukas, 2009; Yee, 2010) fully utilising techniques of reflection in-action (interview notes) and on-action (visual notations, conversational reflections). The idea that practitioners know more than they can articulate (Schön, 1983) has underpinned the reflective notation process, and the reflective conversations between the authors of this paper also guided the data analysis.

Reflecting on the collected data reveals perceptions and understandings of sustainability varied from one practitioner to the next, however there was an important common thread: the believe that sustainability amounted to the creation of ‘greener things’ through technical considerations such as recycled paper or vegetable ink. Fear that pursuing greater sustainability might negatively impact the creative process, along with the perceived economic constraints of their work appear to have led to passivity towards sustainability in most practices. For many it was not front of mind, others were introducing some ‘green things’ some of the time, but not much more. This paper contrasts this rather limited, materialistic approach to sustainability with deeper collaborative approaches that investigate alternative, more sustainable outcomes for
Sustainability in this second sense can be understood not just in terms of the physicality of practice, but also in terms of communication itself, with the designer working collaboratively to shift the beliefs and attitudes of their clients and alter the outcomes affected by the work of design.

A division appeared to occur between those interviewees focussed on 2D/print design and those working in a digital space. Digital designers made clear that it was more common to work collaboratively, and their approaches to communication revealed greater interactivity in both process and outcomes. This is also reflected in the literature which outlines high functioning relationships as crucial to successful collaboration (Bjögvinsson, Ehn, & Hillgren, 2012; Ehn, 2011; Steen, 2011, 2013) Whilst ‘things’ remained the focus of many, those working strategically felt they were better positioned to influence clients and believed they were treated as experts rather than resources. The connection between the use of strategy and this increased influence of the designer is also echoed in the literature (Harland, 2011; Muratovski, 2016; Tischner, 2006). This emerging model for sustainable practice appears to be underpinned by strategic thinking and crosses over the practice of digital and print design, permitting increased collaboration, greater influence and more holistic, two-way approaches to communication design.

**Making money, making things: tensions between business and design**

The tension deriving from business demands within design practice pressures many designers to create work with limitations that can impact their practice economically, creatively and ethically, with direct implications for their willingness to consider sustainability in more depth. This is evident in the literature (Benson & Perullo, 2017; Bierut, Drenttel, & Heller, 2012; Julier & Moor, 2009) and its implications have also been captured in the data collected as part of this research. Since the 1990s global recessions have seen the cost of design questioned by many clients. In contemporary practice, it is also recognised that during periods of slow economic growth clients’ become hesitant to invest in design, often seeking the cheapest solutions possible. Unfavourable economic climates for the designer can lead to ‘chasing the dollar’, the result of which can compromise ethical decision-making and creativity in order to pay the bills. From the interviews, it was ascertained that when client budgets are tight the design process can be modified to accommodate – perhaps thinking time is reduced, or fewer concepts are presented, short-cuts are taken, or reference materials are drawn upon to inform the concept rather than developing a new creative approach.

These compromises made to accommodate financial constraints were also identified by Dorland in Canadian practice (Dorland, 2009) and by Springer in the UK (Springer, 2009), and could be perceived as devaluing design itself, leaving practitioners with the problem of how to re-value their work, potentially through non-commercial means. These constraints can also impact the designer’s ability to design for sustainability; shortcuts taken in a ‘standardised’ design process can also imply a reduction of
available time to address sustainability through adequate problem definition, research and exploration of more sustainable solutions.

For the client, time pressures are usually about getting to market the fastest or by the cheapest means possible. For designers, a fast-tracked design process such as Google Venture’s 5-day sprint (Google, 2016) would appear to permit some exploration, some design thinking, and some rapid prototyping for consideration, within a tight timeframe and budget. This outcome satisfies clients’ desires to maximise profit, while permitting designers to create and demonstrate the value of these processes to the client. However, it could also be argued that this fast-tracked creative process also results in changed expectations. Once a client has had a taste of ‘process for peanuts’, it may become harder to engage them in a deeper creative process next time. Will such a ‘teaser’ sell a deeper exploration and the accompanying bigger budget for future projects, or will it result in a desire for more, and similarly cheap, fast teasers?

The relationship between clients and designers is usually structured around business needs, the client’s needs as well as the designer’s. The client engages the designer to help achieve their desired business outcomes, and the designer strives to keep the client happy in order to pay their bills. This financial co-dependence does more than impact the speed with which designers can produce work, it also has a potential to impact other areas of practice such as creativity, sustainability and even ethics. Sol Sender’s essay about Herbert Bayer’s work on the 1936 Nazi propaganda piece, “Deutschland Ausstellung”, shows a fascinating power play between the client and designer, whose wife and daughter were both Jewish (Sender, 2002). Sender’s reflections on this work also capture an interesting line of questioning: how much do we know about our clients and how much should we know? How much did Bayer know? How much should he have known? Did Bayer’s desire to ‘pay the bills’ justify a complicit client-designer relationship with the Nazi party? Whilst this example is extreme, it demonstrates the potential harm caused by the tension between personal ethics and the designer’s immediate financial needs.

Benson and Napier explored how design decision-making can be guided by designers’ values (Benson & Napier, 2012). Their research along with that of the Public Interest Research Centre (PIRC) (Holmes, Blackmore, Hawkins, & Wakeford, 2011) reveals that if more intrinsic (and typically more ethical) values underpin the designer’s approach and thinking, then project framing can become more sustainable, and a greater consideration can be given to ethical issues, such as those relating to social justice and the environment. This same literature can be used to argue that extrinsic values such as financial security and reputation can drive business concerns and impact on client-designer relationships and the ensuing design process. As Jelly Helm (Helm, 2002) asked when considering the concept of ethical neutrality in client relationships, “if our clients are leading us down a path that is not socially or ecologically sustainable, or that is harmful to human nature, do we resist, and how?” Helm’s essay does not answer this question, poignant as it may be, but it does highlight how an ethical framework or lack thereof can create a point of tension in practice, where demands on the designer can push them into greater passivity and conformity with client wishes.
Some clients may request consideration of sustainability, which can prompt designers to design accordingly, however the norms of the designers interviewed, echo a significant supporting literature, indicating that sustainability is not at present a standard consideration for communication designers or their clients in most contexts. Sustainability in practice is usually misinterpreted as a technical consideration e.g. recycled paper or vegetable ink. This limited understanding of sustainability can be readily translated into standard practice, yet many designers remain passive and do not bother with these very limited emblems of sustainability in their practice.

In addition, it is apparent in the historical evolution of communication design, and the recent technical shift to digital processes (Meggs & Purvis, 2016), that an older distinction between the practice of graphic design and the practice of communication design could also influence how sustainability is understood and applied in practice. The longevity and significance of this distinction is perhaps most apparent in the tendency for practitioners to identify as one or the other, as a communication designer or graphic designer. During interviews, practitioners who identified as communication designers also implied they had a deeper and more strategic approach to design, and this was often underscored by a tendency to work with broader business strategies that crossed over between digital and print approaches. Whereas those who identified as graphic designers appeared to adopt an aesthetic approach to communication design specific to their area of specialisation, and to focus more on designed outcomes in to a given brief.

When considered in terms of sustainability, an aesthetic focus could limit a designer’s attention to the object of the process, and result in making ‘greener things’. Whilst in principle this appears a valid undertaking, in practice, project stakeholders such as clients and suppliers can hinder this approach. In the introduction to Design to renourish, the co-author/designers describe their challenges in creating a book about sustainable graphic design that could act as a case study, an outcome that despite their best efforts, was derailed by their publisher due to financial concerns (Benson & Perullo, 2017). A communication designer could have more potential to respond to matters of sustainability through strategic approaches that extend beyond this limited focus on ‘greener things’. It seems that once designers’ thinking expands beyond an aesthetic finish, space can be created for sustainable outcomes that are less object oriented, or ‘thing’ focussed. In this space there is room to consider people and the environment, and greater potential for collaboration that can lead to a more influential relationship with clients. From this influence comes the capacity to steer projects towards outcomes that are more sustainable.

The reductive approach of designing ‘greener things,’ seems driven by routinisation and the unquestioned tradition of designing as a form of making, but this approach is quite distinct from design for sustainability. ‘Greener things’ might create surface level technical improvements through material selection and use, but as Benson and Perullo demonstrate, this can be limited and impacted by external forces such as clients and suppliers. Furthermore, it does not adequately address the ‘wicked problems’ of
sustainability, particularly in relation to consumption. Design for sustainability, by contrast, can affect deeper change through what Ezio Manzini calls *enabling solutions* that “enable people to live as they like, and in a sustainable way” (Manzini, 2006 p11). Manzini and Walker describe design for sustainability as strategic; it involves deeper thinking, collaboration and facilitation (Manzini & Walker, 2008). With the creation of ‘greener things’ designers can still contribute to the status quo, whereas design for sustainability is fundamentally aimed at creating change.

**Strategy, technology and interaction: more communication, less ‘thing’**

A splintering in what could be considered ‘standard practice’ emerged from the interviews in relation to strategy; designers following a more strategic approach appear to have differentiated themselves in ways that could add value for their clients. Strategic designers indicated they were engaged at much earlier stages of a project, and felt they could influence their clients more significantly, especially in terms of more sustainable outcomes. Some still remained focussed on the ‘thing’ to be designed, and described their use of strategy as a means to better position or target a designed outcome. Others were less focussed on the immediate outcome of the design itself and instead aimed to create integrated and connected experiences. These experiences sometimes utilised designed ‘things’, however these designers’ more holistic and strategic approaches also resulted in them occupying more influential positions with their clients; they were viewed as experts, respected as such, and not relegated to a resource, to add finishing touches to a predetermined outcome.

The overarching trend amongst those interviewed suggested that most maintain a focus on ‘things’ as an end-outcome. Most print designers spoke of their focus on making tangible, 2D ‘things’, and many digital designers had a focus on making digital ‘things’ such as websites or animations. Reflection on the interviews brought more clarity to the problems inherent in this focus on outcomes, on ‘things’, and the closed end-point that comes from deliverables that are mainly product or ‘thing’ focussed. Once such an outcome, a ‘thing’, is delivered, the client-designer relationship also ends; the relationship becomes symmetrical, and is defined by the transaction between the two parties for the (final) delivery of a specified product (Sennett, 2003). However, designers working more strategically appear to be carving a richer, more active space for themselves, facilitating meaningful long-lasting, more asymmetrical, mutually beneficial relationships with their clients.

Despite this overemphasis by many interviewees on products and outcomes, analysing their approaches to design revealed that the digital design process allows for a greater awareness and willingness to engage with sustainability within the broader context of the client’s work and audience. This is apparent in a number of areas including human-centred approaches used in user experience design, and more engagement in collaborative processes in the creation of digital/experiential/service-based ‘things’ (Björgvinsson et al., 2012; Ehn, 2011; Steen, 2013).

Collaboration is an important agent of change in contemporary practice, and has become
an increasingly valued part of the digital design process, usually described in terms of ‘co-creation’ or ‘co-design’ (Sanders & Stappers, 2008; Steen, 2013). There is a large body of literature describing co-creation in its many forms, highlighting that each method is unique, whilst also overlapping in process, desired outcomes and the inherent challenges within them (Björgvinsson et al., 2012; Ehn, 2011; Karasti, 2014; Mulder & Stappers, 2009; Sanders & Stappers, 2008; Steen, 2013). Marc Steen highlights that virtues such as curiosity, cooperation and creativity underpinning this process is key to successful collaboration (Steen, 2011) reinforcing Sennett’s **asymmetrical relationships** as a key component in designing for sustainability (Sennett, 2003).

From the literature, interviews and observations from practice, it is evident that each collaborator can bring a unique skillset and body of knowledge, an aspect that creates more effective teams. At its core, collaboration builds relationships that acknowledge differing expertise and allows for a richer understanding of the end-user’s experience. Co-creative collaboration seats the designer and the client at the same table (along with other experts and stakeholders such as end-users), and has already successfully influenced sustainability within other sub-disciplines such as fashion and industrial design (Chapman, 2009; Niinimäki & Hassi, 2011; Vuletich, 2013). From a re-positioning also comes the potential for designers to step away from their role as a job-specific resource, and plant themselves firmly in the expert’s seat. The resultant synergy between those who are considered experts can facilitate the creation of services and experiences that are less reliant on the material outcomes or ‘things’.

Paradoxically, engaging more directly with the life and work of the clients and their audience or ‘end users’ can also lead to a longer-term ‘asymmetrical’ relationship and better financial returns. Digital designers described the benefits of a greater acceptance of pre-project scoping fees, providing a budget for better identification of the true needs and problems to be solved, and more opportunity for influence over project direction and end-outcomes. Despite these beneficial advantages, very few digital designers being interviewed acknowledged this as something distinct or different to other sub-disciplines of design, and even fewer harnessed this power towards more sustainable outcomes. It would seem that regardless of a practice’s specialisation in print or digital, sustainability is rarely considered as a native part of the design process but rather as a series of pragmatic fixes to be applied within each practice. Despite this, there are methods used in the digital design process that are more akin to design for sustainability (even if unintentionally so) and as explorations of these methods deepen, they reveal potential benefits for print designers too.

Digital design has gained another distinct advantage through its responsiveness to its surroundings, and ability to facilitate greater interaction between people and ‘things’. During interviews, print designers expressed an affinity towards the tactility of 2D ‘things’, however the lack of two-way interaction between a printed ‘thing’ and its audience brought to the fore an interesting question: are print designers transmitting one-way messages through the ‘things’ they design, whereas do the digital ‘things’ created by digital designers create opportunities for a more interactive process of exchange? In some sense, the collaborative and interactive nature of digital design appears to fulfil the
role of communication design more deeply through its ability to engage in two-way communication and through its enabling of longer lasting asymmetrical relationships.

**Positioning Design: Getting more than an empty seat at the table**

Designers acting as traditional intermediaries between a client and their audience have less impact on their client’s decision-making (M. Glaser, 2001, 2004; Soar, 2002) and their position as resource rather than expert reduces their potential to influence clients and project outcomes. This leads to greater passivity and conformity to clients’ desires and often results in unchangeable briefs for unsustainable end-outcomes. Glaser, Heller, Wild and others have all identified designers’ positioning as an area of weakness, and open to improvement (Bierut et al., 2012). During an interview, one designer declared, “I might be at the table but it is still not on the table”; revealing one of the many challenges designers face in repositioning themselves.

Getting the seat is hard enough, doing something meaningful with it is a challenge in itself.

‘Standard practice’ within communication design appears to be heavily influenced by the requirement of meeting clients’ needs, and many designers agree that clients can impact their practice in a variety of ways (Julier & Moor, 2009). But these needs, as defined by the client, are often at odds with what the designer might discover if they could engage more directly with the problem to be solved. Leyla Acarglu’s *Disruptive Design Methodology* outlines problem mining as key to designing for sustainability (Acaroglu, 2017), however this mining process can be ineffective if constrained by preconceived notions of needs. Issues arising from this too ready acceptance of the constraints created by the client can have significant financial, creative and methodological impacts. Most of these stem from attempting to meet the clients’ needs within restricted budgets and timeframes, and specifically without the time to investigate the larger context of the problem or to engage directly with the relevant stakeholders through collaborative processes.

AnneMarie Dorland discusses the limitations that financial and time restraints placed on creativity in Canadian practice (Dorland, 2009) and Paul Springer notes the new trend for transparency and post-project auditing in practices in the UK in response to these budgetary pressures (Springer, 2009). In Dorland’s exploration of routines in design studios she highlights the reality of contemporary practice as being less a space of play and more a space of routine and structure. This space presents systems described by Negus in Dorland as “well-established production and occupational formulae”, (Dorland, 2009 p116) performed to meet client needs within restricted budgets. In Australian practice, many of these same problems were identified through interviews with practitioners. Sentiments of *doing whatever it takes to get the job done* were common, and the shortcuts described repeat those found by Dorland in Canadian practice, where routine and structure replace fluid creative processes.

The positive impacts of creativity on business are now widely documented, and the benefits that businesses can gain from design thinking are being widely discussed and recognised (Kimbell, 2011; Leavy, 2012). However the same cannot necessarily be said
about the impact of business on the designer’s creativity, where financial concerns and imposed time constraints can place undue pressure on the designer’s most essential creative work. Project budgets set by clients are an accepted part of professional practice. Sometimes budgets are generous, but more frequently they limit the possibilities for creative exploration as part of design thinking, design making (production) and design implementation (printing/launch). This hampers and reduces a designer’s potential to explore alternative approaches for design and production, an issue that can also result in less sustainable end-outcomes that focus on aesthetics rather than ethics. Again we are faced with this idea of using “occupational formulae” (Dorland, 2009 p 116) in order to meet deadlines and budgets, and because the principles of sustainability are not part of this typical formulae, project constraints leave little space for their consideration. Designers have much to contribute towards solving the ‘wicked problem’ of sustainability, but will require appropriate time for problem definition, design thinking and creative work as well as an expanded understanding of what design for sustainability means.

The formulaic responses present in contemporary practice not only limit the potential to address sustainability through the work, but also undermine the value of design as a creative whole. The goal of creating ‘great work’ and winning awards appeared to be common amongst the designers interviewed, who valued creativity and felt it was a key contributor to design culture, thereby increasing the value of design. Whether the desired personal goal of those interviewed seemed to be the art of design or just wanting to leave their mark, most agreed on the importance of high quality creative work. Some practitioners implied that for some projects they would go over budget and wear any associated financial loss, suggesting that regardless of the financial implications, designers value the creative currency of practice. However, it was evident in these interviews, as well as in design literature that this creative currency is one of the first to be de-valued through processes of routine in many design practices (Dorland, 2009; Lasky, 2012). Also evident was the belief that sustainable design and ‘good’ design were mutually exclusive, a barrier that could be overcome through broader education on what design for sustainability entails and what it is capable of achieving.

Accolades for the creation of great work can form part of a designer’s creative reputation, which in turn gains them greater respect from their clients. This respect can add value to the design process, acting as a platform from which the designer might leverage greater creative freedom or a bigger budget. Without this leverage, the designer can become confined to a space that is constantly pressured by considerations of time and money. Reflecting on the interviews also revealed a sense of fear or trepidation felt by designers who believed that practicing with the principles of sustainability could also impact their ability to create ‘great work’, by imposing limitations on their aesthetic. Interestingly, feelings expressed here were similar to those evoked by the limitations of client budgets, suggesting that the decision to avoid sustainability is underpinned by the perception that sustainability is about ‘things’ that could impose additional costs onto an already-strained budget and was therefore ‘too hard’ to contemplate or include.
Conclusion

Analysing contemporary communication design practice reveals the legacy of a long-term professional investment in outdated approaches that are more narrowly tied to routinized practices and immediate material outcomes. While the rapid evolution of digital technology is reshaping and disrupting this space, communication design practice remains entrenched in old ways of working, and the evolution towards more strategic modes of practice is somewhat slower than is required. Practitioners are knowledgeable yet underpowered to affect real change, and a routinized ‘standard practice’ tends to maintain this status quo.

There are untapped opportunities for overlapping methods from print and digital that are underpinned by strategy, but until methods that consider environmental and social sustainability become integrated into the norms of practice, communication design will most likely remain unsustainable in its focus and outcomes. Reviewing the literature and reflecting on interviews with Australian practitioners reveals that a broader understanding of sustainability is needed if it is to take on any kind of significant role in communication design practice. Engaging in deeper collaborations and repositioning the designer from resource to expert holds potential in creating approaches to sustainability that extend beyond making or using ‘greener things’.

The ever-growing network of specialisations and niches within communication design also open up opportunities for deeper strategic engagement and collaborative approaches that would require relationship building and extended thinking; beyond ‘things’, beyond aesthetics and beyond profit. Systems thinking and design thinking can provide structure and space for a broader, richer consideration of sustainability; strategy could be harnessed to better align projects and their potentially sustainable outcomes. By celebrating difference, appreciating unique skillsets and synergistic flows, the use of these lateral thinking processes along with reflective practice can be targeted towards sustainable solutions. To fulfill the role of communication design more completely, designers must recognise the role that collaboration plays in strengthening designer positioning, and focus on outcomes that facilitate a shift from ‘things’ towards more interactive forms of communication. The ‘wicked problems’ of sustainability require clever solutions, and through deeper engagement with the principles of design for sustainability there is a clearer path for communication designers to tread in order to create significant change.

**Niki Wallace**

Niki Wallace is an Australian-based communication designer, illustrator and copywriter. Her sustainable design practice provides unique personalised creative services that intersect print and digital design, and has recently begun to embrace elements of interactive/service design. She is a PhD candidate at University of South Australia with a research interest in sustainability for communication design where she is investigating sustainable design methods that could help dematerialise communication design through collaborative approaches underpinned by design and systems thinking. Niki is an early career academic and strives to live a zero waste lifestyle both professionally and personally; her personal zero waste experiences are also shared on her blog, Almost Zero.

**Robert Crocker, D.Phil (oxon)**

Robert Crocker teaches the history and theory of design and design for sustainability in the School of Art, Architecture and Design at the University of South Australia, where he is currently Deputy Director of the China Australia Centre for Sustainable Urban Development. Beginning his academic career as a historian of early modern science and
philosophy, he became interested in social and environmental sustainability whilst working as a volunteer for a local pedestrian advocacy group in the 1990s. This led him to develop an interest in other aspects of social and environmental sustainability, and particularly the role of consumption behaviours and systems and their technologies in generating our present environmental crisis. His research focuses on the escalating role of consumption and consumerism in the production of wastes, pollution and emissions, and the designer’s critical role in solving this ‘wicked’ problem.

A Design for Service (DfS) approach has been linked with impacts that significantly alter touchpoints, services and organisational culture. However, there is no model with which to assess the extent to which these impacts can be considered transformational. In the absence of such a model, the authors have reviewed literature on subjects including the transformational potential of design; characteristics of transformational design; transformational change; and organisational change. From this review, six indicators of transformational change in design projects have been identified: evidence of non-traditional transformative design objects; evidence of a new perspective; evidence of a community of advocates; evidence of design capability; evidence of new power dynamics; and evidence of new organisational standards. These indicators, along with an assessment scale, have been used to successfully review the findings from a doctoral study exploring the impact of the DfS approach in Voluntary Community Sector (VCS) organisations. This paper presents this model as a first-step to establishing a method to helpfully gauge the extent of transformational impact in design projects.

Keywords: Service Design, Organisational Change, Transformational Change, Voluntary Community Sector.

Introduction

Researchers have identified that designers’ roles have expanded over the last decade from the creator, to those of facilitator, educator and entrepreneur (Yee, Jefferies, & Tan, 2013, p. 233). These shifts have also led to a change in the types of outcomes that result from using design to consider a service experience; as a service acts as a platform for action, the design activity can incite transformations on personal, organisational and societal levels (Burns, Cottam, Vanstone, & Winhall, 2006; Manzini, 2011). The transformational potential of services stems from their entrenched and dispersed positions in social systems, thus having the potential to impact individuals, families and communities by suggesting and encouraging new behaviours (Ostrom, 1996). However, it is only in contemporary literature that the transformative powers of Service Design have been formally recognised, with discourse exploring design’s role in inciting fundamental change in organisations (Bate & Robert, 2007; Junginger, 2006; Junginger & Sangiorgi, 2009), communities (Blyth & Kimbell, 2011; Thackara, 2007), and policies (European Commission, 2009; Rudnick, Miller, Kimbell, & Philipsen, 2010).

Design have been formally recognised, with discourse exploring design’s role in inciting fundamental change in organisations (Bate & Robert, 2007; Junginger, 2006; Junginger & Sangiorgi, 2009), communities (Blyth & Kimbell, 2011; Thackara, 2007), and policies (European Commission, 2009; Rudnick, Miller, Kimbell, & Philipsen, 2010).

The terms design and transformation have often been linked; Simon’s (1969, p. 55) definition of design as “the transformation of existing conditions into preferred ones” is a pertinent example. However, it was not until Burns et al.’s paper in 2006 that this area of design practice was proposed as a separate discipline; Transformation Design. Since then, a growing number of UK consultancies have described themselves as ‘transformers’, be it of
people (Snook, 2014), public services (Innovation Unit, 2014), strategies (Uscreates, 2014), or organisations and communities (Taylor Haig, 2014). Similarly, Yee, Jefferies and Tan (2013) collected 42 stories on the changes in design practice and identified that many interviewees talked about their role in transforming existing conditions, into preferred ones (Yee et al., 2013).

Despite this growing recognition of the transformational potential of Design, it has been difficult to quantify this value in these social contexts. There has been a conscious effort to attain financial impact from design programmes (Design Commission, 2013; Design Council, 2010), but the complex nature of service value can make it difficult to track the significance of a design intervention in monetary terms (Lievesley & Yee, 2011). As a result, case studies are the most common format used to explicate the value of the approach.

In a recent doctoral inquiry exploring the value of a Design for Service (DfS) approach to Voluntary Community Sector (VCS) organisations (Author 1, 2015), the approach was introduced and applied within three VCS organisations in succession for a two-month period. In each organisation, data on the impact and perceived value of the approach to a range of stakeholders was captured during, immediately after, and in the year following the engagement. Stakeholders in Charities A and C reported outcomes that they considered to be ‘transformational’ as a result of using the DfS approach, whereas Charity B did not.

Without an existing model to measure the extent of transformation in design projects, it was not possible to establish if the perceived transformations in Charities A and C could be validated. Therefore, the authors conducted a literature review on subjects, including: the transformational potential of design, characteristics of transformational design, transformational change and organisational change. From this review, six indicators of transformational change in design projects were identified and used to gauge the extent of the transformation in each project setting.

This paper discusses the case study findings in relation to these six indicators, and proposes the model as a first-step in establishing the extent of the impact of design interventions in lieu of more traditional KPIs.

**Research Study Methodology**

This paper draws its data from three case studies conducted as part of a Doctoral Inquiry where design was used for the first time to explore a VCS organisation’s issue. The study adopted Action Research (Lewin, 1946; McNiff & Whitehead, 2011) and an exploratory case study method (Yin, 2003) as the focal research methodology (Author 1, 2015). In each of the three charities, the designer worked with a variety of stakeholders; staff and volunteers who administer services directly to clients; middle management; and executive leadership. The design activity and its impact was captured though a mixture of: project meeting recordings, reflection-on-action documentation and semi-structured interviews conducted by an independent researcher to ensure honesty and transparency.

The three organisations, along with a brief description of the design activity and outcomes directly attributed to it, are described below in Table 1:

**Table 1: A description of the charities, the design activity and the outcomes.**
**Charity A** is a local organisation that is part of a UK federation (Network A). They provide mental health services across three boroughs in North East England.

<table>
<thead>
<tr>
<th>Design Activity:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Co-design new ‘empowerment’ system that supports service users to progress on from the charity’s provision, including a partnership service and associated touchpoints.</td>

<td>- Design research insights report submitted as part of a successful £190k grant application.</td>
</tr>
</tbody>
</table>

**Charity C** is a national charity based in North East England. Their mission is to engage children in reading and they offer a variety of services, both directly to the public and through educational institutions, which address this aim.
- Conducted design research into the visitor experience in their building, communicated in a series of experience maps and a report.
- Used findings to run idea generation workshops with staff and co-design and prototype new touchpoints.
- Research findings contributed to two successful grant applications totalling £1.9m.
- Maps used to train new staff on the diversity of customers and their varying needs.
- Seven of the nine prototypes improved the visitor experience, resulting in £50k increase in earned income, as well as better customer feedback. They are still in use in the centre.

To establish a way to measure the extent of transformation in each case, a literature review (Robson, 2011) was conducted. The results of this are outlined in brief below:

**Transformational change in design projects**

Design research that discusses the potential for the practice to result in transformation often reference Organisational Change literature to define exactly what is meant by the term (Junginger & Sangiorgi, 2009; Sangiorgi, 2011).

Sangiorgi (2011) transposed service design outcomes onto Levy’s (1986) model of second-order change; that which changes the “metarules” (the rules of rules) of the organisation (see Figure 1).

![Figure 1](image-url)
She purported that for Service Design to be used in a transformational way, a design team cannot just produce improved service interactions or design interventions, but must challenge the fundamentals of an organisation’s behavior (Junginger and Sangiorgi, 2009; Sangiorgi, 2011). Likewise, Burns et al.’s (2006, p. 21) seminal paper on Transformation Design describe it as “creating fundamental change”. Wetter-Edman (2011, p. 69) suggests that transformation results in behavioural change, whereby there is a lasting impact on the organisation and/or community, and its stakeholders. It is the more significant change in all of these models, where the system itself is altered, that is now commonly accepted as transformational change.

**Transformation Design models**

Design discourse has attempted to generate knowledge on the use of the practice to effect transformation. Burns et al.’s (2006, pp. 20–23) ‘call to action’ first presented six characteristics that are prevalent in all transformation projects:

1. Defining and redefining the brief
2. Collaborating between disciplines
3. Employing participatory design techniques
4. Building capacity, not dependency
5. Designing beyond traditional solutions
6. Creating fundamental change

They suggested that these characteristics required designers to work in new ways to “leave behind not only the shape of a new solution, but the tools, skills and capacity for ongoing change” (Burns et al., 2006, p. 21). Building directly on Burns et al.’s (2006) definition of the discipline, Sangiori (2011) defined seven key principles to transformational engagement drawn from transformative practices in Design, Organisational Development and Community Action Research (see Figure 3).
Although both of these papers have suggested what comprises a transformational design process, the relative infancy of design practice with this aim means that there are no defined models that describe how to identify if the practice has had a transformational impact i.e. at what point organisational change is perceived to be transformational organisational change. Following the analysis process used by Denis et al. (2011) to identify themes with which to assess healthcare system transformation, the authors have reviewed literature and defined a model to measure transformational impact in a DfS project.

Drawing on studies of transformational change in organisations or communities, six indicators of transformational change have been identified. An early iteration of these indicators can be found in the co-authored paper (Author 1 and 2, 2012). These indicators, based upon an updated review of Design literature in this context, are presented below, before describing how these were used to analyse the case study data.

**Indicators of transformational change in DfS projects**

**Transformative design objects**

In healthcare systems, changes in the services provided, or in their mode of delivery, that positively impact on the service user are considered indicators of transformation (Ferlie et al., 1996). Kimbell (2011, p. 49) found that the aim of a designer’s engagement was to “create and develop proposals for new kinds of value relations within a socio-material world”. In a transformational context, such ‘value relations’ are a means of altering the way in which organisations connect to individuals, and are often non-traditional (Burns et al., 2006).
The presence of non-traditional design outcomes that alter the way that an organisation, system or service interacts with its user should therefore be considered an indicator of transformation. These objects should not just be created, but be used and valued as a design outcome to support this claim (Kimbell, 2011a; Wetter Edman, 2011).

A new perspective

Thackara (2005) suggests that a new perspective is necessary to fundamentally change the status quo. Literature suggests it is design’s human-centered focus that can provide this new perspective that acts as a platform for organisational change (Blyth & Kimbell, 2011; Edvardsson, Gustafsson, & Roos, 2006; Gloppen, 2011; Junginger, 2006; Kimbell, 2011). A designer often supports stakeholders to consider an issue holistically in order to correctly frame the problem they want to address (Burns et al., 2006; English, 2006). This act of reframing can be viewed as a design method employed to bring about change, but the ability for stakeholders to then do this for themselves is seen as an indicator of gamma change (Bartunek & Moch, 1987; Junginger & Sangiorgi, 2009; Levy, 1986; Sangiorgi, 2011). Evidence that an organisation has adopted a new way of viewing the services they offer or the challenges they face would therefore suggest that there had been a transformational outcome.

A community of advocates

Transformation, like service, is perpetual and indeterminate therefore a community of advocates is needed to continue to realise the change (Wetter Edman, 2011). A designer’s role should be to facilitate the formation of a community who can provide the encouragement and permission for the DfS approach to permeate into other areas of the individual’s or organisation’s practice (Billings, 2011, p. 23; Manzini, 2011). Han (2010, p. 10) describes this as a ‘Community of Service’, and suggests that it is an intangible but essential outcome of Service Design practice, as it is this community that will deliver and consume the resulting change after the designer’s engagement ends.

To this end, evidence of a community of project stakeholders who are advocates of the DfS approach in the organisation should be viewed as an indicator of a transformational outcome.

Design capability

In organisational change discourse, Greenwood and Hinings (1996, p. 1039) suggest that an enabler of ongoing radical change is capacity for action, whereby organisations possess the ability to “manage the transition” between the previous state, and desired state of change.

Much design research suggests that this requires a further shift in the designer’s practice; they must go beyond the idea of designing service solutions with stakeholders and view themselves as capability builders (Burns et al., 2006; Manzini, 2010; Tan, 2012). In her model of transformational principles (see Figure 3), Sangiorgi (2011) suggests that building this capacity should be the first step in a designer’s work, to engage them in tools and methods that help them to deal with complex issues and changing contexts as part of daily activity. Han (2010) on the other hand, suggests that capacity building happens as a byproduct of the participatory approach, and knowledge is gained throughout the design process.
Evidence that advocates of the approach are able to apply it themselves would therefore be a further indicator of transformational change (Han, 2010; Manzini, 2011).

**New power dynamics**

Organisational Change research suggests that the reconfiguration of power and relationships should also be used to assess the transformation in an organisation (Romanelli and Tushman, 1994; Ferlie et al., 1996). Design literature talks in particular about the redistribution of this power amongst the community (Manzini, 2011; Sangiorgi, 2011; Tan, 2012). For communities to be empowered to co-design and co-produce their own services and systems (Brown, 2009; Burns et al., 2006; Sangiorgi, 2011), permission and a shift in power is required to enable this contribution to be made and acted upon (Thackara, 2005; Sangiorgi, 2009; Design Commission, 2013).

In the VCS organisation, a change in the level of permission, job remit, and a more empowered community in relation to service development would all suggest that a transformative impact has occurred.

**New organisational standards**

Burns *et al.* (2006) suggest that the final characteristic of a transformation design project is that they fundamentally change the community’s or organisation’s culture. As has already been outlined, literature states that without this change to the system itself, a change cannot be considered transformational (Levy, 1986; Junginger and Sangiorgi, 2009; Sangiorgi, 2011).

In Organisational Change, Ferlie *et al.*’s (1996) model for assessment of transformational change in healthcare suggests that “the creation of new organizational forms at a collective level” and “the development of a new culture, ideology and organizational meaning” are indicators of transformation. Design discourse suggests that a practitioner must not only create a community of designers with a new, shared, way of thinking but also co-create a new vision for the organisation with structures that support this new organisational worldview (Manzini and Jegou, 2003; Junginger and Sangiorgi, 2009; Tan, 2012).

Thus, new organisational standards, including policies, aims and visions, should be considered evidence of transformation in the setting.

**Measuring the extent of transformation**

The literature review established six indicators that can be used to signify meaningful transformation at an organisational and community level; evidence of non-traditional transformative design objects; evidence of a new perspective; evidence of a community of advocates; evidence of design capability; evidence of new power dynamics; and evidence of new organisational standards.

Following the initial analysis of the case studies, these six indicators have been used to gauge the level of transformation exhibited in each of the three cases. A scale ranging from zero to five was created to grade the level of transformation in relation to these indicators, with zero meaning no evidence, and five representing complete transformation. To enable
accurate scoring, a guide was created detailing the type of evidence required for the minimum (1), mid (3), and maximum (5) score for each feature (see Figure 5).

Evidence of transformative design objects:
1 = a single design object in use that alters the way the organisation relates to some stakeholders;
3 = a series of design objects in use that alters the way the organisation relates to some stakeholders; 5 = numerous distinct designed objects in use across various services/offerings, that alters the way the organisation relates to all of its stakeholders.

Evidence of a new perspective:
1 = a new way of viewing a challenge or service that has influenced behaviour on a limited number of occasions;
3 = a new way of viewing challenges, services or a system that has been applied in certain situations; 5 = a new way of viewing challenges, services and systems, applied consistently to all decision making.

Evidence of a community of advocates:
1 = one advocate of the DfS approach and some sharing of the approach within their organisation; 3 = one or more advocates of the DfS approach, with some sharing of the approach within and outside of their organisation, and the intention to engage DfS expertise in the future; 5 = numerous DfS advocates, extensive sharing of the approach within and outside of their organisation, and the engagement of DfS expertise.

Evidence of design capability:
1 = one stakeholder who is able and confident to use one or more design tool(s) to consider a specific challenge;
3 = one or more stakeholders who are confident and able to use several design tools to consider a specific challenge;
5 = a group of project stakeholders that are confident and able to use a plethora of design tools to consider a range of challenges.

Evidence of new power dynamics:
1 = one stakeholder who has been more involved than they have been previously, in the development of a service or system, on at least one occasion;
3 = one or more stakeholders who are more involved than they have been previously, in the shaping and development of services or systems, on a regular basis;
5 = a group of project stakeholders that are more involved than they have been previously, in the shaping and development of services or systems, and it is now part of their job description to do so.

Evidence of new organisational standards:
1 = new policies and procedures for one or more services;
3 = new policies, and a new vision or aim for one of the organisation’s services or systems; 5 = new mission, vision, aims, and policies for the organisation and its services.

Figure 4: A scale to guide the scoring of the extent of transformation in the case study

These guides were used to consider the data collated throughout the case study, but in particular the post-collaboration interviews, which tracked the design outcomes over time. Only outcomes directly attributed to the design activity were considered during this process.

As the scores were derived from the statements made by the project stakeholders, it could be argued that there may have been some bias or overstatement in order to improve the perception of the charity. However, as the participants were unaware of how this data would be specifically used, or the features against which they would be measured (none of the questions asked referred specifically to any of the six indicators), the data should be considered accurate. Moreover, as it is the VCS organisation’s perception of DfS outcomes by which any future engagements would be measured, their viewpoint, regardless of accuracy, should be considered as appropriate data. However, as this scoring process was
based on data gathered during and up to 12-months post-collaboration, it only provides a snapshot of the potential change, as transformational outcomes are ongoing and continuous (Greenwood & Hinings, 1996; Holmlid, 2007).

**Applying the scale**

To minimise the potential for bias, an independent design researcher undertook the same process. They were provided with the anonymised data interviews for each charity, which included interview transcripts, meeting notes and reflection logs. They were also provided with the scales to guide the grading process and a blank copy of a diagram on which to mark their ratings. The researcher completed the same activity as the authors in isolation, before comparing our respective results (see Figure 5 for the second markers results).

![Figure 5: Scanned copy of how the second marker rated each of the cases against the six indicators of transformation](image)

The Authors’ results only differed with the second markers on three points; the community of advocates score given to Charity A (by one point); the new organisational standards score given to Charity C (by one point), the transformative design objects score for Charity B (by one point). After reviewing the evidence for these indicators together, it was agreed that in relation to the community of advocates score, Charity A should be awarded the higher mark. Regarding the other two disparities, both charities were awarded the lower mark.

The agreed scores for each charity against each of the six indicators of transformation can be viewed in Figure 6.
Figure 6: Diagram that shows how each of the cases has been rated against the six indicators of transformation.
Discussion

Transformative design objects

Charity A – 4; Charity B – 1; Charity C - 4

Charity A and C have both scored four out of five for evidence of transformative design objects. In Charity A, the design activity resulted in several new job roles, Empowerment Workers, which altered the way that the organisation engages with its service users. There is now an impetus on supporting people to create new routines and adopt new roles in their local community, in order to progress from Charity A’s provision. Furthermore, the organisation also uses a ‘partnership personal plan’, co-designed to enable their service users to set goals and keep track of the progress they are making in improving their mental health. This series of transformative design objects has altered the way the organisation supports its customers, placing it above three on the scale. However, the transformative objects have not yet permeated into other service offerings, such as counselling, preventing Charity A from obtaining a five on the scale.

Similarly, Charity C’s stakeholders reported that they also had new touchpoints in place that had altered the customer’s experience. Seven out of the nine prototypes created in the collaboration were still in place, including a new sticker system, which allowed staff to identify if they were day visitors or annual pass holders, and thus relate to customers in a more tailored way. Although currently the designed objects only impact on visitors to the centre, there are also plans to retrain staff to provide a performance that relates to every exhibition, which would impact on all customer types, including the work they do in schools. If this were to happen, it could be argued that Charity C would then reach five on the scale, however as it stands, the limited reach of the transformative design objects places them at a four.

In contrast, Charity B has scored just one on this scale; having a single transformative design object in use that alters the way the organisation relates to some stakeholders. A newly designed membership system changed the way that customers consume some of the services, impacting on the health and fitness offerings in particular. However, there have been no subsequent changes to the membership material or job roles. Furthermore, the changes have had a more profound impact on the customers in receipt of social welfare benefits (who can access more services at a reduced price) than any other user group. The single transformative design object, coupled with a limited benefitting stakeholder group, means the transformation can only be ranked at a one on the scale.

A new perspective

Charity A – 5; Charity B – 2; Charity C - 5

Charity B’s highest grading comes on evidence of a new perspective in the organisation, where they have been awarded a rating of two. In the post-collaboration interview, the CEO described that the charity had a new way of viewing both the membership system, resulting in a new customer care department, and the building challenge, resulting in an alternative plan for the use of the building. However, there had been no significant changes to their services or systems, which keeps them at the lower end of the scale.
Conversely, there is evidence in Charity A of a consistent application of a new perspective that they attribute to the design work; “the ripples from [the engagement] have gone through the whole organisation” (CEO, Charity A). The permeation of this new perspective can be seen in their revised policy towards funding, where grants and commission need to align with the precise needs of their beneficiaries, and recruitment, where creative skills are considered alongside mental health expertise. As a result of their affirmation of a new organisational culture, and indications of a consistent application of this more user-focused practice, the charity has been placed at a five on the scale.

Likewise, the data collated in Charity C also places them at a five for evidence of a new perspective. The CEO noted that staff members, in particular front-line workers, were now looking “through the other end of the lens”. There was evidence that this new perspective had been applied not only to services, but to consider the systems within the organisation. In particular, the research undertaken as part of the collaboration has underpinned the charity’s new focus on valuing the social aspect of the experience they provide as equal to the educational facet. Their bookshop was reconfigured to reflect this, providing more space for parents and children to listen to and tell stories, and they created an indoor picnic space to provide further opportunities for social engagement.

Community of advocates

Charity A – 5; Charity B – 1; Charity C - 5

Charity A and C have both shared DfS practice within their organisation, with the former including it in their staff away day, and the latter inviting a university’s Design department to present to staff. Both Charity A and C shared their experience of the practice with external stakeholders; Charity C have detailed the work in their subsequent successful funding applications, whilst Charity A’s CEO has presented to Network A’s CEOs. Charity C’s recruitment of a university Design department to run a workshop can all be considered evidence of DfS engagement, which elevates them to a five on the scale. Charity A have also subsequently engaged with other Design teams, which can also be viewed as further use of the process, giving them the maximum score.

In contrast, Charity B have only scored a one on this scale, as there is one advocate of DfS, and limited evidence of sharing the approach within their organisation. Only the CEO now remains at the charity, however, even at the six-month interview when three of the project stakeholders were still in post, there was no suggestion that any additional dissemination had taken place.

Design capability

Charity A – 3; Charity B – 0; Charity C - 3

When considering the design capability at Charity B, there was no evidence available to award any points. The analysis of the project activity and the post-collaboration data shows that none of the project stakeholders express any ability to use design tools. Whilst the CEO described adopting a more engaging approach to consultation, he did not utilise any design tools to support this. It is thus considered evidence of a new perspective, as opposed to design capability.
Conversely, Charity C have continued to use the same activities undertaken during the engagement to consider and improve the experience for visitors; “[the marketing team is] using the service design methodologies to observe the way that people are using the space”. Further evidence can be seen in the management team’s use of the personas in the customer experience maps created as part of the design activity to help them think about spaces in the building from the perspective of these different characters. However, the organisation has not used any of the design tools to consider different contexts or challenges than those tackled during the collaboration, which means that Charity C achieves a three out of five for this indicator.

The same level of design capability is exhibited Charity A, with their use of the design tools being encouraged, but not universally applied. Several project stakeholders have used a design toolkit created during the collaboration to consider particular project challenges, but feel that they do not have the capabilities required to undertake a complete design process without support.

New power dynamics

*Charity A – 3; Charity B – 0; Charity C - 4*

Charity C exhibited the greatest amount of evidence relating to the redistribution of power. They have continued to actively involve their front-line staff in the improvement of the customer experience in a way they had not done previously. As a result, staff are now contributing to challenges that are both within, and outside of, their remit. However, the organisation has not endorsed the use of design by including it in any job roles, which limit the charity’s score to a four on the scale.

Likewise, Charity A have not formalised design into any of their staff posts, but they have reported a sense of empowerment in some of the project stakeholders. For example, the CEO said the Business Development Manager now takes “a very integrated approach” to writing bids, involving more stakeholders in that process and as a result, she now has a “closer relationship” with various departments. The Wellbeing Manager has now become more of a challenging figure to the organisation, using her new way of viewing things to question the charity’s practice. Both developments can be viewed as indications of new power dynamics, but as the evidence relates to their existing job roles and remits, it places the charity at a three on the scale. As with design capability, there was no evidence that Charity B had seen any redistribution of power since the collaboration, resulting in a score of zero.

New organisational standards

*Charity A – 5; Charity B – 1; Charity C - 3*

Only Charity A altered their mission and vision as a result of the engagement; “we work with you as a person, not a diagnosis or a problem or set of problems or an illness”. Along with the previously described new funding policy, the wellbeing services’ policy have also been updated to reflect the new organisational focus on progression and person-centred care. The extensive evidence of new organisational standards in Charity A has resulted in the maximum score of five.
Charity C has only achieved a rating of three for evidence of organisational standards. This can be viewed in the way that the organisation now engages staff cross-departmentally to consider the experience that is offered, providing front-line staff in particular with the opportunity and permission to make changes to the service. However, none of these standards have impacted the mission and vision of the organisation, remaining at a service level.

Again, Charity B has scored significantly lower, achieving a one on this scale. This mark was awarded for the new pricing policies in relation to the membership system, with the new customer care department also underpinning the evidence of new policies and procedures for one or more services. However, there were no further changes to policy, aims, mission, or vision of the organisation, or its services and systems, preventing it from achieving a higher rating.

**Conclusion**

This paper has shown that there is no specific model for measuring the level of transformation as a result of design activity, even though designers are increasingly inciting transformational change. As such, a review of existing research on transformation design and related subjects has been conducted to establish six indicators of transformational change in a design project: evidence of non-traditional transformative design objects; evidence of a new perspective; evidence of a community of advocates; evidence of design capability; evidence of new power dynamics; and evidence of new organisational standards.

The model has been used in this study to analyse the extent of transformation in the cases. This independently-validated process has shown significantly greater evidence of second-order change in Charities A and C than in Charity B. The scores of three or over in all of the indicators of transformation for both Charities A and C confirm the project stakeholders’ view that the design activity resulted in changes to the organisations’ culture. Conversely, in Charity B the low scores of two or less across the model show the collaboration only resulted in service interaction level change.

The six indicators model builds on those offered by Burns et al. (2006) and Sangiorgi (2011) to suggest how design projects could be evaluated to establish if they have resulted in a transformation, regardless of whether they have been set-up with that intention. Whilst this paper, nor the model, interrogate why those disparities in scores exist, it does highlight patterns (such as evidence of new perspectives being higher in all three charities) that can be used to begin to consider these.

This model is proposed as a first step in establishing a way in which the Service Design community could examine the outcomes of DfS projects in the future. However, further research is needed to understand the applicability of the indicators to other projects and how the model could support work within these contexts.

Innovative Handle Design and Evaluation of Woks for Middle-Aged and Elderly People

Fong-Gong Wu, Yu-Chi Lin, Hsiao-Han Sun, National Cheng Kung University, Tainan, Taiwan, fonggong@mail.ncku.edu.tw

Abstract

With the enhancement of medical technology and human living standards, the world is showing a trajectory towards an aging society. The elders generally suffer from degeneration, which may cause problems in their daily lives. Aging has since become a major issue of scientific researches.

Elders in Taiwan mostly live alone or with a partner. Because eating out is not a habit, cooking often plays an important role in their lives. Due to the degeneration happening to their bodies, the danger during cooking activities increases. Therefore, it is necessary for them to seek help from assistive devices.

In this research, we will make assistive design models that help elders use woks. The designs are for the task we have chosen from our investigation. We will also evaluate the effect of the aids objectively using the EMG system, and collect the iEMG value for evaluation. The iEMG values were collected from four muscles (FDC, FCR, Biceps and Deltoids). Eight middle-aged participants who will become elders in the near future were invited to participate in the experiment. Four design solutions were chosen from seven working models. The design solutions were all helpful to the task, and the performances of the stove design solutions are significantly better than the original wok. The degrees of hand trembling while performing tasks were also measured, however the differences were not significant.

Keywords: Handle Design, Wok, Middle-Aged, Elderly people, Ergonomic Design

Degeneration is an inevitable problem associated with aging. The muscle mass of elder people will reduce 25% to 45%, while the muscle endurance will reduce about 20%. Furthermore, the muscle strength and muscle area will also reduce (Harit and Dolsak, 2014; Hyatt, 1990).

Due to their living habits for decades and the inconvenience in mobility, elder people do not eat out very often. Instead, they prefer cooking for themselves. Kitchen tasks involve many actions that require physical abilities. Also, associated with the danger accompanying high temperature, we need to place a focus on kitchen tasks. Due to the degeneration of elder people, they cannot deal with all the kitchen tasks smoothly. The decrease of upper body functions makes it difficult for elder people to operate kitchenware, rotate grips and perform certain fine actions (Holt & Holt, 2011). Concluding all the reasons mentioned above, it is necessary to come up with assistive devices that help elder people deal with daily kitchen tasks.
In this research, we have visited the homes of several elder people. We found that elder people tend to work with traditional kitchenware, especially with woks, saucepans and stockpots. Traditional kitchenware appears to be durable but heavy. Elder people are generally frugal because of their life habit during the war era. According to our observation, most of the elder
people are still using the kitchenware from their old times. In addition, when elder people were younger, they had to cook for the whole family, so they tend to choose bigger woks or stockpots. But after their children grew up and left home, the heavy and old-style kitchenware remains in use; they are reluctant to disuse anything that still works, even if there are better, newer designs (Raven, 2006). Many elder people are still using big woks that can cook for four to five people. The main purposes of this research are listed below:
(1) To design aids for traditional woks and saucepans.
(2) To evaluate the aids designed in this research by electromyogram (EMG) and subjective questionnaire for assessment of results.

1. Observation and Literature Review

In this research, wok tasks, which involve a lot of hand motions, will be focused. When holding things, the force is mainly from our fingers and wrists (Goislard de Monsabert, Vigouroux, Bendahan, & Berton, 2014). With that said, discussing the aging of hand muscles and joints will help the research. We will observe and analyze the behaviors to uncover any common problems and find solutions to them.

There are two holding styles: (1) grip and (2) pinch. The serial analyses of these two motions are mentioned below.

(1) Gripping

1. Placing fingers
   - Lumbrical muscles and extensor digitorum muscles.
2. Approaching
   - Finger flexor muscles control the bending of fingers; extensor carpi ulnaris and flexor carpi radialis fix the angle of wrist.
3. Gripping in static state
   - No movements at this stage. Muscles involved are isometric.

Table 1 Serial analysis of gripping

</tr>
</tbody>
</table>

Kitchenware includes a lot of hand tools, and due to the high temperature of cooking tasks, gripping stably is very important in order to reduce the risks of possible accidents. Table 1 and Figure 1 are the serial analysis of gripping. We can see that the muscles involved are mostly located in the forearms. Muscles in the forearms are fine and complicated.

(2) Pinching

Comparing to gripping, the muscles working for pinching are finer and more complicated. Pinching is to hold objects with pulps, and is mostly used to hold finer and smaller objects, such as chopsticks and clips. We also use pinching to deal with some special cooking tasks like pinching the edge of a pot of hot soup.

Table 2 and Figure 2 are the serial analysis of pinching. We can see that the ways the muscles...
work are pretty much the same with that of gripping with minor differences.

<thead>
<tr>
<th>Motion Description</th>
<th>Working Muscles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opening</td>
<td>The number of fingers open depends on the shape of the objects and the intention of the action. Thus, there are unlimited combinations between lumbral muscles and extensor digitorum muscles.</td>
</tr>
<tr>
<td>Placing fingers</td>
<td>Unlike gripping, when pinching, thumb is always on the opposite side of other fingers, and objects will be held by the first knuckles of fingers.</td>
</tr>
<tr>
<td>Approaching</td>
<td>Finger flexor muscles control the bending of fingers; extensor carpi ulnaris and flexor carpi radialis fix the angle of wrist. Usually, index fingers, middle fingers and ring fingers stay curved, and little fingers might be curved or straight.</td>
</tr>
<tr>
<td>Pinching</td>
<td>No movements at this stage. Muscles involved are isometric.</td>
</tr>
</tbody>
</table>

The analyses of Table 2 show that, regardless of the opening motion, the main muscles used when holding objects, with either the gripping or pinching motion, are the finger flexor muscles that bend our fingers and the extensor carpi ulnaris and flexor carpi radialis that fixes our wrists. In this research, tasks done with woks and pans will be our focus. When using such kitchenware, the main motion of our hands will be holding. Thus, when collecting EMG data for evaluation, the muscles mentioned above will be emphasized.

Because the muscle composition of forearm is complicated, our hands can do many fine motions. Besides the holding motion mentioned in the previous chapter, forearms can also perform rotating motions. Forearm rotates randomly when working in a kitchen, which means that there is not a standard procedure for the rotating motion. In that case, we list movements and muscles that are possibly involved, shown in Figure 3.

When working in the kitchen, we often have to lift objects. Biceps, brachialis, brachioradialis are mainly involved when lifting objects. Figure 4 shows the position of these muscles. When our arms flex, biceps provide the most power, and brachialis and brachioradialis do fine adjustments. When our arms flex with palm downwards, brachialis and brachioradialis bare an especially heavy loading.
In this research, we focused on woks and pans. Woks and pans have different forms of handles. In this section, handles will be emphasized to gain parameters for design.

Working with bending wrist for long periods will cause pain and chronic diseases, or even permanent damages (Tichauer, 1966). Grip force performs the best when wrists are kept central (Kadefors et al., 1993). Thus, it is important to keep wrists central when designing handles. In that case, the handle not only eases the pressure on wrists but also enhances the efficiency of work. Thickness influences the pressure on palms. Besides adjusting thickness, changing the shape of handles is also a solution to make gripping easier. Previous findings show that compared to cylindrical handles, people feel more satisfied with the handles that fit their hands (Lewis, 1993; Harih and Dolsak, 2014).

As for spatulas, to prevent subjects from touching the edge of a hot pan, a spatula with a 25 cm handle length and 25° lifting angle is suggested (Wu, 2002). However, the research did not change the form of spatulas, but only the sizes and angles. In this research, we try to develop innovative design solutions without the limitations to the existing forms.

2. **Method**

2.1. **Observation**

We invited a woman of age 81 to be the model for observation. Slow motion videos were recorded, and the result of the observation would be the foundation of the design process. The participant was asked to repeat the task we assigned for several times, and videos were recorded from behind the participant, as well as her left and righthand sides. Circle stickers will be placed on the joints of the participant as marks (shown in Figure 5), to help with the observation. Table 3 shows the details of the observation.

In this research, six people (with an average age of 25.6 years old) with design backgrounds were
invited to participate in the focus group process. Before the process, participants were asked to gain knowledge of our issue and background information.

There were two stages of the focus group.

(1) Observation:

Participants were asked to watch the three slow motion videos recorded during observation. The video was repeat continuously, and each participant was asked to share their thoughts on each video with other participants and to discuss amongst the group.

2.2. Focus Group

With the observation in the previous stage, participants would understand what the problems are. For the task we focused on, woks and stoves are involved. We separated the wok into handle and wok parts. Along with the stove, we have a total of three parts of the object. Participants were asked to develop ideas based on the problems they pointed out, and to propose solutions to
(2) Design Development

We chose three handles (thick handle, hollow handle and upright handle), one wok (anti-flipping wok) and three stoves (stove plate, rounded stove and stove stand) as our solutions. The reasons we chose these solutions are due to the feasibility and our technology limitations. Figure 6 are the final solutions of our aid design. Objects shown in the chart are composed for evaluation.

The concept handle models are made with PU foam. With the concept models we can make little adjustments to the handle shape so as to fit the hands. As for the sizes, Seo and Armstrong (2008) mentioned that if the hand optimal size is bigger than the handle diameter, which is the common situation for woks that are available nowadays, grip force decreases with decreasing handle diameter. Therefore, we made our model with a diameter bigger than common-found handles and try our best to fit the optimal sizes of hands. We then made 3D handle models with Solid Works. Working models are made by Up Plus 3D printer using ABS as our material. The thickness of layer was 0.2 mm, and the print speed was medium. Figure 7(a) is the wok used in this research. The diameter is 38 centimeters, and the weight is 1.5 kilograms. The handle is replaceable, so we can change the handles we printed to evaluate their effectiveness.

Figure 7(b) is the wok design. This structure is expected to make users avoid flipping the wok. Figure 8 is the illustration of how the wok is expected to work. Figure 8(a) is to make the dish lower than the stove. The height of the plate is 9 centimeters. Figure 8(b) is to add a circle base around the stove so that the wok can rotate smoothly along the base. The height of the base is 6 centimeters. Figure 8(c) is to provide a standing stand so that users can place the wok after they lift them in the air, which could make flipping woks easier to accomplish. The height of the stand is 18.5 centimeters, which should be approximately the same with the wok radius so that the wok would not knock against the stove while flipping. These three objects are aimed to help users accomplish the task without too much force.

Figure 7 (a) Wok and replaceable handles; (b) Wok design
In sum, table 4 is the list of all the design models from this research. Names are given to each model, and statements of each design concepts are also in the table.

2.3. Pretest

A pretest was performed to eliminate the models with unsatisfactory results. Originally, we had 3 handles, 1 wok and 3 stoves, a totally of 7 design solutions as our design development. For the pretest, we invited 7 participants to perform the task. Participants for the pretest were an average age of 23.5 (SD=0.957). Each participant was asked to perform the task for 8 sets, one for the original wok and stove, and the other seven for the 7 design solutions. Cookies are placed to simulate ingredients, and participants were asked to scoop up the cookies into an iron pot.

<td>To provide a standing stand so that users can place the wok after they lift them in the air.</td>
<td></td>
</tr>
</tbody>
</table>
Participants were asked to practice with all the design solutions for several times, so as to ensure that they fully understand how the aids work. When the participants can smoothly perform the task with all the aids, they were asked to fill out a questionnaire.

The questionnaire is a scale of subjective feelings towards the design solutions. For hand tools, Kuijt-Evers, Twisk, Groenesteijn, De Looze, and Vink (2005) proposed the CQH (Comfort Questionnaire for Hand Tools). The questionnaire asks participants to rate their feelings for the hand tools with Likert scale, so as to evaluate the subjective feelings. We selected some appropriate questions for our questionnaire to evaluate the handles designed.

The questionnaire is composed with positive questions and negative question. Participants were asked to answer all the questions in Likert scale. We calculated the average score of both positive (Pavg) and negative questions (Navg), and obtained the ratio of the two average scores.
(Pavg/Navg). The results are shown in Table 5. According to table 5, we can see the Pavg/Navg ratio of the 7 design solutions. The top four of the ranking (stove1, stove3, handle1 and handle2) was selected for the final evaluation.

2.4. Experiment

Four models were chosen from the pretest, and the evaluation of this research is the EMG data for using these models. Eight middle-aged participants were invited as the participants. Participants were asked to perform the task we chose from the questionnaire. This research aims to find out whether the aids help with the task or not and the change of muscle loading, so the data before and after equipping the aids will both be collected. After the pretest, we chose four solutions, including two handles and two stoves. With the original handle, a totally of five sets of experiments were conducted. Participants were asked to repeat the task three times for each set. The task was divided into three movements. For each set, 10 seconds for lifting the wok, five seconds for flipping the wok and 15 seconds for putting the wok back and rest. Thus, each trial of EMG data was 90 seconds long, and a total of five trials of data were collected from each participant. Figure 9 shows the correspondence between movements and the timeline. This specification is to make sure that participants do the same movements at the same time. In that case, comparisons from data to data would be more sensible.

Stability was also measured. Yan and Downing (2001) mentioned that stability is also a criterion of firm gripping. To measure stability, an app was applied to detect the position information.

Before the EMG measurement, participants were asked to fully understand what they were going to do. Due to the fact that these aid design solutions are innovative, participants may not know how to use these new designs from first sight, needless to say to manipulate the aids. In that case, participants were asked to practice for several times before the measurement. Data collecting did not start until the participants were fully aware of the aids and their tasks. The data of handles were compared with others from the handles, and data of stoves were compared with that of the woks. Since we only have two design solutions remained for each category after the pretest, we chose the better one from each category and combined them into a system.

(1) Participants

Eight participants were invited to the experiment (four males and four females). Participants were an average age of 51.25, right handed, and were all experienced with cooking. Participants
are healthy and have never suffered from hand diseases.
There are two main reasons for us to invite middle-aged participants rather than elder participants:

(a) Due to the muscle degeneration that happens to elders, it would be easier to collect accurate muscle data from middle-aged participants.

(b) Middle-aged participants will become elders in the near future. However, some musculoskeletal problems like trigger finger, tennis elbow and De Quatrain’s disease begin during middle-aged. The aids designed can also be considered as a prevention of their degeneration.

(2) Apparatus
(a) Electromyography (EMG)
The device used to measure muscle action potential is BioRadio 150 by CleveMed. The device is composed by a user unit, a computer unit, wires, electric patches and a computer with Windows operating system.

The muscle action potential signal are transmitted to the computer unit via Bluetooth. The computer unit is connected to a Windows operating system computer. The software of the device called BioCaptureshould is installed on the computer. The waveform of the muscle action potential signal are shown on the screen. After the data collection process, the data can be exported as a csv. File form, which can be opened by excel. The electrode patch is Medi-Trace 200 by Kendall. The Kendall Medi-Trace 200 series electrode EG200 is made with foam, adhesive gel and an Ag/Ag chloride conductor. It is latex free and 3.6cm in diameter (Danlee Medical Products, 2014).

(b) Short-focused projector
The projector is used to play a demonstration video on the white board. Mirrored output videos were played while participants perform their tasks. The videos were used to remind the participants of their tasks. In the videos, the demonstrator made cues for the participants to follow. This allowed us to control the tempo of tasks, which made it easier to analyze the EMG data.

(3) Environment Setting
The experiment was held in the Interaction Laboratory of Department of Industrial design, NCKU. The table height is 85 centimeters, which is the same with the standard stove height in Taiwan. On the left of the table is the computer for collecting EMG data, and all the design models are put on the table. On the top left of the white board is the user unit of the EMG device. Also, a demonstration video was played synchronously when the experiment was in progress. Participants were asked to follow the video displays. To allow the participants to imitate the movements and catch the tempo easier, the video was mirrored output. This is to enhance the compatibility (Sanders & McCormick, 1987) and avoid unnecessary mistakes. Fig 10 shows the situation of mirrored output video.
2.5. Evaluation of Design

The main evaluation of this research is via the EMG equipment. By comparing the data before and after the use of the aids from this research, we determine whether the design ideas were helpful.

The data collected by EMG equipment are numbers that cannot be analyzed directly. Therefore, the data have to be transferred into iEMG value by Matlab, and the iEMG value is then used to do statistical analysis. The original data has to go through six steps to be transferred into iEMG value.

3. Results

3.1. EMG Data Analyses of Handles
With the result of the description data shown in Table 6, FDS (Flexor Digitorum Superficialis) shows the easiest loading when working with the thick handle. Here we can see that both of the two design solutions performed better than the original one. The design solutions all eased the pressure of FDS. The sequence of the effect to FDS would be (from better to worse): Thick handle>Hollow handle>Original handle.

</table>

3.2. EMG Data Analyses of Stoves
The differences between the two stove design solutions and between muscles were significant (p<0.05). Also, mutual effect happened during the experiment. Table 7 shows the descriptive data of the experiments for stoves. A brief trend can be seen from the mean value which shows that the two stove design solutions are lower than the original one.

Table 7 Descriptive data for design solutions (stoves)

</table>
Table 8 is the LSD (Least Significant Difference) analysis among design solutions. By the one on one comparison among the stoves, we can see that the mean iEMG values of both two stoves were significantly lower than that of the original stove. As for the comparison between the stove plate and the stove stand, there was no significant difference. But according to the descriptive data shown in Table 8, the stove plate performed slightly better than the stove stand. This shows that the two stove design solutions did help the task significantly.

Further, with the result of the description data shown in Table 9, FDS shows the least loading when working with stove plate. Here we can see that both two design solutions performed better than the original one. That is to say, the design solutions all eased the pressure of FDS. The sequence of the effect to FDS would be (from better to worse): Stove plate > Stove stand > Original stove.

The differences of the FCRiEMG values between the original stove and the two stove design solutions are significant (p<0.05). The differences of the BicepsiEMG values between the original stove and the two stove design solutions are significant (p<0.05). Further, with the result of the description data shown in Table 10, Biceps shows the least loading when working with stove plate. Here we can see that both design solutions performed better than the original one. That is to say, the design solutions all eased the pressure of Biceps. The sequence of the effect to Biceps would be (from better to worse): Stove plate > Stove stand > Original stove.

3.3. EMG Data Analysis of Combination of Handles and Stoves

Through the comparison conducted, thick handle and stove plate performed better in their groups. Thus, we combined them together and run the same experiment process to see whether the combination works better. Table 11 is the description data of the four muscles. According to the description data (mean iEMG value), the combination of thick handle and stove plate did not show better performance than using the stove plate alone.

3.4. Subjective Questionnaire

Participants were asked to fill out the same subjective questionnaire as the one in the pretest. The results are shown in Table 12. The Pavg/Navg ratio all decreased for the four design solutions, which means that participants of the experiment were less satisfied with the design solutions than participants of the pretest. The rank among the design solutions also changed a little; according to Table 6, participants felt that hollow handle was better than thick handle.

4. Discussion

Since the design solutions of this research are all based on a traditional wok, we chose a wok with a changeable handle. There were two problems with the wok: (1) an awkward angle of handle. (2) Too heavy. As Figure 11 shows, an angle exists between the wok and the handle. This angle made the handles higher than expected, which made lifting more difficult for participants; they had to lift higher than they usually do. Moreover, the higher handle might keep the handles designed from performing their expected functions. More severe ulnar deviation happened, and Figure 12 tells why. Additionally, participants complained about the weight of the wok. These two problems might be the reasons why the iEMG value of FCR tended to be higher than other muscles measured.

The eight participants substantially performed the five-set experiment smoothly. With the demo video played in front of them, the motion tempo was well controlled so that the data collected could be compared directly. For EMG data collection, data of all male participants were collected successfully in one time. But for the female participants, the signals were not as strong and steady as the signals from the male participants’, which made the experiment sets re-run for a few times.

Figure 11 Awkward angle of the traditional wok
With all the situation and environment factors controlled, the factor that influenced the signal quality might be the difference between male and female. Generally, females have more subcutaneous fat, and this makes their muscles more difficult to show. Relatively, males not only have less subcutaneous fat but also stronger muscles. In that case, it was easier to place the electrodes at the right places when collecting data from males. However, weaker muscle performance may cause weak signals, and plus the cut off caused by subcutaneous fat, sometimes data were lost for a while because there was nothing measured.

Design solutions for handles are to change the way muscles works, and design solutions for stoves are to change working modes. From the highlights of the focus group observation, for the 17 highlights, changing the way muscle works were mentioned 13 times, and changing working modes were mentioned 6 times. These two principles took the first and second place among all the principles. From the description data of mean iEMG value, stove plate and stove stand apparently helped more than thick handle and hollow handle. This may be because when using stove plate and stove stand, participants did not have to lift a great range. Without the load of Biceps and fewer loads of FDS and FCR, the iEMG values decreased significantly. The result tells that changing working modes might be the more efficient way to help users when designing aids, which appears to be a little different from the highlights of the focus group observation. From the aspect of muscles, during the task of scooping ingredients into dishes, FCR loaded the most through the handle design solutions. Qin, Chen, and Dennerlein (2013) mentioned that the loading of FCR corresponds to ulnar deviation, which means that the design solutions of this research did not solve the problem of ulnar deviation. FDS took the second place of loading. Thus, we can say that the main loading of this task was on the forearms. According to the results, we can easily see that thick handle performed better than hollow handle, while stove plate performed better than stove stand.

5. Conclusion

All the design solutions helped with performance improvement of the task in this research. Among the four design solutions of this experiment, stove plate showed the most significant improvement. Besides the performance on EMG experiment, stove plate also got the highest Pavg/Navg ratio from subjective questions. Design solutions for stoves both performed significantly better than design solutions for handles. Thus, changing the working mode is the most efficient way of designing aids. Mutual effects happened to handles, and the loading of FDS decreased while the loading of FCR increased for both handles. This shows that the handles did help with the gripping movement, but did not help with the ulnar deviation. Future works can be focused on changing more parameters like handle diameters and angles to find the best size and shape for the handles.

Differences of hand trembling among all the design solutions are not significant, and this might be because the tasks performed in this experiment were not tiring enough to make hands tremble. Through this research, higher stove plate is strongly recommended. Higher plate for stoves not only helps with the task but is also better for tasks that require a high degree of concentration, especially for the stove related tasks that are associated with high temperature. Also, users do not have to bend down low to check the fire. Stove stand was also a creative solution that
significantly decreased the loading on muscles, but the process of hanging the stove onto the stand caused extra muscle loading. Despite the fact that stove stand performed worse than stove plate in EMG analysis, further adjustment and development may still be worthwhile.

Author Biography
Fong-Gong Wu

Fong-Gong received his BSE degree in Industrial Design from National Cheng Kung University (NCKU) in 1977, and MID degree from Syracuse University in 1985. He was an assistant designer at Sino Design Co. before joining the Cheng Kung Industrial Design Department in 1977. He was invited to be the secretary general of China Industrial Designer Association (CIDA)
(1989-1991). From 1989 to 1992, he was the chairman in the department of Industrial Design and the founder head of the Industrial Design Institute at NCKU. He was elected as a President of Chinese Institute of Design, Taiwan (2009-2011). He had been a visiting professor of Institute of Design, IIT, USA from Oct. 2008 to Feb. 2009, a visiting scholar of Comparative Media Studies, MIT, USA from April to July in 2009, the publisher of Journal of Design (THCI core) (in Chinese) and the publisher of International Journal of Design (SCI, SSCI, A&HCI) from 2009 to 2011. He now is the dean in the Planning and Design College, and a distinguished professor in department of Industrial Design at NCKU, and an executive board member of International Association of Societies of Design Research (IASDR). His research interests include ergonomic design and design philosophy.
Craft and Design for Sustainability: Leverage for Change

Abstract

Traditional craft has been relegated to the margins in modern culture, being perceived as out of step with technological, economic and societal progress. However, emergent research is rediscovering the nature of craft and its potential for contributing to design practice in conjunction with developments in science and technology. Through the analyses of craft and sustainability, strong connections are revealed as well as some incompatibilities. The contribution of this paper is to a) map a systemic view of craft and b) establish a theoretical understanding of the relationship between craft and a holistic understanding of sustainability. Drawing on recent research that proposes three areas of leverage for sustainability, we argue that craft, as a system of making, knowing and being, has significant potential to contribute actively and tangibly to the transitional conditions, thereby serving as an agency for sustainable transformation.

Keywords: Craft, Design for Sustainability, Leverage, Transformative Change, Human Values.

Understandings of design for sustainability have evolved from being primarily technology-based, to more holistic understandings in which broader understandings in relation to human values (Abson et al., 2016) are considered vital to bringing about transitional change. In this, traditional craft can offer important insights for positive transformation because it represents a communal and cultural knowledge, practices and values that are grounded in context and place. Moreover, craft can be understood as a way of thinking, as well as theory building through converting its often tacit knowledge into “formal” or explicit knowledge (e.g. Risatti, 2007; Sennett, 2008; Niedderer, 2014). Through an analysis of the nature of craft, and a holistic understanding of sustainability, the relationship between craft and sustainability is discussed in terms of accordances and tensions.

Craft: A Systemic View

Attempts to define ‘craft’ have given rise to a wide range of specialized literature (e.g. Lucie-Smith, 1981; Adamson, 2007, 2010; Risatti, 2007; Sennett, 2008; Niedderer, 2014, etc.). Among these writings, craft is considered the most elusive of concepts, which belongs to a “polythetic category” (Marchand and Ashgate, 2016, p.3, cited in Hyland, 2016), because it cannot be absolutely fixed in any particular definition. Here, we develop an understanding of craft from three perspectives – practical, epistemological and ontological.
Practical

Adamson (2010, p.3) poses an open-ended definition of craft that suggests it is “the application of skill and material-based knowledge to relatively small-scale production”. This gives room for a broad range of practices and is in accord with understandings that recognize craft in terms of embodied knowledge, materials, localism, small-scale, etc. (Shiner, 2012, p.239). This relationship between knowledge and craft’s tangible aspects is commonly discussed. Sennett says craft establishes “a realm of skill and knowledge perhaps beyond human verbal capacities to explain”. This know-how, skill or expertise is acquired over long periods of time by engaging in the slow pace of craft making practices (2008, p.295).

Through this process, specific kinds of knowledge are acquired and accumulate over time and, traditionally, were passed down from one generation to the next by an apprentice working alongside and learning from a skilled craftsman. This form of knowledge-sharing shaped the unique relationship between expert and pupil.

This kind of knowledge is developed in specific contexts (Brown, 2014, p.6), with locally specific materials and resources, and serving local human needs. Craftspeople root their practices in particular places, building on local traditions (Bop Consulting, 2012). This sense of place often represents an intensely personal or symbolic relationship with a locality (Racz, 2009; Williams et al., 1992, p.31) and is as unique to each locality as it is to each person. Hence, ‘local’ and ‘diversity’ are both important characteristics of craft practices. Today, however, due to digital communications, craftspeople can easily follow each other’s work and be connected across large geographical areas. This will undoubtedly affect the sense of the local in contemporary craft (Brown, 2014). Even so, as a response to globalization, mass-produced products and homogenized aesthetics, we are seeing a growing interest in local identity and products produced through craft practices.1

Craft is commonly considered to have low environmental impact. Often, environmentally-friendly processes and materials are used, and many traditional craft materials – like wood, wool and plant dyes – are renewable. Human energy is often a significant part of the process, along with small machines like lathes, sanders and electric saws. Also, craft objects often have long lifespans and their traditional designs – honed over generations – give them an appearance of timelessness (Ree, 1997 cited in Nugraha, 2012, p.106); this aesthetic quality is very different from the many short-lived, fashion-oriented, technology-dependent products made by mass-production. The ecological attributes of craft products are not just superficially embodied through the use of eco-friendly resources, recyclable material, etc., but are reflected in the culture of craft as a whole.

Epistemological

1 This could be exemplified by the Crafts Council in the UK supporting a series of craft projects since the 1990s, e.g. Tent London is an event dedicated to designers involved in craft practice (CraftsCouncil.com); in China, there are increasing numbers of collaboration between design schools, villages with traditional crafts and industrial companies to develop craft for contemporary use, e.g. New Channel project (App: New Channel), etc.
Some argue that craft reflects multiple ways of knowing which have the ability to engender complex thinking (Crawford, 2009, p. 23). The tacit knowledge inherent to craft practices is, as Polanyi (1961, ed. in L. Prusak, 1997) argues, a complex knowing process on which other types of knowledge (e.g. the cognitive) are based. However, Sennett (2008, p.50) points out that the self-awareness facet of reflection plays a part in the craft-making process, making judgements about tacit habits and reviewing assumptions. Hence, tacit knowledge and explicit awareness are interconnected in the craft-making process. Experience and practice are critical aspects in both acquisition and sharing of tacit knowledge (Lam, 2000) and craft quality emerges from their combined application. They exemplify two aspects of human intelligence: the experiential and the cognitive. Furthermore, some Knowledge Management (KM) scholars argue that these two aspects of craft ability, i.e. a craftsperson’s embedded or tacit knowledge, can be largely explicated and codified (Nonaka & Takeuchi, 1995, cited in Niedderer, 2011).

Again, Follett and Valentine (2010, p.5) refer to the thought processes used in craft making as a “system of thinking” that can serve as a strong agency to inform design (Woolley, 2011, p.31) and design organizations, especially with respect to interdisciplinary collaboration. They base this assertion on the idea that “the complex thinking engendered by craft knowledge could benefit knowledge exchange and shared understanding” across boundaries (Niedderer, 2011). Within the complex system of disciplinary collaboration, different areas of knowledge can be shared via “boundary objects”, employing ways of thinking inherent to the craft process (see Brown & Duguid, 1998, pp.103-104). In such collaborations and explorations, craft can provide an overarching guideline for the emerging interdisciplinary system, or it could serve as a boundary object to build common places.

As another way of knowing, some scholars introduce ‘spiritual intelligence’ as an unquantifiable parallel counterpart of rational (IQ) and emotional (EQ) intelligence (see Zohar, 2000; King, 2009). Spiritual intelligence refers to critical existential thinking, personal meaning production, transcendental awareness, and conscious state expansion (King & DeCicco 2009). Spiritual intelligence is a widely-appreciated wisdom in both religion and the sciences. Due to the challenge of codifying scientific criteria for spiritual intelligence, Gardner (2000) suggests using the term ‘existential intelligence’ instead of ‘spiritual’ to explore “the nature of existence in its multifarious guises”. However, he states that there is insufficient evidence about brain structure and neurological processes related to this form of intelligence. Existential thinking in craft is discussed further in the next section.

Ontological

**Authenticity**: Through the discussion of the practical and epistemological characteristics of craft above, a deeper issue emerges. The implications and meaning of the various aspects of craft and craft making could be encapsulated by the term authenticity. Apart from the originality in materiality and authorship, ‘authenticity’ describes “a person who acts in accordance with desires, motives, ideals or beliefs that are not only hers (as opposed to someone else's), but that also express who she really is” (Stanford Encyclopaedia of
Philosophy, 2014). Here, the term ‘authentic’ refers to that which is both physically real and philosophically true, but especially the latter, which is related to “moral-psychology, identity and responsibility” (Ibid). For physical realness, craft is traditionally produced from natural materials, human labour and ecological resources.

For philosophical trueness, craft making is a type of activity motivated by the desire to work well for its own sake (Sennett, 2008, pp.241-267); craftspeople find self-fulfilment in the freedom of experimentation (making) driven by an aspiration to pursue a high degree of excellence. In this process, craftspeople reflect critically on their goals and values, and are responsible for their own work. Taylor (1992) maintains that the “powerful moral ideal.... behind self-fulfilment is what a better or higher mode of life should be.... [offering] a standard that we ought to desire”. He further suggests that this moral ideal is something we wish for, but it is something that transcends us as individuals. This reveals aspects of deeper meaning in craft making, namely, existential (spiritual) meaning; this will be discussed below. In recent years, more and more people have criticized the inauthenticity of modern meaningless and purposeless work (e.g. Taylor, 1992, pp.2-4: Walker, 2011), instead celebrating the dignity of craft labour, which they argue, reflects a more authentic, ethical way of being.

Craft and existential (spiritual) meaning: Although there are disagreements about which term should be used in relation to scientific research, the most important point is that existential thinking is a significant human trait. It is related to human values but cannot be measured scientifically (Gardner, 2000).

From archaeological evidence, traditional crafts and practices are replete with value accumulation and the spiritual embodiment of ancestors. However, existentialists think these “activities and ideas” are produced from the acting, feeling, and living experience of human as individual rather than merely from mind or thinking (Macquarrie, 1972, pp.14-15). According to these ideas, material things are endowed with meanings that transcend the materials themselves through the making process; meanings can even pertain to the sacred or the divine. Risatti suggests that craft’s unique qualities come partly from “an ability to express human values that transcend temporal, spatial and social boundaries” (2007). These human values have been closely connected with the production of crafts and everyday objects for thousands of years (Ahmad, 2003 cited in Arshad et al., 2014).

In summary, craft is a field “established and defined through its perceived difference” (Adamson, 2010, p.5). However, its essence can be understood through several critical thematic words: ecological attribute, localism, complex thinking and authentic being.

Understandings of and Approaches to Sustainability in Design

The terms ‘sustainability’ and ‘sustainable development’ have been widely used over the past thirty years. Contributing to the understanding of sustainability are a series of ideas from the Triple Bottom Line to the Circular Economy that propose and demonstrate visions and
methodologies from their own particular perspectives. This deals with the common concerns of environmental integrity, social justice, and economic viability (e.g. Elkington, 1997; Ellen MacArthur Foundation, 2012).

In the design for sustainability field, numerous pathways have enabled solutions and initiatives to emerge over the past two decades. These include: Green Design, Cradle to Cradle, Biomimicry, Product/Service-based Systems, upcycling (McDonough & Braungart, 2013), Systemic Design (Ceschin & Gaziuulosoy, 2016), permaculture (Mallison, ed.1991, 1st ed.2013), social innovation (Manzini, 2014), and the recently-established Transition Design (Irwin, Tonkinwise and Kossoff, 2013). The practices and discourses of design for sustainability have yielded an unprecedented mix of ideas and approaches, but this has created some polarization. The discourse of sustainable design tends to be between technocentrism and ecocentrism (Orr, cited in Van der Ryn & Cowan, 2007, p.20; Luederitz et al., 2010); between the ecotopian and business-as-usual; between grassroots, bottom-up diverse models and centrally controlled, top-down paradigms (Manzini, 2014, p.57).

However, there is an emergent understanding and vision of sustainability, characterized by initiatives such as Transition Design (Irwin, 2015), and Agenda of Deep Leverage Points for Sustainability Transformation (Abson et al., 2016), both of which identify the need for a systemic shift in outlook and approaches. These resonate with the theory of holism (Kossoff, 2015) and systems view of life (Capra and Luisi, 2014), and share the common concepts of self-organization, interconnectedness, cosmopolitan localism and symbiosis. These conceptions resonate with the notions of deep leverage points for sustainability transformation (Abson et al., 2016). According to the old and the new (visions, concepts and ideas), the characteristics of design approaches in sustainability are identified as:

**Eco-effectiveness** is the core of the Circular Economy. The central principle of eco-effectiveness is ‘waste equals food.’ However, eco-effectiveness is mostly explored and discussed from technological perspectives of sustainability, such as Cradle to Cradle, Biomimicry and Systemic Design. It considers the flow of materials and energy from the waste of one system to the input of another, thereby creating a recyclable production chain (Ceschin, 2016). However, many scholars criticize it because it mainly focuses on technological and productive aspects, and fails to address issues from the personal and social aspects (Ibid).

**Cosmopolitan localization** emphasizes community-based local distributed systems, with the ability to share and exchange information and knowledge through ever-improving technologies and global network (Manzini 2014; Irwin, 2015, p229). This concept aims at first generating a resilient social mechanism and productive system to cope with the ever-deteriorating climate and social crises, while being coherent with another notion of sustainability – diversity.

**Self-production** corresponds to self-organization, which is strongly linked with autonomy (Massotte, 1995). Flexible, robust self-organization, development and production are
recognized as valuable factors to be imitated and used in system design for manufacturing (see Leitão, 2008). In recent decades, these concepts have inspired a movement towards self-production, which opposes Fordist mass-production and outsourcing, and which has been expanding since the 1990s in Europe (Ferrara, 2011, pp.5-13). In addition, this cultural trend encourages consumers to participate in the production process rather than simply purchasing the products off-the-shelf (Atakan, 2011). In the design field, self-production is based on co-creation that “represents the act of mediation between areas of knowledge” (Mazzarella and Engler, 2014).

Revision of lifestyle: lifestyle and everyday routines are fundamentally driven by needs and desires (Kossoff, 2015, p.31). Modern technology and modern design, operating within a market economy, continuously fuel people’s appetites. Constantly longing for improved products and new gadgets is not a matter of needs but of desires: this inevitably results in constant dissatisfaction. Modern lifestyles fueled, by constantly creating desires but failing to meet human essential needs which is criticized by Davies (2016), are “at the root of many wicked problems” (Irwin, 2015, p. 240). Therefore, modern lifestyle is in urgent revision in accordance with the principles of sustainability.

Relationship between Craft and Design for Sustainability

From the discussion and analysis above, it is not difficult to see how craft and sustainability connect with each other. The relationship between craft and sustainability can be understood in terms of accordances and tensions (see Table 1). The accordances – localism, eco-effectiveness, resilient system and lifestyle. However, because of craft’s roots in a pre-industrial age, there are also tensions – cosmopolitanism, productivity and economic viability. These three tensions result from our fast-paced modern technologies and economic demands. Cosmopolitanism and high productivity do benefit human civilization and progress, but criticism of these characteristics of modernity and technology is not new. Constantly pursuing productivity and profits without consideration of environmental and societal costs and systems thinking is widely condemned as creating a potentially catastrophic risk (Beck, 1992).

Craft as Leverage for Sustainability Transformation

Drawing on the concept of leverage points proposed by Meadows, recent research calls for three realms of deep leverage for sustainability transformation (Abson et al., 2016). These are:

- **reconnecting people with nature**: to what degree humanity relies on nature essentially influences the function of a system and human well-being; a disconnection from nature is identified at both individual and societal levels (Ibid, p.34);

- **restructuring institutions**: institutions guide and constrain action; institutional change represents a crucial realm of leverage for sustainability transformation; institutions include the formal - law, regulation and plans, and the informal – customs, taboos and codes of conduct (Ibid);

- **rethinking knowledge creation and use**: questions legitimate knowledge, and calls for new forms of knowledge production (Ibid, p.35).

Reconnecting people to nature

Craft can be regarded as a way of making ecological material culture based in a specific place. Craft practices tend to use natural materials and renewable resources in conjunction with human labour – a meaningful renewable energy. Use of natural materials in the course of human labour serves to connect people to nature, both through the making and the using processes. Craft maker and user foster a deep perception and awareness of natural resources and the environment. The localism feature of craft determines that craft production processes
occur in local communities, connecting people to specific cultures and traditions. In turn, this cultural connection further strengthens people’s relationship to the natural world and to place.

Restructure institutional culture

Craft represents an ecological and authentic way of seeing the world; one that has been overlooked for a long time. Abron et al. (2016, p.34) appeal to us to allow “otherwise inaccessible insights into the functioning of institutions”, and to improve institutional functioning in the face of multiple crises. The ecological awareness, cultural continuity and authentic lifestyle of craft and craft making could offer valuable insights for re-examining our current institutional culture and public ideology. People reflect on their current material culture by doing, using and appreciating craft. In the process, we foster changes in posture, mindset, and worldview, and thereby revise our moral norms, customs and codes of conduct. Eventually, these changes will affect and change our formal institutions of regulation and related policies.

Triggering new form of Knowledge

Craft can be understood not just as a way of tacit making but also as a form of complex thinking. Craft has been widely acknowledged as a type of informal and non-intellectual knowledge characterized by its non-verbality, incommunicability and being rooted in labour. However, this way of portraying craft is inadequate. Many craftspeople, artists and scholars regard craft knowledge as a combination of multiple ways of thinking. There are two key elements of craft that could contribute to the re-creation of new forms of thinking and knowledge. One is craft’s creative and subversive nature, the other is its ecological, ethical and authentic connotations that are grounded in local traditional culture. As evidenced by the Maker Movement, craft has informed many interdisciplinary collaborations and creative exchange. Also, practising a craft actually involves many elements: value judgements about materials and processes; moral norms that guide making and related choices; cultural and spiritual references to tradition and context.

Conclusions

Craft is viewed in this research through a philosophical lens as a comprehensive field capable of relating people to the natural world. Because of its ecological, authentic and existential meanings, craft has strong connections to sustainability. As such, it has great potential as a lever for change. For these reasons, craft is worthy of further research, especially in areas such as how it can be revalued and made it relevant to the present. In so doing, it will be able to make an important contribution to personal and social sustainability. However, there are also tensions between craft and sustainability in the contemporary context. How to mediate these incompatibilities is also crucial if change towards more sustainable ways of living is to be effective. Most importantly, the values inherent to craft, which are rooted in place and traditional culture, are potential domains for further sustainability research.

Abstract

Motion graphic design is a branch of information visual design. Based on questionnaires and the factor analysis of Statistics, this paper evaluated the hierarchy elements of motion graphic design through the cognitive performance of the three selected types of videos (from 9 selected sample). Furthermore, analysis of the design categories based on users' perspective; the weight ratio of each factor of design details in the cognitive process, and Set up visual data chart. The research is to provide a quantitative evaluation of motion graphic design methods and help to realize the value of cognitive analysis.

MG (motion graphic) is a comprehensive application of animation, graphic design, and information integration, a motion presentation of multiple senses which is a branch of information visual design (Krasner, 2013). It could help people receive various active visual information in a short time and a limited physical space, and it is also increasing the power of memory about this MG video. The design methods of MG is a combination of several media, including graphics, photo, text, animation, video, audio interpretation, etc. Richard Wallman, the Father of information structure, once said: "The goal of information design is to empower its users" (Wurman, 1989). The power comes from the quantity and quality of information. The designers can frame the means of broadcasting according to a specific target audience, make them obtain mass information from MG in a short time, and make the target audience interact with MG.

Analysis problems

MG design is a new type of information art design, though it has an animated expression form, it is a process of analysis and visual redesign of the whole information thinking, which needs to deeply understand the cognition and feeling of audiences when the designers start their designing. Therefore, it is essential to analyze the user's cognition performance. The "cognitive performance" here refers to the effect that the audiences receives objective information and subjective feeling from the design (Boff, Kaufman, & Thomas, 1986). It covers that a few individuals receive information and ability when enjoying videos, such as vision, attention, memory, thinking, intellectual activities, etc. At present, in the earlier stage of MG design, few studied in quantitative analysis for the survey of the cognitive feelings. Most of design from a subjective decision of designers.

Research methods

A quantitative analysis method was used in this research, and the data are from the questionnaires. MG design elements are divided into four major categories according to information conveyed, visual design, motion effect, sound, specified into 31 detail...
indexes, so that it is convenient for the tested crowd to choose and evaluate. The design and answering way will be introduced in depth in the following part. Participating in the study were 30 adults, all of whom were college students. When analyzing the data from questionnaires, factor analysis of Statistics was applied to complete the evaluation of cognitive performance. The factor analysis is to extract the primary or few influencing factors from several influencing factors to explain the effect on the results. Its main goal is to reduce variables and sum up them, and with this method, it is easier to figure out the characteristics of influencing factors. With this approach, MG design category based on users’ perspective can be obtained, as well as the weight ratio of each element of design details in the cognitive process.

**Research process**

**Video materials for the evaluation test**

Influential MG design works were selected as video materials, and empirical studies were carried on them. There was no stable model for MG design categories, so the video materials for evaluation was divided into three types: pure images, pictures & visual text, picture & Audio interpretation according to audiovisual elements. Such classification method based on element collocation and proportion, which might not result in ambiguity.

The first type: MG design in the expression of pure images. The central theme expressed by plane graphics, solid modeling, and physical images. There are few visual words or directive and illustrative statements and data drawing lists in the designs. They also have background music, while they do not have any oral narrations. Moreover, over 95% of the design is completed depending on images, graphic effects, and sound.

The second type: MG design in the combination of picture & visual words. The image content of this kind is mainly abstract images and solid modeling collocated with the key words. Visual words have motion effects, which play a significant role in the key guidance and inspiration for the readers. The Apple advertisement is a typical case in 2013, in which black-and-white abstract images collocated with the principal words were used to express the subject without any narrations.

The third type: MG design in the combination of picture & audio interpretation. This kind of design is expressed by visual animation collocated with audio description (narration). The scene is mainly expressed by vector graphics and data drawing list with narrative interpretation. This type of design is like expository writing which is concise, comprehensive, clear and easy to understand.

The description of the video material is shown in Figure 1:

Subjects investigated were divided into two categories: one is with design basis (short for the grounded group below), juniors majored in industrial design and had learned something in graphic and animation design. The other is without design basis (short for the ungrounded group below), who had little knowledge in MG and seldom got in touch with the design. 15 students were selected at random to answer the questionnaires. The tests were carried out for three times, and two of the tests were effective. 45 samples collected, and 30 of them were effective.

Weight questionnaires of MG design were used to investigate subjective perception and feelings of audiences on different design elements of vision, sound, motion effect when watching videos. Regarding vision, each element of MG was quantified in tables, and four one-class indexes, 13 two-class indexes, and 31 three-class indexes listed as perceptual cues. Evaluated in the values from 1 to 10 points. Through data, trend analysis of users' experience feeling and weight order of each perceptual elements can obtained. Firstly, the analysis of the relative elements of GM design divided the evaluation indexes into information, vision, motion effect, sound. Then, according to these key words, conclude and extract users' evaluation indexes in this experiment. To avoid doubts arisen from subjects on the questionnaires, interpretative statements added to the third index in the survey. (Figure 2)

Figure 2: Questionnaire information of MG design elements weight

**Answering questionnaires**

In the investigation, we extracted 30 students to carry out batch tests, 15 persons each time, and each test lasted for two hours. In each test, questionnaires were first given to subjects, and they had about 3-5 minutes for scanning. Then nine videos were played in the order of clear images, pictures & visual words, picture & audio interpretation. Each type had three videos in different styles. Subjects were not told the video category when playing.
them, which can reduce the interference of subjective information of designers to the subjects and make preparation for the research on design group in perspective of users.

The average length of videos is 2-3 minutes, and the longest one is about 9 minutes. Each video would play for three times. In the first time, subjects scanned it and made a preliminary impression in his mind; in the second time, the video would evaluate. Subjects could grade it depending on subjective impression; in the third time, unimpressive or uncertain information of the video would be implemented, and the grade would be perfected. During the test, subjects had finished grading basically in the second time. Through observation in the site, audiences were more interested in short videos, especially videos in 3 minutes. For those over 5 minutes, audiences might begin to show fatigue in various degrees, from which we can infer that the length of MG design is one of the factors influencing users' experience. Therefore, if a high expression is needed, segmented video or series design can be adopted.

Data analysis

The cognitive performance here refers to the effect of subjective information and objective feelings obtained by individuals in appreciating motion graphic design. It is divided into two parts; one is based on the comparison of MG design in users' perspective; the other one is the users' analysis of element thinking of design details in the cognition.

Analysis of MG design category based on users' perspective

Design category from users' perspective can be obtained by factor analysis, which has an auxiliary effect on understanding users' visual feeling. Decide which quantity factor should be selected: according to the explanation of initial eigenvalue in the total variance table, estimate the factor quantity to be chosen, the number of those with >1 eigenvalue was the category quantity to be chosen. In the evaluation of grounded group, the number of those with >1 eigenvalue was 5. Therefore, five types should be chosen (Figure 3). In the evaluation of ungrounded group, the number of those with >1 eigenvalue was 6. Therefore, six types should be chosen (Figure 4). Also, the percentages accumulated by the first few factors in initial eigenvalue were 94.57% and 96.67%, which means these factors can be used to explain samples at 94.57% and 96.67%. In general, the larger the value is, the more representative and critical the chosen factors are.

Confirm the variables of each factor: according to the component matrix above, confirm variables of each factor and choose variables with large coefficient in each type. In this statistic, 0.5 was set as a standard to choose variables (often choose variables over 0.4, but sometimes a larger variable can be chosen according to the actual situation). In the evaluation of grounded group, design elements larger than 0.5 among the five factors were 21, 13, 14, 3, 2. The fourth and fifth factor were eliminated for there were few design elements in them, so there were three results of the elements orders of all the effective factors. In the evaluation table of the ungrounded group, design elements larger than 0.5 among the six factors were 29, 9, 2, 2, 2, 0. Therefore, the same as the grounded group, for there were few design elements in three to six elements, which did not match the induction conditions, three to six elements were eliminated.

According to effective factor variables, the statistic result showed: the cognition
category of the ungrounded group was divided into two: pure images and picture & visual words were combined into one type, which can be regarded as MG design in images and in audio interpretation. The cognition of the grounded group was the same as the three types pre-installed. Pictures collocated with visual words and pure images were regarded as images by the ungrounded group, while the grounded group have a better understanding and show more interests in images than the ungrounded group. The ungrounded group were more accustomed to learning through narrative interpretation. (Figure 5, 6)

![Figure 5: The evaluation values of each element from ungrounded group](image)

![Figure 6: The evaluation values of each element from grounded group](image)

**Weight analysis of design elements in cognition**

Through factor analysis, results can be found the grounded group and the ungrounded group had different ideas on MG design cognition category. Further, obtain the weight value of the three-class index in 3.1 and weight sum of one-class in 4 for the research on the element order of influencing users' experience. The larger the value and the higher the ranking of elements are, the more attractive they are to users, and users are satisfied with the design details. There is no definite ranking of elements, and statistics also showed that many elements were at a similar value. Sequencing them was only used for marking element level and assisting designers to consider the design.
The second type: picture & audio interpretation. Elements of this type with design value over 0.5 ranking in top 10 were: the colors of music, comprehensibility, information accuracy, the easiness to understand information, font, color and light, speaking speed, position, scene cohesion, resonance. Vision convey weight sum was 7.31; information conveys weight amount was 4.303; motion effect weight sum was 1.965; sound design weight sum was 0.777. This type mainly focuses on audio interpretation, so there was a small proportion of vision. There were narrative descriptions, and information can be accepted quickly, so there were four elements about information understanding among the top ten elements, which means it was easy for users to understand the information, and there were little doubts. Therefore, narrative

Figure 7: Weight analysis on MG design element from grounded group

Result analysis: the first type: pure images. Elements of this kind with design value over 0.5 ranking in top 10 were: the fitness of music and subject, mode of exercise, harmony between music and graphic motion, frequency, lens rhythm, abstract images, music rhythm, figure base proportion, aesthetic and design techniques. The vision weight sum was 12.089, followed by the motion weight amount 4.791. Because camera movement and transitions of graphics are important design factors of matching images. Then the sound weight sum was 2.732, and the information conveys weight amount was 2.694. Users need to have a good understanding of figures and pictures towards this kind of design, but many users did not understand the intention of these design works, so the value of information convey ranked the fourth.
interpretations played a major role in promoting the users' recognition and resonance, but regarding statistics, the attention of the users on figure design and motion effect transition design would be reduced for a little.

The third type: pictures & visual words. Vision convey weight sum was 6.766; information conveys weight amount was 1.644; motion effect weight sum was 1.555; sound design weight sum was 0.228. In this type, there were only eight design elements whose value was over 0.5: size of words, position, length, color number, fonts, concrete figures, overall effect. Among them, there were three elements about words and four about figures and images, which means when words are added as visual elements into design, creative design of words should be focused on. Therefore, it is the key to this type of design to collocate images and words with visual effects.

Figure 8: Weight value analysis of each MG design elements from ungrounded group

Results: the first type: picture & audio interpretation. Design elements with over 0.5 value ranking in top ten were: special effects, resonance, effectiveness, information accuracy, lens movement, the overall effect, the coordination of music and graphics.
movement, pictures, word size, fitness between music and theme. Visual convey weight sum was 10.89; information convey amount was 5.656; motion effect weight sum was 3.994; sound weight sum was 2.319.

The second type: pure images and picture & visual words. Design elements with over 0.5 value ranking in top ten were: font, mode of exercise, sound rhythm, space effect, abstract figure, concrete figure, font position, frequency, the proportion of image base, font color. The convey weight sum was 6.182; motion effect weight amount was 1.682; information conveys weight sum was 1.509; sound weight sum was 1.536.

The results showed that the values of resonance, effectiveness, and data accuracy were high in MG design with narrations, which means users accepted this type very much; there were few doubts in answering questionnaires; users made an excellent oral evaluation of it. Therefore, if narrations are adopted in the design, figure creation can be simplified. The second type designs and design & visual words were analyzed through users’ perspective. From the top ten elements, a conclusion can be drawn that sound, motion effect and, color collocation are needed for picture and image design. Only when a complete visual system is formed can the design intention be expressed. Therefore, this kind of music and graphics transitions are also the key to design.

According to the weighted sum obtained above, adopt a pie chart to express the four one-class index proportion of the two groups of users, which can present the ratio of different kinds of MG design elements more clearly. (Figure 9, 10, 11, 12, 13)

![Figure 9: weight analysis of each element experience from ungrounded group: picture & audio interpretation](image-url)
Figure 10: Weight analysis of each element experience from ungrounded group: picture, picture & visual words.

Figure 11: Weight analysis of each element experience from grounded group: picture.
Result and discussion

MG design is one of information visual design. Visual design elements have many detail elements in the 31 three-indexes, which takes the largest proportion in the experienced weight of the two groups. Therefore, figures and images always play an important role in the expression of design intention. The information conveys effectiveness of the picture & visual words type of grounded group increased to 18%, and sound and motion effect took a total account of 6%, which means the creative design of keywords had an evident effect on the scene understanding and attention of
users. The information conveys ratios of the two groups in picture & audio interpretation were 30% and 25%, which means both of the two groups had excellent information accuracy and resonance and could easily understand the problems explained in the video. This type of design is simple and easy to be understood, but the visual feeling will be reduced. Therefore, it would be the best to adopt concrete modeling to express the subject. If the design is intended to apply abstract figures to make users produce associations or be attractive by the visual impact of the scene, it would be the best to design with pure images and few visual words collocated with images. The type with the highest sound ratio of the two groups was pure images with 16% of the grounded group and 14% of the ungrounded group, which means the type of pure images has the highest requirements on sound design, and users will apprehend problems in a combination of watching and listening.

Conclusion

The main limitation of this study there were not so many subjects, and these subjects share a similar background. In the later tests, the number of subjects with different background can be increased. MG design is not only a single visual convey or animated design anymore, but is user-centered and focuses on information visual design of users' experience. In the early stage of design, motion graphic designer needs quantitative analysis to reorganize information, explore its value and comprehend the real intention of users. Constantly further researches on quantification analyses and test methods are needed in this field. Statistics analysis of this project was based on the data from questionnaires, and the data also provided significant information for design.

Empowering the Preschool Children: A Service Platform Design Aiming at the Communication of Balanced Diet Information
Xing Zhou, Tongji University, Shanghai, China, zhoux@tongji.edu.cn

Abstract

Childhood obesity increases the risk of obesity in adulthood and is associated with cardiovascular disease risk factors. The prevalence of overweight and obesity is increasing in China. It is necessary to develop an intervention project for preschool children. Based on a service design project aiming at the communication of balanced diet information to the preschool children in China, this paper discusses how to take advantage of the digital platform and game-based learning to empower the preschool children. It argues for the importance of the DIKW hierarchy for empowerment. It also proposes an innovative model to involve new stakeholders into the whole system and to improve the viability of the project.

Keywords: Service Design; Obesity; Game-based Learning; Healthcare; DIKW Hierarchy; Preschool Children.

As the world’s most populous country and the largest developing country, China has a large population that accounts for one-fifth of the global population. With impressive economic developments over the past three decades, Chinese people have experienced many dramatic changes in lifestyles, which are often associated with an increase in obesity and chronic disease. This paper discusses a service design project proposed to tackle this healthcare problem in China.

Background

The Prevalence of Obesity in China

With impressive economic developments over the past three decades, the lifestyles of Chinese people change dramatically thanks to an increase in family income and an increasing availability of food owing to advances in agriculture and increased global trade. Wang, Mi, Shan, Wang and Ge (2007) studied the nationally representative data between 1992 and 2002, and found that the prevalence of overweight and obesity increased in all gender and age groups and in all geographic area. Using the World Health Organization body mass index cut points, the combined prevalence of overweight and obesity increased from 14.6 to 21.8%. The Chinese obesity standard shows an increase from 20.0 to 29.9%. Wang et al. (2007) also found that with the increase in overweight and obesity, obesity-, and diet-related chronic diseases also increased over the past decade and became a more important preventable cause of death.
Besides the overall data, some scholars focused on childhood obesity. Dietz (1998) found that childhood weight affects adult morbidity and mortality. According to his study, approximately 50% of obese adolescents with a body mass index at or above the 95th percentile become obese adults. Furthermore, the risk factors for adult disease that are associated with obesity in children and adolescents persist into adulthood or increase in prevalence if weight gain occurs. Chu, Rimm, Wang, Liou, and Shieh (1998) evaluated the clustering of cardiovascular disease (CVD) risk factors among obese schoolchildren in Taiwan, and confirmed that childhood obesity increases the risk of obesity in adulthood and is associated with cardiovascular disease (CVD) risk factors such as hypertension, diabetes mellitus, and dyslipidemia. He, Ding, Fong, and Karlberg (2000) identified the risk factors of obesity in preschool children in China, and suggested children between 3 and 8y of age should be considered as the target group for nutrition/obesity intervention programs. It is necessary to develop an intervention project for preschool children.

The Emerging Generations of Digital Natives

Thanks to the development of the information technology, those who were all born after 1980 all have access to networked digital technologies. Being called as “digital natives”, they never experienced an analog-only world. They didn’t have to relearn anything to live lives of digital immersion. They learned in digital the first time around (Palfrey and Gasser, 2013). The emerging generations of digital natives are familiar with smart phones, tablet PCs and the Internet. Their lives rely so much on the information technology. When the first generation of digital natives becomes parent, they are willing to take advantage of the information technology in their kids’ lives, which also gives their kids more exposure to the digital world. Many kids are enjoying all kinds of applications on their smart phones or tablet PCs. Some of them even become addicted to the digital world, which is drawing more and more concerns from their parents and the society. While people appreciate the magic power of the digital world supported by the information technology, they are becoming more and more concerned with the fact that many children are detached from the physical world. To conclude, it is very powerful to take advantage of the digital platforms to develop an intervention project, but the negative effect of the digital platform should also be reduced.

Literature Review

Design for Healthcare

As the most hands-on of professions and services, healthcare is developing rapidly with the increasing complexity. Design used to make contributions to the creation of the artifacts in healthcare sectors, and now is emerging as a critical role in all types of healthcare services. Jones (2013) believes that healthcare technically entails many wicked problems. Healthcare is a massively complex system that deals with at least two irreducible sources of complexity: the institutional and the personal. Design is challenged to help clinicians and patients navigate complex situations within healthcare systems. Roberts, Fisher, Trowbridge, and Bent (2016) discussed how design thinking can foster new approaches to complex and persistent healthcare
problems through human-centered research, collective and diverse teamwork and rapid prototyping.

Empowerment in Health Promotion Interventions

Thanks to the Alma Ata Declaration (WHO, 1978) and the Ottawa Charter for Health Promotion (WHO, 1986) published by the World Health Organization, the concept of empowerment has been used frequently in the field of health promotion. In the literature, empowerment can be viewed as a process, or an outcome. Zimmerman (1995) distinguished empowering processes from empowered outcomes. Empowered outcomes are one consequence of empowering processes. As an outcome or goal, empowerment concerns the individual’s (or group’s) control over his (their) life. As a process or means, empowerment is about letting the client, group or community have as much control as possible over the change process they are involved in (Tengland, 2008), including goal/problem formulation, decision-making and acting. Many health promotion programs have implemented the empowerment approach. Researches on the evaluation of the empowerment have increased.

Data-Information-Knowledge-Wisdom Hierarchy

Jones (2013) proposed four levels of Clinical Design: from 1.0 to 4.0. He argued that a design process should match the level and variety of a context to accommodate its complexity. He analyzed the context of care information which follows the Data-Information-Knowledge-Wisdom hierarchy (Figure 1). The DIKW hierarchy is one of the fundamental, widely recognized models in the information and knowledge literatures. It is believed that the first appearance of the hierarchy was in T. S. Eliot’s poem The Rock in 1934. Ackoff (1989) developed the DIKW schema for management applications. He proposed a hierarchy with five levels: data, information, knowledge, understanding and wisdom. In Ackoff’s hierarchy, understanding was included, but more recent commentators have disputed that understanding is a separate level. The DIKW hierarchy has been extended to knowledge management and, more recently, design research analysis.
In this project, desk research, observation and interview were carried out to collect the domain knowledge, discover the design challenge, and gain insights on the users and other stakeholders.

**Desk Research**

In this step, we collected the related information. All the related information could be classified into three groups. The first group is the literatures about the obesity problem in China. From the literatures, it is obvious to observe the prevalence of obesity in China. Some scholars have done some studies on children obesity. It is confirmed that childhood obesity increases the risk of obesity in adulthood and is associated with cardiovascular disease risk factors. It is necessary to develop an intervention project for preschool children. The second group is the literatures related to the healthy diet. Appointed by Ministry of Health of China, Chinese Nutrition Society published the Chinese Dietary Guidelines and created the Chinese Dietary Balance Pagoda to better deliver the concept of balanced diet. However, it is still difficult for children to learn such information from a thick book. The third group is all the information about some intervention programs. For example, the Fitwits program designed by Carnegie Mellon University also focused on the obesity problem. It included participatory workshops and tools aiming at helping physicians start conversations with families about obesity.

**Observation**

To understand how the preschool children interact with different digital products, five on-site observations were carried out. We recruited five families with preschool children in Beijing and
did a home visit to each family. A two-hour on-site observation was carried out in each family. According to the observations, we found that preschool children in these families were quite familiar with different digital products including smart phones, tablet PCs and TVs. They played digital games, listened to the music and watched cartoons on these digital products. They had no difficulties in interacting with different digital product. (Figure 2).

Figure 2: A three-year-old kid interacts with different digital products (Family A)

Interview

During on-site observation, we also interviewed the parents of the five families. A semi-structured interview was carried out in each family. Through interviews, we aimed at learning about their lifestyles, attitudes and concerns, which helped us formulate our insights. According to the interviews, these young parents were willing to take advantage of the digital products. They cared about the health of their children and tried to help them form good habits. They concerned about the food safety and some families turned to organic food after their children were born. They also had concerns on the addiction to the digital products. They tried to help their children balance between indoor and outdoor activities.

Design Implementation

We concluded all the insights we got from the research, and converted insights to design principles, reframed assumptions.

Framing Concept Space

The concept is aiming at the communication of healthy diet information to preschool children. Digital products could be used as the communication platform. For preschool children, game-based learning is a suitable way for communication. While taking advantage of digital
products, the negative effect of the digital platform should also be reduced. To be sustainable, the viability of this project should also be considered.

Overall Concept

Through discussion and analysis, we decided to develop a digital service platform based on iPad. The name of the App is Foodie Kids. (Figure 3) The App has three modules. The first module is a game aiming at introducing different food such as vegetables and fruits to the kids. The second module is a game aiming at delivering the concept of balanced diet. The third module is a service platform including three different parts, which includes new stakeholders into the system to provide offline services and increase the viability of the project.

![Figure 3: The Icon of Foodie Kids](image)

The First Module of the Concept

The first module of the concept is a game aiming at introducing different food such as vegetables and fruits to the kids. By interactive communication, it tells the kids where the food comes from and how the whole growth cycle is. For example, kids can learn how the tomatoes grow from seeds to fruit. (Figure 4) By doing so, it can introduce the whole growth cycle to the kids and improve the understanding of the specific vegetable.
The Second Module of the Concept

The second module is a game aiming at delivering the concept of balanced diet. In this module, we convert the Chinese Dietary Balance Pagoda into a game, which let the kids select different food and make a balanced meal by themselves. (Figure 5) By trial and error, kids will finally get
the concept of balanced diet. Compared to the original Chinese Dietary Balance Pagoda, game-based learning let the children adventure by themselves and finally learn such a complicated concept by playing interesting games.

Figure 5: The Second Module of the Concept
The third Module of the Concept

The third module is a service platform including three different parts. (Figure 6) The first part involves the organic farms into the system. It provides the organic farms a new platform to offer potential customers farming experience. Through this platform, on one hand families with children can have access to different farming activity provided by organic farm nearby, on the other hand the organic farms can connect to their potential customers. The second part is an e-commerce platform focusing on board games. Board games similar to the online games can be designed and sold through the platform. With similar board games as the digital ones, children can still be connected with our system while they are away from the digital products, which will also relieve the concerns of the parents. The third part is named as Little Urban Farmer, which is an urban farming promotion platform. It provides information on urban farming and sells toolkits. It will offer the children in the city valuable farming experience. All the three part in this module include new stakeholders into the system to provide offline services and increase the viability of the project.

Discussion

Integrating Online-to-Offline Services by Digital Platform
In this project, we designed a digital solution to intervene the obesity problem in China. However, the digital solution doesn’t only serve as an online service. It also acts as a platform to integrate the online services with the offline ones. With this platform, customers can have a whole integrated experience. The digital platform provides the potential customers a new touchpoint to the offline services. It is very useful for traditional industries to provide a new digital touchpoint to their customers, and it may also bring in new customers.

**DIKW-Hierarchy-Embedded Software Architecture**

To empower people, the DIKW hierarchy should be embedded in the whole logic. The software architecture of this project follows the DIKW hierarchy. The first module introduces different food to preschool children, which provides them with sufficient data and information about the food. The second module delivers the concept of balanced diet, which includes knowledge about how to select and make a balanced meal. The third module provides preschool children with multiple options to form their own wisdom. By building connections between their personal lives and the community, it helps them to shape their own value systems. With DIKW-hierarchy embedded, the whole service becomes more logic.

**The Benefits of Game-based Learning**

To communicate complicated concepts to preschool children, game-based learning is very useful. In this project, we convert the Chinese Dietary Balance Pagoda into a game, which allow children to learn by playing. By trial and error, kids will finally get the concept of balanced diet. Besides, some research has found evidence for improvement in cognitive processes through game-based learning. For example, Green and Bavelier (2003) compared the visual abilities of those who played action games to non-players by conducting five experiments. Improvements were found in different indices of visual attention for the players.

**Conclusion**

This paper makes three contributions. First, we proposed an intervention project aiming at the obesity problem in China. With a digital platform as a new touchpoint, online and offline services are integrated into a unified whole. Second, this paper argues in order to empower, the DIKW hierarchy should be carefully considered. A theory-embedded service will be both logic and meaningful. Finally, this paper exemplifies how game-based learning could be utilized while communicating complicated concepts to preschool children.

Development of a Design Competence Model for Learners of Human-Centered Design

Christi Zuber, PhDc, RN  Aspen Labs LLC and Coventry University

Abstract

Learning a new competence and attempting to perform it within an organization not only takes time, but it is heavily influenced by the real-world context of day-to-day work culture and individual perceptions. The little-understood world of learning Human-Centered Design (HCD) within an organization is studied over one year in inside of a group of healthcare organizations through a training and mentoring program called the "Innovation Catalyst Program."

Deep insights and personal narratives are gathered by studying learners and their coaches in real-time observations and conversations. A dynamic story unfolds as those who are learning creative approaches for organizational innovation are coached by those with many years of experience on the topic. These same participants provide feedback on the frameworks generated.

The result of this Longitudinal Grounded Theory field study is a new actionable model for understanding experiences and approaches to learning HCD within the context of an organization, a novel approach to assessing development, and ultimately, a way to empower individuals with the mindsets and skillsets of HCD for real-world challenges.

Keywords: human-centered design, capability development, innovation, design thinking, healthcare, Design Competence

Literature Review

Research has focused on how design thinking, or Human-Centered Design, can build innovation capability in an organization (Carlgren, 2014), but little has focused on the capabilities and experiences from an individual learner’s perspective within an organizational setting (Seidel and Fixson, 2014). Studies of students have explored how novice multi-disciplinary teams learn and successfully practice HCD in an academic setting (Seidel and Fixson, 2014) and how experts practice design in consulting settings (Haragon 2012) but studying this phenomenon of novice HCD learners in organizational settings, particularly within healthcare, is a gap in the literature. It is argued that it is of value to explore that through a longitudinal study approach to follow the development of this phenomenon over time.

The developmental nature of a longitudinal study was deemed to be the best fit for examining that learning journey, as it is a phenomenon that takes time to observe (Pettigrew, 1990). Application of longitudinal study approach in this context is relatively rare, with an example emerging very recently (Amabile and Pratt, 2016). The researchers adopted an online diary study to expose the day-to-day experiences of individuals working inside of organizations to
apply their creativity toward organizational innovation. This study of individuals learning HCD for creativity and innovation builds further on the researcher’s work to demonstrate the context of the occurrences and change in events over time (Lincoln and Guba, 1985; Ponterotto, 2006; Cresswell and Miller, 2000; Greetz, 1994).

The aim of this research is to identify and begin to codify the enabling conditions for individuals to learn and apply HCD within an organization that are not commonplace in design (Seidel and Fixson, 2014; Amabile and Pratt, 2016). Those approaches and conditions will be further considered through the application of frameworks created in the author's prior research. The desired outcome is to provide a repeatable process and practice-based framework for others who strive to bring HCD into their organization and for the organizational leaders who wish to support its use.

Research Methods

The study was designed around the Center for Care Innovation program called the “Innovation Catalyst Program”. This provided a unique opportunity to study a group of learners and coaches during their journey on the program within this large healthcare organization. This research study is not an evaluation of the Innovation Catalyst Program, but is focused on the experiences of the individuals, both learners and coaches, who are a part of the program.

The Innovation Catalyst Program

The Innovation Catalyst Program, hereafter called the “Program” or the “Catalyst Program,” began in 2014 and was in the third year of operation during the time of the study. At the time of the study the program was run jointly by Kaiser Permanente, a not-for-profit healthplan, and the Center for Care Innovations, a grant-making and collaborative network of providers specifically serving economically disadvantaged populations. The Catalyst Program is described as “a network of local innovation champions trained to use human-centered design and design thinking to add value to existing projects and initiatives in health care organizations” (www.wearecatalysts.org/about). The primary components of the Program are described as skill development, principles and methods, online learning community, coaching support and events and workshops (per the CCI Catalyst website).

The Program was selected as the focus of the study because it is regarded as an exemplary internal capability program within the design field as judged by the Design Management Institute (DMI website: www.dmi.org/?whatisdm) and an international group of experts. As such, judgement sampling was used to select the program, as it is in line with the philosophy of this research and enables a focus on learning from experts and exploration of what is working and how.

The participants – learners and coaches

The learners were required to apply for the program. Their selection included the prerequisite that they had the support of their direct manager to spend 20% of their time toward the program over the 12 months of the program. It was also requested that the learners apply in conjunction with 1-2 other individuals they worked with regularly, and finally that they have an existing
project effort toward which they could apply their learnings. Applicants to the Catalyst Program were chosen by the program administrators of the Center for Care Innovation and Kaiser Permanente. In total there were 48 learners in the program for the calendar-year study, and each team was provided a coach who was considered an expert in the methods of design. All participants in the Catalyst Program, both learners and coaches, were approached to consider joining this research study for the 12-month learning journey, and all provided their consent.

Per the program website, (http://www.careinnovations.org/programs-grants/catalyst), the selected applicants were provided with learning opportunities, learning materials, a coach, and educational materials to help them to build their innovation capabilities through the use of “human-centered design methods and mindsets.” The goals stated were to help “drive different ways of working in their organizations” by aiding each of them to become an “innovator” and “change agent” through the use of human-centered design within their organization.

“They [the coaches] taught us that there is a teachable, learnable skillset for innovation, but also a level of skill and expertise that we can all aspire to.” – George Su, MD, Associate Professor of Medicine, San Francisco General Hospital, in an Innovation Catalyst video interview

| Table 1: Participating Organizations |

Planned Parenthood of San Bernadino County 2
San Diego La Maestra Family Clinic 2
Central City Concern Clinic 2

The participating organizations represented healthcare community-based organizations serving a range of demographic groups. Each Innovation Catalyst participant was employed by one of these organizations.

**Research Methods**

A grounded study approach (Glaser, 1992; Strauss, A. and Corbin, J., 1994) was used for this longitudinal study. The research study then tracked the coaches and the Catalyst learners over a 12-month period, as was deemed the best approach to observe changes in the learner over time (Lincoln and Guba, 1985; Ponterotto, 2006; Cresswell and Miller, 2000; Greetz, 1994). During the study, the data was collected through a variety of sources to allow for better triangulation and to minimize researcher bias (Cresswell and Miller, 2000). The data collection included observations, ethnography, artefact analysis and user input and analyzed using Thematic Analysis (Braun and Clarke, 2006). An overview of how the data were collected over the 12-month period is given below in Table 2.

</table>
There were a variety of artefacts that were reviewed. A printed book, called the “Innovators Guidebook,” which contained the methods, context, and rationale, was provided to the learners at the first Kick-Off session. Method cards were also provided, which served as a quick reference summary deck of the guidebook. Each card contained information on one method, and the cards were bound together with a ring, allowing the cards to be removed or re-sorted at will.

And lastly, a website was available containing the same information on the design methods for innovation, the mindsets that were taught during the kick-off meeting and additional context for the learner. The website had a posting functionality that allowed the learners and coaches to have discussions together and post tools and documents to share amongst the cohort.

Discussion

In the following sections the experiential data collected are reported and explained. Fifteen different frameworks were presented back to the learners and the coaches, as well as to academics and thought leaders in human-centered design. The purpose was to gather their feedback on what ideas they felt would be useful in their practice, what ideas seemed to reflect and provide structure to what they had experienced, and how to make the frameworks better. Their feedback was incorporated into the final models provided; one developing model, the focus of this research paper, revealed competency stages in learning HCD.

Insights into the learner’s journey

The analysis sought to identify experiences and enablers of the learner’s journey as it applies to learners' perceived and observed experiences over time. The assessment begins to fill in the gap between the new learners (Catalysts) and those of experts (the coaches), who have had many years of experience. The desired result is to develop tools and models to better enable new HCD learners and teachers.

Organizational culture as context

Despite an affinity for people and the work, approximately 30% of the Catalysts expressed experiencing challenges with their work colleagues' morale, as well as incurring “unhealthy” cultural challenges. They believed that these led to a lack of desire to engage in the work and a resistance to change. The Catalysts struggled with knowing how to both learn and practice the methods, as well as navigate cultural challenges within their organization at the same time. For some, it caused their project work and their ability to practice the methods to stall for a period of a few months.
“We did a journey map of process, we had staff going out to capture perspectives and posting ideas and notes during clinic real time onto idea boards. We did clustering during staff meeting real time and idea boards in clinic. What we discovered is that we need help with culture issues because idea boards revealed bad culture issues based on what was posted. It shocked us actually. We’ve been stuck in this place for a while now.” – Catalyst learner, Improvement Consultant

Other Catalysts discovered that the methods themselves could help address some of the cultural issues they were facing. The first statement captures the methods they used to bring people together and the second was a reflective moment one of the Catalysts had about why it was so important for users to be involved and how it was different from how she’d worked in the past.

“We needed help to shift the culture of the clinic. We’ve been using lots of brainstorming, process mapping and journey mapping. Doing this has helped to address issues because we are doing it in face-to-face joint sessions. People weren’t wondering what we were doing anymore because they were a part of it.”

-Catalyst learner, Clinic Manager

"Just having a meeting where you get a few people like the users and other clinicians to actually look at it and reflect on it just does so much for morale. We've all been on the receiving end of things that are just missing the mark and not what we need. ...now what I realize is that I need to hear from people. They may tell me about what can work and, yes, we might get a whole other slew of ideas and sometimes that’s hard to take. But you will definitely end up getting support for the work. I think a key goal of all this work is to get people to contribute to their own system in a different way, and that alone will be so amazingly useful.” – Catalyst learner, Consultant

Right sizing the learning approach

Being given a high priority and highly visible challenge to work on was common for the Catalyst learners. Coaches spent significant time trying to re-scope and break the project into smaller components. They struggled with which was more important for the Catalysts, addressing the challenge or learning the skills. The coaches discussed at length the wish that Catalysts would join the program with a smaller and “less visible” organizational project that they could use to learn and try to apply the HCD skills toward.

“I took it to heart when you gave me the advice at Kick-Off that the people who are most successful apply this in many areas of life, not just their innovation project. I tried it with my kids first. We brainstormed about our vacation. It was clunky but they were totally into it. Later that month I ran a brainstorm at my team meeting and I felt better about it by then. It was good to have one under my belt at home for sure.” –Innovation Catalyst learner talking to their Coach
“If we were to look at some of those teams who are really struggling and we were to see that they need to really understand, look at what holds people back from change and what it really means to be a change agent. You know, sort of that cultural context. That may be more of what some of those teams need than knowing how to design things and run out to try to get people to try them. Because they don’t even understand the context and the culture. So they are trying to be doers, but they are getting stuck in the bigger contextual issues. And they can’t practice the methods enough to learn that design can actually help with those cultural and contextual things. They are stuck in the complicated effort when what they need are small scale ways to learn and practice right now.” - Catalyst Coach

Change in learners over time

The learners began the study struggling to find “safe” places to apply the new tools they had learned in the Innovation Catalyst training program. They sought after their coaches’ advice frequently over situations where they felt “stuck,” believed they could not practice what they had learned because they needed help to engage stakeholders, or couldn’t figure out where to begin on a project that felt “too big” or “too complicated. The coaches would find small ways begin learning and practicing. They would tell the Catalysts that the important element was to apply and practice their newly learned skills as soon and as frequently as they could. The coaches would help guide them on how to do that. By the time the Catalysts attended their In-Person Innovation Fair five months into the program, about half of the participants expressed that they had become more comfortable with the methods through practice and were now beginning to combine the HCD approaches with other methods they had learned during their careers.

“I got in front of some of our leaders and physicians at a meeting and I asked them to draw their experience. They didn’t do it. And I realized that I didn’t have anything in my bag of tricks after that. I was stuck.” – Catalyst learner at 1 month

I’m feeling a lot better about my own skills now. The other day I took what I’d learned (in a different program) about how and why people resist change, and it made me look at field testing my prototypes differently. Then it wasn’t just about the idea, but the chance for people to experience it and have an opinion that was heard. I could weave those things together as I spoke with them and it gave me a whole new approach. I was like, light bulb!” – Catalyst learner at 5 months

The ideas presented below went through a series of iterations from user feedback sessions. The final results of the sessions are provided.

First round of feedback

The experiences such as those demonstrated above were translated into insight and then into 15 different draft paper models. They were provided to coaches and Catalysts in a series of co-design sessions. One model that received strong interest was the idea
of breaking down the learning experience into different stages. The first prototype and a few comments from one of the sessions can be seen below.

The ideas presented below went through a series of iterations from user feedback sessions. The final results of the sessions are provided.

Leveraging existing learning models

An emerging model of the learner and the stages they go through has begun to develop. When the user feedback data was all reviewed in total further research was conducted as is common in a Grounded Theory approach. The Dreyfus “Five Stage Model of Adult Skill Acquisition” (Dreyfus, 2003) was selected due to its active stages of learning from novice to expert, or as Dreyfus calls it, mastery. The experiences are synthesized into the five development stages to demonstrate a change over time.

Upon further research, it was discovered that this model was later reviewed by Benner, a researcher and nurse who found parallels between this model and nursing. She theorized that improved practice depended on experience and science, and that skill development was a long developmental process (website: http://www.nursing-theory.org/theories-and-models/from-novice-to-expert.php). In Benner’s Novice to Expert model (Brenner, 2003), as in the Dreyfus Skill Building Model (Dreyfus, 2003) that preceded it, the stages of development for learners include:

1. Novice
2. Advanced Beginner
3. Competent
4. Proficient
5. Expert
The Dreyfus and Benner models were further studied and believed to be useful in a HCD learner’s context when compared to the insights from the longitudinal study and the feedback from the co-design sessions. The Design Competence Model, which identifies learning stages, was drafted and provided to the Catalysts, Coaches, and 15 other thought leaders and academics in the field of Human-Centered Design.

User feedback on model with Dreyfus and Benner context

Building on the prior user co-design session where a set of four generic stages were presented and refined (see Figure 1 and 2), a model adapted from Dreyfus and Benner’s models was placed into a new context for learning HCD. Now referred to as the Design Competence Model, the findings were presented to users and were believed to have usefulness and applicability in the HCD field for learners. When asked for the level of usefulness and applicability 75 percent of the users responded that the findings were highly useful and applicable. The users also believed that there was a stage not captured in the original models. This new stage occurred when an individual was first exposed to design as a relative outsider, not yet actively trying to learn the methods or mindsets. After a few more iterations, that activity was eventually codified into a pre-learning stage called “Contemplation” and added to the developing model.

Applicability of the Dreyfus and Benner models for HCD learners

The development of the model continued and was iterated with the same coaches, Catalysts, thought leaders and academics. The components are captured in the image below.

In the final model, it is noted that the Dreyfus and Benner stages were used with the addition of contemplation, a segmentation of learning into three broad categories of HCD methods of needfinding, brainstorming and prototyping, see Figure 3: Design Competence Model. Additionally, to demonstrate how learners were found to progress at different stages through these three categories of HCD methods, the possibility of varying stages of learners is shown in the second image of the model, Figure 4: Design Competence Model Demonstrating Example of Learner Development.
Design Competence Model displaying the potential of differing stages of development by method.
Description by stage

The Design Competence Model discussion will continue by further developing each stage of the model in comparison to the models from Dreyfus and Benner. Based on their models, this longitudinal study observes the development of individuals from the level of a novice with no experiential background in HCD to that of an advanced beginner who has experiences to draw from and eventually to what is termed as “competent” in some cases. Expanding this comparison, the coaches in the study would be considered in the final two stages of this skill development, which is proficiency and expert. The coaches are fully comfortable with the methods and have accumulated years of experience and the ability to more easily and skillfully navigate complex situations. Each stage is discussed briefly, along with the stage description from the work of Dreyfus and Brenner. Additionally, the study findings are included with each stage to provide a richer understanding of the learners’ experience as captured in this longitudinal study.

Contemplation

Dreyfus and Benner model: This stage does not exist.

Study findings: This is the point in time when an individual is exposed to HCD, possibly through a conference, internal workshop, educational course, co-worker discussions, or another source. During this time, a person may begin to see the connection between their personal interest, a problem they have to solve, and the possibility of design as an approach to help. If the experience is positive for them, they describe feeling mildly interested to highly interested and have gained enough motivation to be willing to invest a portion of time and money into deepening their exposure. They are often drawn to the idea of learning new approaches to solving problems because they are irritated by situations or conditions in their environment that are “irritating” and not functioning well, in their opinion.

Novice

Dreyfus and Benner model: An example of a novice in a clinical setting is a nursing student. Their behavior in practice settings is very limited and inflexible. Novices have limited ability to predict what might happen in a particular situation.

Study findings: The novice HCD learners were coached to keep making their projects “more manageable” in scope and complexity. It was stated by the coaches that this was because this would give them more time and ability to practice and iterate their technique. Structures that make it easier for people to practice in this way are important, such as easy access to patient advisory councils, or protected time blocks for project work. Positive feedback from others at this point appeared to be important for the learners as well as leadership support to feel progress and to continue the motivation and build the desire to begin to apply learnings into practice at a small scale.

Advanced Beginner

Dreyfus and Benner model: New nursing school graduates are an example of advanced beginners. They have more experiences that enable them to recognize recurrent,
meaningful components of a situation. They have knowledge but not a great deal of in-depth experience.

Study findings: The role of coach is important to guide application of learnings for practical skill development. Confidence develops slowly and occurs with repetition and successful demonstrations of techniques. Continued sponsor or leadership approval for time and resources during this learning stage is key, as learners experience that design methods take longer portions of time as compared to other methods and approaches they may have used in the past. A common language is developing between learners and coaches to enable deeper and more focused coaching and group reflection.

**Competent**

Dreyfus and Benner model: Learners at this stage recognize patterns and situations more quickly than advanced beginners, but are not as quick and proficient in problem solving and acting as proficient nurses. They can compensate with advanced planning and organizational skills if allowed the time.

Study findings: This stage can be fraught with frustration as the learner is developing competence in their skills but is still likely in the stage of legitimizing design skills to key advocates within their organization. Needfinding and brainstorming approaches are often more frequent in their practice development, but prototyping activities with users were observed as lagging behind and occurring less frequently.

**Proficient**

Dreyfus and Benner model: Situations for individuals that are at this stage can be viewed as a whole, instead of in separate parts. Proficient nurses, for example, can learn from experience about what events most typically occur. They can then respond quickly to modify plans in response when needed.

Study findings: If the learner reaches this stage they typically have strong internal organizational advocates and have often built a team of people who are attempting to model their design methods and skills. They have reconciled the similarities and differences between design methods and other approaches and can both speak to and advocate for their use when appropriate. They still need coaching at this stage, particularly when the work is complex or high risk.

**Expert**

Dreyfus and Benner Model: The experts no longer rely on rules to guide actions under given situations. They have an intuitive grasp of the situation and can rely on their deep knowledge and expertise. They also know which problems require their attention and which do not, and they only use analytical tools when they have no experience in an event or when events don’t occur as they had expected based on past experiences.

Study findings: Experts in this stage of HCD design methods have likely created an internal following of people, advocates and team members, who will evangelize the use of design methods with them. They can improvise methods in the moment based on what is needed and can contribute knowledge and approaches to continue to grow the practice.
They have formed a sustainable microclimate around themselves and their partners and often have a thriving network both in and out of their organization. (see “Learning from the Best: Unpacking the Journey of Organizational Design Thinking Leaders” from Zuber and Moody for additional context on experts and Microclimates.)

**Conclusion**

This study has sought to understand the journey of learning Human-Centered Design skills and to seek approaches to better enable this learning experience within the context of novice learners inside of organizations. The Longitudinal Study has examined individual learning and application of Human-Centered Design in a large, complex organizations over 12 months. Alongside the findings from the researcher’s PhD studies (Zuber and Moody, 2016), this allows the formation of propositions on the end-to-end learning experience and application of HCD within an organizational context. The findings are used to inform the development of the Design Competence Model for individual learners.

The perspective of an individual learning journey is novel and the study has offered a rarely seen view of the learning and application experiences of HCD within an organizational context (Seidel and Fixson, 2012). This has been explored to some extent by interviews with experts as they reflect on their changes in practice over time (Carlgren, 2013; Carlgren, 2014; Carlgren, et al., 2015; Carlgren, et al., 2016; Rauth, 2016; Leidtka and Ogilvie, 2011, Zuber and Moody, 2016). The approach applied here revealed that learning HCD skills may occur in a series of developing stages over time, and that HCD skills are highly influenced by the context in which they are being learned. The Dreyfus Model of Skill Acquisition and the subsequent Brenner Nursing Competency Model have been applied to the organizational HCD learner to create a novel view of HCD learning in stages.

This study has provided a deeper understanding of the personal and environmental factors as this experience takes place within the organization. The approaches discuss the iterative nature of learning, the active process by which it occurs and, the assertion is made that the learner becomes better skilled over time because of the comparative experiences. By adapting Dreyfus and Benner models, the stages of HCD learning take on a more distinct progression and development that did not previously exist in the design literature. It also provides insights into the experiences and needs of the HCD learner to enable leaders to provide better advocacy for the development and application of HCD for organizational innovation.

Author Biography

Christi Dining Zuber

Christi Zuber RN, MHA, PhDc is internationally recognized for her trail-blazing work in the field of innovation and design. She is a Principal of Innovation and Design at Kaiser Permanente, Founder of Aspen Labs consulting practice, as well as the Co-Founder of the global Design Thinking Exchange network. Zuber has over 20 years of leading teams, observing users, creatively generating ideas and conducting field experiments to develop solutions that work. She founded the successful (and joyful!) Innovation Consultancy which she led for 12 years. Their work has been touted by the likes of the Harvard Business Review, Fast Company, and the New York Times. Christi serves on The Conference Board’s Innovation Council as an Executive Board member and is a mentor to healthcare executives in an ASU sponsored fellowship program. In her current PhD work, she’s researching the secret sauce for change agents who have been successful in large complex environments and organizations that aren’t quite so keen to change. Christi loves to write, research, teach and speak on the topics of design, innovation, creativity and individual empowerment to make a positive difference in the world.

Collecting Insights from Experience Group Sessions™ to Better Inform Design and Strategy for a Pediatric Asthma Integrated Practice Unit

Sally Baek, Carolinas HealthCare System, Charlotte, USA, sally.baek@carolinashhealthcare.org

Abstract

The purpose of Experience Group Sessions is to identify the health and lifestyle challenges that make it difficult for patients and families to manage chronic medical conditions. The Innovation Engine at Carolinas HealthCare System worked with pediatricians to identify and recruit patients with chronic asthma. Experience Group Sessions were a way for families and patients to share their experiences managing asthma and allowed facilitators to gather insights about what does and does not happen in their daily lives. The key themes and quotes collected from the Experience Group Sessions were grouped into three categories of outcomes that define success with health: capability, comfort and calm. The results of the analysis were shared with the workgroup to inform the design and strategy for an integrated practice unit. Integrated practice units are intended to bring together a full range of providers and services to specifically address a certain medical condition, in this case, pediatric asthma at Carolinas HealthCare System. This integrated practice model will be reorganized around patient-centered care and value to improve overall health for children with asthma.

Keywords: Healthcare, Pediatric Asthma, Experience Group Sessions

In 2016, Carolinas HealthCare System’s Innovation Engine team worked with the pediatric asthma workgroup to facilitate three Experience Group Sessions based on the lessons from Elizabeth Teisberg and Scott Wallace. Elizabeth Teisberg and Scott Wallace, both currently at Dell Medical School at The University of Texas at Austin, pioneered the Experience Group methodology as part of their work to redefine and reorganize health care delivery around patient-defined value. This short paper describes the Experience Group Session process, Carolinas HealthCare System’s application of the Experience Group methodology, and the potential implications that helped inform the design and strategy for a pediatric asthma integrated practice unit.

Literature Review

An Experience Group Session is a small-group discussion in which people are asked about their shared experience living with a medical or life condition. This could range from what it’s like living with a chronic condition, to what it’s like to care for a family member’s medical condition, to what it’s like to work for a certain organization. Experience Group Sessions provide a way for patients and their families to explain what they understand about their
health, what they fear as a result of their diagnosis, and what they need to live a full life (Wallace and Teisberg 2014).

Experience Group Sessions are distinct from focus groups. In Experience Groups, participants are not asked to evaluate a product or service or to anticipate its market reception. Focus groups tend to ask questions like, “How do you like our product?” or “How was our service?” Experience Groups instead ask the question, “How are you?” The subject of interest is shifted from the provider to the consumer. In Experience Groups, the facilitators take more of a back-seat and observational role than the very active role they play in focus groups. The goal is for facilitators to create a natural dialogue between the participants, and for the facilitators to learn from the participants’ discussion. This is done by using “pastures of discussion” to explore a given theme for a period of time (Wallace and Teisberg 2014). Pastures of discussion are open-ended themes to prompt a conversation in a broad area.

Additionally, Experience Group Sessions have participants describe a particular dimension of their life from their perspective. The goal is to understand the patient or family’s current experiences and the individuals’ perception of their experiences. This discussion enables researchers to develop a detailed picture of the group’s current health experience, including barriers and enablers to achieving better health and life outcomes (Wallace and Teisberg 2014). Teisberg and Wallace say there are three components that establish great health care experiences:

1) **capability** to do what matters to people by restoring better functional outcomes, 2) **comfort** from pain and anxiety by restoring reduced burden of disease, and 3) **calm** that enables individual and family life by restoring reduced burden of treatment. To have an excellent healthcare experience, patients and families are seeking all three. When analyzing the outcomes of Experience Group Sessions, facilitators bucket the themes into these three categories to understand how to design products, services, and experiences to successfully achieve all three components.

This paper describes a case study on how the Innovation Engine at Carolinas HealthCare System used the Experience Group methodology to collect insights about chronic pediatric asthma management in order to better inform design and strategy for a pediatric asthma integrated practice unit.

**Research Methods**

In 2016, we worked with the practice manager at one of Carolinas HealthCare System’s pediatric office to identify two dates to facilitate the Experience Group Sessions. We planned on providing boxed meals and intentionally proposed lunch hours and early dinner hours to reduce barriers to participation. Once we agreed on the two dates, the practice manager reached out to the parents based on these two eligibility criteria: 1) needs to care for a child who is diagnosed with asthma, and 2) needs to live in a Charlotte area zip code.

When recruiting the participants, we asked the practice manager to reach out to potential participants through email or by phone. The invitation included information about: 1) target
Based on the advice from Teisberg and Wallace, we invited children to the Experience Group Sessions so that it would allow us to get a more complete picture of what it is like to live with and manage chronic asthma. For the initial two Experience Group Sessions, there were a total of seven parents and seven secondary school children who participated.

For both Experience Group Sessions, there were two facilitators – one primary note taker and one primary facilitator. The two facilitators identified three pastures of discussion using Wallace and Teisberg’s framework. The pastures of discussion were:

- What does asthma mean for the parent(s)? What are his/her needs?
- What does asthma mean for the child? What are his/her needs?
- If you could have one wish or wave a magic wand to help your child’s asthma, what would it be?

We developed these pastures of discussion with the input of the stakeholders from the pediatric workgroup and the operational owners. Operational owners are clinical or administrative service leaders who will carry the developed solution, service, or program forward once it becomes part of day-to-day operational processes. Essentially, they will “own” the solution that is developed based on the Experience Group Sessions and be responsible for the outcomes of that solution.

Once we received confirmation from the participants, we coordinated the logistics with the practice manager at the pediatric office. We had the first Experience Group Session at the Innovation Engine office, approximately 20 minutes away from the pediatric office. Because we asked participants to drive to a location that was unfamiliar, only one out of three confirmed participants showed up. In order to avoid the same situation, we worked with the practice manager and organized the Experience Group Session at the pediatric office for the second session in which all six participants were present.

For both Experience Group sessions, we facilitated the session by introducing ourselves as facilitators. We described the Experience Group process and then asked participants to introduce themselves by using only first names to ensure confidentiality. This process helped participants to get to know each other before beginning the discussion. Discussions started once the primary facilitator asked the first pasture of discussion, “What does asthma mean for you as the parent?” While the parents discussed, the primary note taker took careful notes of what stood out and memorable quotes. Both facilitators avoided being at the center of the discussion by playing the role of the observer and probing for more detail when appropriate.

After all the pastures of discussions were asked, we ended the session by asking the participants if they had any questions and thanked everyone for their time. We provided our business cards as a way for parents to know how to contact us if needed.

The next day, we debriefed and categorized the themes that arose into the arenas of
discuss the findings. She then typed all the findings into a Microsoft Word document. Afterwards, we determined it would be helpful to have one more Experience Group Session to solidify implications and to suggest next steps. We coordinated the third Experience Group Session with the same pediatric office a few months later.

**Discussion**

Based on the three Experience Group Sessions, we identified the following themes and supporting quotes:

- **Many, many unknowns:** None of the parents in the room said they had asthma. This made it especially difficult for parents to truly understand the triggers, symptoms and what signs to look for. One parent shared, **“The only thing I know [about asthma] is what I’m experiencing through my own kids.”** Part of the frustration for the “mama bears” who want to protect their child is that doctors don’t realize how little parents know about asthma.

- **Fear of the unknown:** One parent mentioned, **“There is a lot I still don’t know… I know how to use the technology [nebulizer/inhaler] but I don’t know what the triggers are.”** Another parent mentioned how providing a class on what signs to look for and what certain lung activities [ex: asthma attack] feels like would be helpful.

- **Around the clock management:** It was evident that the parents worried about their child’s asthma day and night. The child is the one experiencing the asthma, yet the parents are the ones constantly “listening for wheezing or rattling,” especially while they are sleeping. One parent mentioned “I want to keep her away and shield her from things that can trigger asthma, but not restrict her too much.”

- **Precaution and Fear:** Parents who take extra precaution sometimes wonder, **“Am I overreacting?”** but it’s hard not to do so when “the fear of death” and stories like, **“I know someone who died from an asthma attack because they didn’t have their inhaler”** forces them to take those extra precautions. **Every parent mentioned a fear about death as a result of an asthma attack because they had all known or heard of someone who died from an attack.** When asked what a bad day is like, one parent shared, **“A bad day is stressful. There is huge tension because I feel like I’m putting a burden on my child and I can’t fix it.”**

- **Seasonal transitions:** For the child, changes in the season, particularly the transition from the Summer to Fall and Winter to Spring is one of the toughest times to keep the asthma under control. **“I sneeze, cough and itch my eyes a lot at school… the Spring time is the worst and Summer is the best.”** For the parents, these transitions are the time when they start to regularly give their child preventative medicine like Singulair and Zyrtec®. **“I only give it [preventative medications] to them when the season’s really bad.”**

- **Magic wand:** When asked what they wish to help with pediatric asthma, the parents responded by sharing:
  - **“Delete it, make it [asthma] go away!”** [Everyone agreed with this sentiment.]
- “An on-boarding process for parents with children who are newly diagnosed with asthma…”
- “I need an education program. I’m terrified of finding information on the internet unless I really have to... literature was given, but it was a ‘figure it out yourself.’”
- “I’d eliminate the allergies because they are what lead to the asthma.”

The children responded by sharing:
- “Make everyday feel like Fall weather!”
- “Make me not slow down when I’m running [during PE class].”
- “I wish we had extra money for extra [asthma] medicine… those can get really expensive.”
- “Not have to worry about runny nose, coughing or itchy eyes.”

After identifying the key themes, we bucketed them into the three arenas: capability, comfort, and calm, shown in Table 1.

Table 1: Key themes collected from the pediatric asthma Experience Group Sessions

<table>
<thead>
<tr>
<th>Capability</th>
<th>Comfort</th>
<th>Calm</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keep up good grades and attendance in school</td>
<td>Increase knowledge about triggers &amp; symptoms so I feel in control.</td>
<td>Reduce the feeling of being dependent on medications</td>
</tr>
<tr>
<td>Enjoy social activities and feel normal (ex: sleepovers, play dates, gym classes, hugging grandmother)</td>
<td>Reduce my fear, guilt and tension. Know that my child is safe when I’m not present (friend’s house/school)</td>
<td>Reduce cost and number of medications</td>
</tr>
<tr>
<td>Participate in sports to greatest potential</td>
<td>Understand difference between symptoms caused by allergies vs. asthma vs. cold</td>
<td>Be less worried about my child’s asthma being treated properly when at school</td>
</tr>
<tr>
<td>Go to sleep, wake up in the morning and make it through the day without being triggered</td>
<td>Stay calm during asthma attack (parent and child)</td>
<td>Feel less restricted to do certain activities</td>
</tr>
</tbody>
</table>
Based on the findings, we presented potential implications to Carolinas HealthCare System’s pediatric asthma workgroup to inform the design and strategy for an integrated practice unit, similar to the one shown in Table 2.

Table 2: Potential implications based on the insights collected from the Experience Group Sessions

<table>
<thead>
<tr>
<th>Potential Implications</th>
</tr>
</thead>
<tbody>
<tr>
<td>“On-boarding” process and learning sessions for families</td>
</tr>
<tr>
<td>Social support and/or play groups for parents and kids</td>
</tr>
<tr>
<td>Improve communication between school, employer, home and provider</td>
</tr>
<tr>
<td>Support during moments that matter: the white space, change of season, new diagnosis,</td>
</tr>
<tr>
<td>the panic moment</td>
</tr>
</tbody>
</table>

**Conclusion**

Integrated practice units are intended to bring together a full range of providers and services to specifically address a certain medical condition, in this case, pediatric asthma at Carolinas HealthCare System. Unlike the existing fee-for-service health care model, an integrated practice model is reorganized around patient-centered care and value to improve overall health for children with asthma. In order to understand what patients value in their lives, customer discovery methods, like the Experience Group methodology, is a tool that helps providers understand the unspoken challenges that can affect a patient’s ability to get and stay healthy (Silverman 2017). As Carolinas HealthCare System continues to develop an integrated practice unit concept for pediatric asthma patients, the insights uncovered from these Experience Group Sessions will help guide the design and strategy so patients and families are able to feel more confident in their ability to manage asthma.

Changing the Perceptions of Making
Betsy Barnhart, Assistant Professor Department of Industrial Design Iowa State University Ames, Iowa, USA Betsy@iastate.edu

Kellie Walters, Department of Industrial Design Iowa State University Ames, Iowa, USA Kellie@iastate.edu

Abstract

Traditional Industrial Design sponsored studios (when a corporation partners with a student design studio) can quickly become design for hire studios which limit student learning outcomes as well as successful outcomes for the Sponsor. In assessing instruction practices in sponsored studios, traditionally success is limited to products moving directly into production. By reframing the studio into an incubator and in-line studio setting students could work in the same fashion as an in-house design studio, with mass diminutive ideation focusing on performance initially rather than aesthetics causing an increased standard for success. Because students would be concentrating on editing down a mass amount of variables with swift precision using raw but effective mockups, time would not be wasted on improving the craft of an initial, potentially ill-developed concept, leading to more risk projects with market disrupting potential rather than just an aesthetic or materials update going into production.

In a multi-disciplinary studio setting students from Industrial Design, Apparel Merchandising and Design, and Kinesiology, partnered with a corporate sponsored studio instructed in the framework premised above. The outcomes were a success with the studio functioning beyond a studio for hire scenario to learning objectives being met as well as aspects of projects moving forward into to development and projects moving directly into production as well as applications for patents. This paper investigates how studio culture can be reframed to create a diverse range of success as well as what specific instruction techniques, making techniques, and studio culture lead to this success.

Keywords: Ideation, Sponsored Studio, Design Strategy, Design Practice, Product Design, Innovation, Performance Driven Design

In the fall of 2016, the lead author led a sponsored studio at Iowa State University partnered with United Sports Brands (USB) (a multi-brand sporting goods corporation) specifically designing products for subsidiary Nathan Hydration. The studio was framed in a new way which changed the sponsors definition of success by having products ready for
production as well as concepts which were not finalized to the point of production but were proved to a point where it was worth investing in-house resources into as an advanced concept. USB benefitted in having products move directly into manufacturing as well as a multi-disciplinary innovation lab without as great of a financial investment and risk involved, while students had the ability to explore without the pressure of all products going direct to market. This academic sponsored design studio structured as an innovation lab showed that when students are given the space to pursue “blue sky” concepts with a limited brief and deliverables, but are encouraged to quickly create a mass of non-precious mockups to prove each statement they make and concept proposed, they are able to succeed not only within academic structures, but also professional practice.

Literature Review

In 2007, Design Council was asked to conduct a study assessing industry leading corporate design teams to assess what design processes lead to success. Within the specific section of text cited, Design Council performed an in-depth analysis through interviewing designers at 11 industry leading corporations and developed a framework based on consistency in their findings. They developed the double-diamond design process which has been coined and rephrased in academia (encapsulating discover, define, develop, deliver), and largely informs the design process we instruct students with. (London: Design Counsil)

Industrial Design Pedagogy versus Professional Practice

Traditional design classrooms present the design process following the double diamond design method (Design Council, 2007). Students are instructed to discover through research, to define with an opportunity statement, pursue development through ideation (combining sketching and prototyping), and delivery from refining their concept into a final product. Refinement usually consists of one to two rounds of three concepts being user tested and assessed into a final design. This is partnered with a competitive atmosphere where students are pressured to have the best critique. Students are assessed on the product’s ability to be immediately manufactured, market ready, highly crafted final models, process sketches, final renders, and graphic styles. With this framework, generally only specific aesthetic tastes with sketches, renderings, graphics, and photographs are seen as highly successful. Within in the process expressed to reach these final deliverables, students are also held to high standards of craft within their sketches and mock-ups, which can effectively lead to excessive amounts of time expended on ill-researched concepts without validating through user testing.

On paper, professional studios are structured similarly, since the double diamond method was coined from an in-depth study of successful in-house design studios (Design Council, 2007). The difference between the two is significant in how they are specifically enacted. Professional studios, due to production timelines and business pressures, are often forced to spend much less time on discovery, quickly find an opportunity within their product space, and move onto the first wave of ideation. Multiple rounds of ideation and refinement are pursued with performance validation until a handful of concepts are developed at a standard for user testing. From that point, designers assess findings in user testing, refine concepts further until projects are
developed enough for manufacture, meanwhile market and user research continue throughout and is interwoven within initial mockup and ideation phase. Within this process, the focus is not to have the best product or to have excellent reviews as academia pursues. Instead, the focus is on investigating partial segments of the overall design problem in order to systematically work through a project which could be overwhelming and not get caught up in a task which may be too large on the whole, but divided into smaller projects which are investigated in a quick decisive and rudimentary fashion. This method keeps initial ideation from becoming too precious and allows the designer to continue to move through other concepts without getting fixated on one idea. The process used in order to reach the standard set to manufacture is comprised of low-fidelity process to filter through ideas in order to spend less time on the craft of process and more time analyzing and moving forward with concepts.

Further Explanation of Sporting Goods Corporate Design Structures

Within professional studios in sporting goods, there are large corporations like Nike or Under Armor who dominate the market. These and other corporations are large enough to include dedicated in-house innovation labs to pursue “blue sky projects” (advanced concepts meant to disrupt the marketplace with an entirely new market, material application, and/or function) As sporting goods corporations rely on their reputation as being best in performance for their market to grow their market share innovation is a key aspect of their business. These key brands are large enough to holds a specific design team only concentrating their time on innovation and producing advanced concepts to change the current market space. Other medium scale or small corporations like do not have the expendable budget or risk allowance to pursue innovation labs in-house. The primary focus of the design work in these studios is on in-line products each year, meaning that once any “blue sky” ideation occurs, it is often not of primary focus, since the priority is to get the next phase of in-line products ready to go to market.

Research Methods

Classroom Structure

In the fall of 2016, the lead author led a sponsored studios at Iowa State University partnered with United Sports Brands (USB) (a mid-level sporting goods corporation) specifically designing products for subsidiary Nathan Hydration. The studio was framed in a new way which changed the sponsors definition of success from products ready for production to concepts which were not finalized to the point of production but were proved to a point where it proved potential and was worth investing in house resources into. USB benefitted in having a multi-disciplinary innovation lab without the financial investment and risk involved, while students had the ability to explore without the pressure of products going direct to market.

The concepts validated within traditional academic sponsored studios are a preselected amount of market ready products. The added interest in innovation and pursuit of “blue
“Blue-sky” concepts this studio allotted to also reward incubator concepts (ideas thoroughly researched and solidly based that have potential to be market disruptors) and elemental concepts (strong ideas that have elements that will go into production, but not the product overall). Having these three categories of concepts validated, created a beneficial set of outcomes for both students and sponsor. The student received experience working on both in-line products that need to be market ready, as well as “blue-sky” concepts. The sponsor on the other hand obtains a set of projects - fresh perspectives on in-line products and highly tested innovation concepts.

Students would have a multidisciplinary group and individual project to complete, for a holistic educational experience in both market ready and innovation products. Two group project options were available to students. One was to work on Nathan Wearable Hydration- a product where Nathan is the industry leader, meaning they face other companies being “market disruptors.” Nathan was looking for students to instead be market disruptors for them and was specifically seeking a new point of view, new material application, innovative function, and/or new market opportunities. The other group project option was in the wellness category, which was an entirely new market opportunity for the brand, meaning desired results included a solid category platform to enter the marketplace. Essentially students were answering the question: what does a Nathan wellness product look like? In the individual project category students could design Nathan everyday water bottles or work on the group project categories.

**Instruction**

For instruction methodology, the USB studio was operated resembling the structure a design manager would conduct studio. This meant that the students received a specific brief from the studio sponsor at the beginning of the semester with the projects previously described and had dates with broad deliverables for four student presentations to the client throughout the semester. There were set deadlines for each phase, only two weeks for initial research and for students to define an opportunity to pursue with the understanding that research would continue throughout the semester and would become more defined as their concepts narrowed. Following initial research students had three weeks to conduct a minimum of three rounds of at least 6 to 12 quick and rough mockups along with rough informative sketches. Each round were thoroughly reviewed, concepts were not discarded if they were not perfect, but were instructed to see if the idea had potential and to keep moving forward if so. In order to keep the ideation quick and also to prevent fixation on a single concept by the students they were instructed to use duct tape and staples, deconstruct existing products and quickly manipulate them to validate ideas. By shifting the focus from perfect craft to rough validation of initial ideas students felt comfortable trying out ideas which they weren’t sure would work and took more chances. Each round of initial ideation became more refined as students narrowed their investigations, by the time of their second presentation they had narrowed down to three well vetted concepts, instead of constructing via duct tape and staples they were sewing and using relatively close materials to what would be used in production, although focus was still not on aesthetics, performance was well defined and shown via prototypes and supporting sketches presented to the client. Students showed their iterative process and
the clear reflection through each stage of what was not working and where there was potential, which gained the trust of the client, especially for concepts which would otherwise have appeared risky.

**Student Evaluation**

As previously stated, there were three main product categories validated in this studio classified as: Market Ready, Incubator, and Elemental. Each project was not only validated on this criterion of general concept categories listed, but also based on feedback received from project managers at USB and Nathan Hydration through monthly presentations on research, concept proposals, form development, and final feedback. This kept studio from being academically biased and highlighted the notion of multiproduct, holistic studio success.

Students were required to have final renders, manufacturing files, technical drawings, final models executed well enough for a manufacturer to grasp, fully robust marketing campaign, and strong pitch. Validating student work was comprised of their results in the project manager’s eyes and in academic setting, their pursuit in process work, collation of their rigor in pursuing concepts, and how well classmates worked in a collaborative dynamic both in small groups, but studio overall. Academically, projects were rewarded for process and innovative concepts due to holistic pursuit in problem solving, rather than quality of sketches, fidelity of final renders, graphic styles, presentation layout, and a finalized design. These were requirements for final presentations, but instead of validating primarily from these variables, the pursuit of concept, specifically during the second phase of rough mock up iteration, determined the success of the project.

To validate whether this studio structure and instruction methodology was successful, Students and the client representatives were interviewed after the studio ended. Project managers from USB confirmed how many concepts will move forward within the framework of the three categories: Market Ready, Incubator, and Elemental. This was contrasted against the structure of previous studios, where a preselected number of projects would move forward into production. By using project progression into market as a source of validation, we are able to gauge how successful student work not only resembled work done in professional practice, but meant students were able to succeed within a rigorous professional practice setting.

**Results**

In total, there were 21 number of projects completed with 3 number of Market Ready products, 3 Incubator products, 4 Elemental products, and also included the application of 1 patent. These results were higher than not only expected studio outcomes from academia, but also surpassed the expectations of project managers at USB and Nathan Hydration. The student work presented not only fulfilled the requirement of collectively working together for group success and robustly pursued ideas, but had quality final models as well. Within the expectation of robust process work, they exceeded expectations.
This academic design studio partnered with a corporation, structured as an innovation lab and instructed like a professional practice studio showed that when students are given the space to pursue “blue sky” concepts with a limited brief and deliverables, but are encouraged to prove each statement they make and concept proposed, they are able to succeed not only within academic structures, but also professional practice. A year later, we interviewed several students from this studio who now work in the sporting goods industry who noted that the classroom structure and requirements left them not only with increased confidence in applying for jobs, but also prepared them for what it is like to be a designer in a professional practice setting more than any other studio had, this included AMD as well as Industrial Design students.

**Conclusion**

This study informed that in sponsored studios as well as general Industrial Design studio settings learning outcomes can be broader and more student centric than operating as a design for hire studio where stress of success may inhibit students from taking risks and limit their learning. In the next study, not only interviews will be conducted, but also pursue these questions through continued surveying of student opinions throughout the studio in concordance with analyzing their work to gauge not only if student opinion changes, but how their work, quality of work, and robustness of exploration adjusts throughout the semester.

In conclusion, traditional sponsored studios can cause students to fixate on a safe or initial idea. By shifting the framework of successful outcomes and by having students working in multiple tiers of rigorous creation of rough mockups leads to increased student and sponsor success. This study should inform Industrial Design pedagogy to operate its design studios with further robust exploration, and widen its perception of successful concepts to include Incubator and Elemental and not just Market Ready products.

Object Lessons: what is the value of engaging with the physical object within design research and education, evaluated through the application of the “Material & Process Innovation Collection”, at Manchester Metropolitan University Special Collections?

Stephanie Boydell, Manchester Metropolitan University Special Collections, Manchester, UK  mailto:S.boydell@mmu.ac.uk

David Grimshaw, Manchester School of Art, Manchester Metropolitan University, Manchester, UK mailto:d.grimshaw@mmu.ac.uk

Abstract

Throughout the history of design teaching in Higher Education, there has been an assumption that students need to physically encounter objects to fully understand and appreciate them.

However, in this digital age, the physical encounter has been superseded by the myriad detailed images and information that is readily available on-line and in print.

This concern drew together a museum curator and a 3D Design educator. One was concerned that the digital experience lacked the visceral and emotional experience of engaging with physical objects, and highlighted a difficulty of facilitating access to meaningful, contemporary, objects. The other, whose largely historic collections were increasingly considered “irrelevant” to contemporary design practice, understood the value of materiality as fundamental to a museum’s existence, and its role in teaching and research.

The result was the establishment in 2013 of the “Material & Process Innovation Collection”, a museum quality collection, comprised of objects that are cutting-edge in terms of their material and process-led approaches to making, manufacture and distribution. The collection is driven not only by curatorial concerns, but by teaching and research, challenging the conservatism of museum collecting by taking innovative objects of untested materials and unknown makers, and hands the responsibility of collections development to non-curators.

The research presents an analysis and reflection on bringing the physical back into the classroom, the value of this experience within teaching, learning and research, and reveals if
there is merit in the assumption that sensory engagement with physical objects is of greater value than the digital experience.

Keywords:
Education
Museums
Collections
Materiality

Introduction

The prima facie idea that good design education necessitates access to physical objects was central to the establishment of the British Schools of Art in the mid-19th century. It was also the rationale for the foundation of their associated museums such as the South Kensington Museum (now the Victoria and Albert Museum, London) and also the Manchester School of Art’s Arts and Crafts Museum (now Manchester Metropolitan University Special Collections), which opened in 1898.

After 150 years of educational and museological theory, this idea is still current amongst educators and curators. Much has been written on the subject of experiential and “Object Based Learning”, but the rise of digital access and virtual experience has overtaken physical interaction with objects in the classroom and in the museum. Student claims to “research” using applications such as Pinterest and Instagram may be narrowing their experience of their field of study, in particular in the field of 3D design, where materiality is fundamental to the product/design, and where virtual representation cannot allow for testing of size, weight, functionality, etc.; all essential aspects of the design process.

For the university museum, keeping collections relevant to teaching and research, and ensuring their continued use, is vital if they are to stay open in these cash-strapped times. Their point of difference to web sources, and their raison d'etre, is in the acquisition, care and use of physical collections: materiality is key to their existence.

Context & rationale for the “Material and Process Innovation Collection”

In 2010, a postgraduate student on placement with MMU Special Collections conducted a short survey of teaching staff at the Manchester School of Art asking why they did/did not use the collections in their teaching. There was a core of staff who valued the collections and used them on a regular basis, and this was a means to discover why others did not. One vocal respondent who did not use the collections was David Grimshaw, a lecturer in 3D Design.

MMU Special Collections was founded in 1898 to give students of the School of Art (and the Manchester public) access to what was considered the best of contemporary craft and design and it remains a rich resource for teachers, researchers and students to this day. Although it has been added to over the years, Grimshaw’s concern was that the collection was primarily historical, and
did not include many pieces or products from contemporary designers and makers. Whilst the value of studying objects from history was not denied, he felt that the collection did not fully engage students who were inspired by images of contemporary pieces seen online, and which better reflected their own ambitions as designers and makers.

Grimshaw had staffed many study trips across Europe, and experienced at first-hand many pieces that embodied the advances in making and production being developed within contemporary craft and design. In his teaching, it was images of these that were used as examples to inspire students, not works from the university’s own collections. However, Grimshaw felt that the images never truly communicated the physicality of the work, nor the excitement felt when seeing them “in the flesh”.

For Boydell, who was fully aware of the collections history and current role as a resource for staff and students, it was concerning to learn that the collections didn’t meet the needs of these primary users. Both recognised that there was a gap in their professional delivery which might be met by the others involvement.

This led to an initial project, an exhibition in the MMU Special Collections, curated by Grimshaw. The Language of Process: how new materials and technologies are changing product design\(^1\) (23rd September 2013 – 20th December 2013) focussed on the innovative use of materials and process within contemporary design. It presented work where new materials and technologies were changing the production, form and language of contemporary designed and made objects. Some of the objects selected for display were borrowed, but others were purchased using the Special Collections acquisitions budget.

The exhibition was a great success, and the excitement of directly experiencing contemporary designed objects was highlighted by the reaction of students, staff and visitors to the exhibition, evidenced by some wonderful feedback.

**Establishing and developing the collection**

As a result of this there was increased use of the collections in teaching, bringing in different departments and making the collection visible to staff across the faculties. In terms of collections development for the museum, the contemporary craft and design collection was now up to date and relevant.

At the close of the exhibition, the purchased works entered the permanent collections and formed the basis of a new contemporary collection entitled “The Material and Process Innovation Collection”. This collaboration between academic staff and curatorial staff was seen as so successful it was decided to extend that model and continue the contemporary collecting into the following year.

\(^1\) For the full exhibition catalogue see [www.specialcollections.mmu.ac.uk/files/langproc_catalogue.pdf](http://www.specialcollections.mmu.ac.uk/files/langproc_catalogue.pdf)
To broaden the range of works acquired, a collecting panel of senior academic design staff from across a range of design practice and academic disciplines was established, and a collecting policy established to focus purchasing decisions. (See Appendix 1).

To take advantage of the expertise of the full range of educators, designers and makers in the School of Art, all staff were invited to recommend works for acquisition and the collecting panel would make a final selection based on the collecting policy and the limits of that years’ budget. The collection therefore represents current interests and trends within design and making. It is an annual snapshot of contemporary issues and concerns of designers and makers, highlighting their responses to new materials and technologies, as they are innovated, developed, and finally become established as everyday tools of making and manufacture.

As such, the collection is extremely reflective of current design thinking, with many of pieces reflecting moments that come and go, becoming “outdated”, but capturing fleeting concerns in a way that a more long term and reflective collecting policy would not.

This is however an unusual approach to collecting for a museum to take. In terms of collecting, museums are traditionally risk averse. Many are concerned that objects acquired should be of “museum” standard, a value that only accrues through time and external endorsement. Boydell and Grimshaw realised very early on that the aims of this collection could not take that stance and had to embrace the possibility of objects “losing value”, even collecting material that we knew may not physically stand the test of time.

Importantly, the collection continues to be used in teaching across a wide range of courses within Art & Design. It enables students to have physical interaction with pieces they may have only previously seen on line or in publications, and provides them with the full sensory experience that isn’t possible through purely visual communication methods.

Boydell and Grimshaw wanted to qualify this somehow, to prove the value of the collection to the university. In February 2017, student feedback was sought after attending a series of handling sessions for both undergraduate and postgraduate students. We wanted to know if students felt the experience had value above that of viewing the same work online and if it had affected their thoughts about the work, their ambitions, and their approach to research and development of their own work.

**Student feedback**

The value of experiencing the physical is a primary concern to educators within art and design, and is fundamental to the existence of museums. However, with the growth of online information, and the development of virtual reality (VR), is this still the case? Does the contemporary generation of young designers and makers actually see value in physical experience of work, over and above the experience they get by viewing 2D and 3D images online? Are the presumptions of lecturers and curators the concerns of an older generation, out of touch with the power of digital information to inform and inspire the next generation of designers, or do young students actually value the experience and information they gain from handling these physical objects?
The feedback to the multiple-choice questions was statistically revealing, with most of the feedback reflecting that the experience had been “Very Useful” to “Essential” (For feedback questionnaire see Appendix 2).

Figure 1. Compared with viewing objects as images, how informative was experiencing the physical object in enabling you to…:

Figure 2. Compared with viewing objects as images, how useful was it to…:

However, it was the free text comments that most supported our supposition that the value in engaging with physical objects would have significant effect on how they thought about the work of other practitioners, and their personal decisions and ambitions for their own creative practices. Most interestingly, these were reactions
that would appear the students had not expected themselves, and many weeks after attending the sessions, they could still recall names of practitioners and key pieces that had been of inspiration to them.

When asked if there were “any particular work(s) in the collection that you recall, or that stood out, and why?” some of the respondents remembered key practitioners such as Formafantasma, Dirk Van de Kooj and Gareth Neal, eloquently commenting on the memorable experience of handling the work:

“Seeing objects in galleries is always a little frustrating to me though as I want to pick them up and inspect them properly from all angles. When I found out that one of (Formafantasma’s) Bone Jugs was in Special Collections I was so excited as this meant I could actually handle the object I had been so inspired by” … “Being able to pick up the jug, handle it, see it from all angles and inspect exactly how it had been put together was really useful for my practice and I felt really lucky to have that privilege.”

“Overall, the broad diversity of products within the collection enabled me to become better educated in the wide variety of design, manufacturing techniques and practitioners from past and present. I have been able to draw inspiration from many of the pieces, which has then enabled me to discover more and has given me a better platform for future endeavours, post course.”

“Dirk van der Kooj’s chair – allowed me to visualise and understand the process of construction”

“It has made me further aware of how instructive seeing an object first hand can be and how it is crucial to develop an understanding of the object. I will make more effort to make visits to places where I can have similar experiences.”

“I recall very well the Dirk Van de Kooj work and really understanding how impressive its construction was. And also the digital candle which I felt I understood way better in person.”

“The Bloom Table Lamp by Patrick Jouin, because it was 3D printed in one process, I could see the detail and structure better by viewing it in person. This provides deeper understanding of how it works which impressed me a lot.”

When considering if the “experience of seeing and handling physical objects (would) change your approach to researching objects and products, and if so how?”, the students appeared to have become more aware of the value of going to see physical objects in person, and not relying on the internet or image collection sites such as Pinterest, to view work:

“Yes, definitely, as it enabled me to engage with the object more. When researching artist’s work, I tend to flick through many photographs of their work, but perhaps don’t fully engage with the work. Seeing the physical object, especially seeing one object at a time, enables me to engage with the work, interrogate it, inspect it, question it and feel like I’m undertaking research of high quality.”
“Yes. It was obvious to me that when I actually looked at an object with a view of seeing how it was manufactured etc., it was so much more beneficial than looking at it on a screen. You’re able to compare and contrast with other objects because you can see it in detail. Images do not provide this benefit.”

“Handling pieces has shown me the value in designing and manufacturing products that are pleasurable to handle. Additionally, it has shown me techniques to avoid/deeply consider due to their fragility, weight or longevity.”

“It reinstated the value of seeing something in person like going to a gallery museum or shop.”

“The hands on aspect allowed me to visualise potential areas of difficulty in the manufacturing process. It also allowed me to get a feel for the weight and worth of the objects.”

“Yes, especially mycellium. First-hand experience is essential. A picture cannot always tell a thousand words.”

“…it did highlight how important it is to touch and feel an object as this can alter your opinion of it.”

“I always like to see a piece ‘for real’ and, if possible, handle it. Publications and online research are not the only one way to find answers.”

When asked about the impact on their own work, and whether “experience of handling and viewing physical objects, (would) change or develop the approach or understanding of your own work while a student, and if so how?” it was again interesting how their reactions to handling the collection made them consider both their own work and how other people would react to it. It raised interesting considerations, from the practical and pragmatic, to the philosophical and theoretical, and raised issues not considered before taking part in the sessions:

“I feel objects should either be designed with function as the number one priority, like a really well designed kitchen utensil, or designed to be piece of artwork. To me, function should never be a secondary priority when designing. If I had just seen photographs of the Bone Jug I may have assumed it was fully functional, but being able to handle it in person enabled me to discover its flaws in functionality. This didn’t make me like the object less, as I love it for reasons besides its functionality, but it did help me further understand how I feel about functionality, and in turn, assisted me in developing my own practice.”

“…it made me realise the potential for working with CAD/CAM, before I felt that you don’t have to engage with CAM process as much as you actually do, I felt you just press ‘go’ and that’s it”

“It provided me (with) broader inspiration and choices of production process while I am developing my work. Giving me intuitive feelings of products and helping me consider design concept more figurative and realistic.”
‘(I’m) inspired by hands on design, scale prototype, order material samples to get a ‘feel’ before applying to product.’

‘I guess it gave me a standard or a benchmark of what mass produced furniture looks like. Not so much with the craft objects because how you want it to look is a lot more subjective in my view.’

The final question asked whether the experience had any longer term impact on their career ambitions. “Did the experience of handling and viewing physical objects, change or develop the ambitions or focus for your future career, and if so how?” Remarkably, the relatively short experience of a half-day handling and discussing contemporary designed objects made a deep impression and potentially changed their creative futures:

“Yes, there is something I find really inspiring about handling a piece of work that has been created by designers who I aspire to be like. It sounds kind of silly, but handling artwork in the reading room as opposed to seeing flawless, professional photographs of artwork makes me feel like success is more achievable”

“I believe it probably gave me something to work or aspire to. Mass produced furniture is the route I want to go down so seeing some high quality objects allowed to produce a better idea in my head of what the standards are. Seeing and touching objects (especially the sort you’re interested in) is essential to furthering your design instead of looking at them on the computer. You get a much firmer grasp of what to expect in the real world when you do this."

“I believe the Special Collections is essential for the university. I have had the luxury of being able to attend design shows in London, Eindhoven and will be attending Milan in the April. For students who cannot attend these design shows or get a personal experience with products, the Special Collections gives them that opportunity. If anything growing it more would be a must. Lectures referencing objects and telling students they can go and physically interact with them on University premises is fantastic. Increase collection!”

“It opened my eyes further as to the innovative materials and processes that were being created out there in the design world.”

“Previously I was focused purely on furniture. Now, thanks to the collection, I am interested in full collections, including lighting. My aim is now to design for the home, for a lifestyle, not just standalone items.”

“It makes me think further about my future career, moreover, it develops my focus in specific area such as production process and material use. In addition, by viewing those collections, some of them really broaden my mind about product design, that’s really helpful while I am developing my personal ambitions.”
**Conclusion**

Unfortunately, only 11 students responded to the survey, and while we know that this sample is too small to draw any significant conclusions from, it does give us some indication that access to physical collections does influence student practice. The answers raise more questions and we hope that the work that has been done here will form the basis of a larger and more focussed study in the future.

Similarly the development of collections using a large pool of expert suggestions, looking at material that speak to the “now”, not collecting with the established canon in mind, is not a risk, but a venture into collaborative collections development that has enriched the museum for both current and future users.

**Author Biographies:**

**Stephanie Boydell, Manchester Metropolitan University Special Collections**

Stephanie Boydell is Curator at Manchester Metropolitan University Special Collections.

Stephanie has worked in the museum sector for nearly 20 years. Her main focus is now exhibitions and collections management, and ensuring that the collections are used to support teaching and research in the university, as well as being open to the wider public.

She has a background in art and design history and some specialism in nineteenth century British art and design, as well as contemporary crafts and design. Stephanie has curated many exhibitions and has edited the following books: ‘A Japanese Passion: the pottery of Edward Hughes’; ‘Firing Thoughts: the relationship between ceramics and drawing’ and ‘Ravilious in Print’.

**David Grimshaw, Manchester School of Art**

David Grimshaw is Programme Leader for MA/MSc Product Design at Manchester School of Art, and previously programme leader for BA(Hons) 3-Dimensional Design, the course he graduated from in 1989. Based in Manchester, David established himself as a freelance design consultant for contract furniture, designing ranges for top end UK manufactures such as Viaduct, Allermuir and Davison Highley, before returning to Manchester School of Art in 1997 to teach.

Informed by his background as a material led designer for manufacture, his research investigates the relationship of digital design to material making, challenging the perceived perfection of the virtual and the digital, and its translation into material reality. Focussing his investigations on CNC routing, he seeks to explore the potential for craft material and making knowledge to inform a more sensitive and exploratory use of tools within the physicality of digital making.

David brings over 25 years of practice and teaching knowledge within design, craft, manufacturing and making, to inform the current debate on the sustainability of materially led craft and design practice, when society and educational establishments appear increasingly convinced that the future is digital.
Appendix 1

Manchester School of Art Collection: the Contemporary Craft and Design (Material and Process Innovation) collection. Taken from MMU Special Collection Collections Development Policy, 2014.

History:

The Manchester School of Art Collection has a long history of collecting contemporary craft and design since the 1890’s. It is an area which we are continuing to develop to meet the changing needs of the teaching staff and research groups of MMU, and in line with the university’s and the School of Art’s concerns with digital futures.

The exhibition *The Language of Process: how new materials and technologies are changing product design*² curated with David Grimshaw (Programme Leader for BA 3DD and MA/MSc Product Design) inspired the collection of a group of objects which use digital and emerging technologies. It is an area in which we understand that we are unique in collecting in the region.

Whilst we often work with teaching staff and researchers from the university for advice and guidance with acquisitions, in 2013 we made a more formal arrangement with regard to collecting contemporary craft and design by establishing a collecting panel, comprised of staff from the School of Art and the Craft and the Design Research Network in MIRIAD (Manchester Institute for Research In Art and Design). Members of the panel are Professor Stephen Dixon (ceramicist), David Grimshaw (product design), Dr Jane Webb (design historian) and Dr Annie Shaw (textiles). The curator of the Manchester School of Art Collection is included on the panel, but only as advisor (ie only to suggest feasibility for storage/costs, make sure it meets wider MMU Special Collections objectives, etc).

In this way we can work closely with leading figures in this field to keep the collection relevant and contemporary. This makes the process of contemporary collecting more transparent, whilst acknowledging and taking advantage of the expertise held in the school, and reflecting the needs of our core users.

Whilst the panel can itself recommend items for acquisition, any member of the University teaching and research staff can make suggestions to the panel.

A small budget has been set aside annually for the purpose of acquisition. This is determined by the annual budget allocated to MMU Special Collections as a whole.

The intent of the acquisition is not only to meet a need for relevant and contemporary material that informs teaching and reflects contemporary practice beyond the Higher Education sector, but also to build a public collection of contemporary craft and design that is unique and unmatched in the region.

Description:

² Manchester Metropolitan University Special Collections Gallery, 23rd September 2013 - 20th December 2013

Themes for Collecting:

1. Items can be craft or design, a one-off or mass produced piece
2. Items can be any media (including items made from untested, new materials that may deteriorate, and digital media)
3. Items can be international in origin
4. Items must have been made or designed within the previous 5 years
5. Items that embody contemporary/cutting edge concepts and practices
6. Items must reflect current teaching and research concerns of the Manchester School of Art and/or MIRIAD
7. Items that reflect contemporary practice beyond the Higher Education sector
8. Items that build a public collection of contemporary craft and design that is unique and unmatched in the region
Appendix 2

Feedback questionnaire

(Multiple-choice questions to be answered with the following responses: i. Not informative; ii. Less informative than images; iii. The same as viewing images; iv. More informative than images; v. Essential)

1. Compared with viewing objects as images, how informative was experiencing the physical object in enabling you to:
   a. Understand the material and process of making/manufacture?
   b. Understand the construction of multi-part/multi-material objects?

2. Compared with viewing objects as images, how useful was it to:
   a. View the work from multiple angles?
   b. Feel the weight of the work?
   c. See and feel the surface finish or texture of the work?
   d. Smell an object?
   e. Help you decide what your overall feeling about an object was? (Free Text Questions)

3. Was there any particular work(s) in the collection that you recall, or that stood out, and why?

4. Did the experience of seeing and handling physical objects change your approach to researching objects and products, and if so how?

5. Did the experience of handling and viewing physical objects, change or develop the approach or understanding of your own work while a student, and if so how?

6. Did the experience of handling and viewing physical objects, change or develop the ambitions or focus for your future career, and if so how?
A Study on Design for Diagnostic Tool for Language Processing Ability with Aging - Focused on ‘Verb naming’

Yoo Mi Choi and You Ri Kim, Division of Design, Ewha Womans University 52, Ewhayeodae-gil, Seodaemun-gu, Seoul 0376,0 Korea, yoomi@ewha.ac.kr; iamurikim@gmail.com

Abstract

The deterioration of linguistic abilities is a natural phenomenon along with aging. Therefore, various assessment tools have been developed to measure linguistic abilities of seniors and diagnose degenerative diseases such as dementia. Although most of the tools are composed of images, there are not many studies focusing on the visual design, which could significantly affect performance of the subject. In this regard, this research aims to suggest a design guideline for linguistic ability assessment tools concerning the key characteristics of the elderly, focusing on visual contents and interface.

Existing related researches were mostly conducted in English-speaking countries. In order to assess the language processing abilities of Korean-speaking elders more accurately, it is necessary to develop language processing assessment tools that reflect the unique linguistic features and structure of the Korean language. Regarding the existing tools, there is a lack of research on aging, focusing on ‘verb naming.

In the literature review section, the paper investigated the physical, cognitive and emotional characteristics of the elderly and extracted the key elements to consider when designing for the elderly. Also, design principles were found based on case studies and problem analysis of the existing assessment tools for language processing abilities. Lastly, we created a prototype model using ‘verb naming.’ Using the model, we have conducted an experiment and comparative analysis between different age groups to verify the validity of contents.

In conclusion, we provided a design guideline for visual contents and interface of linguistic assessment tools, focusing on elderly users.

Keywords : Elderly Adults, Language Processing, Assessment Design Guideline, Interface Design, Animation Contents, Elderly Design

Introduction

Various research on the decline of language processing ability along with aging has been conducted, mostly in English speaking countries(Caplan, DeDe, Waters, Michaud, & Tripodis, 2011; Waters & Caplan, 2001; 2005). Assessment tools for language impairment that can diagnose the early progression of degenerative diseases such as dementia have been developed. However, despite the fact that most of the diagnostic tools are composed of image contents,
there is a lack of research on visualization design of contents, which can affect performance. In addition, most of the researches related to degradation of language processing ability are conducted in English. Therefore, to accurately examine the declining of language processing ability among Korean users, it is necessary to develop a language processing task that reflects the characteristic structure of the Korean language.

Currently, most of the diagnostic tools for diagnosing language processing abilities are focused on the 'Noun naming' research, and there is limited research on 'verb naming' related to aging. Jee Eun Sung, Eun Jung Kwag (2012) produced an animation consisting of 8 frames of black and white lines, and used it as a naming task for the verb. According to this study, the verbal naming ability of different age groups is differentiated by the argument structure. However, there is no study on the correlation of cognitive abilities perceived by the elderly.

The purpose of this study is to suggest guidelines for contents and interface design of language ability diagnostic tool while considering characteristics of the elderly. Among them, we would like to present an optimal visual contents style focusing on the task of 'naming the verb'.

Research Methods

In this study, first, literature review was carried out through previous studies related to the biological and cognitive characteristics of the elderly and research on theoretical data. In addition, we examined research on the language ability diagnostic tools currently in use. Based on the collected language diagnostic tools, we analyzed the elements that should be considered in the design aspect, suggested the first interface design guideline, and made a prototype of the 'Verb naming' diagnostic tool in line with the principles.

We carried out the user test among 32 participants, 16 in the younger age group (aged 20 ~ 39) and 16 in the elder age group (age 65 ~). Tests were presented on a portable computer in a one-to-one situation, and prototypes of four stimulus types for each verb were presented in random order for each subject. Based on the experimental results, we revised the interface design guideline for language ability diagnostic tool considering the characteristics of the elderly.

Literature Review

1. Biological and Cognitive Characteristics of the Elderly

This study classified elderly people over 65 years old based on labor law standards. Elderly people undergo a lot of changes in terms of biological and cognitive aspects. Hong Suk-jae (2010) suggests that aging reduces sensory experience by slowing sensory organs, which reduces opportunities for external recognition and makes communication difficult. According to Jin Hee Chun (2003), along with aging, the ability to perceive saturation weakens. Therefore, the elderly perceive orange as red or purple, green as blue, and blue as indigo, while purple is perceived as purple without discoloration. Also, dark colors such as brown seem to be closer to black, and they may not perceive the small differences in brightness. In order to increase visibility and discrimination, Arthur, P., Passini, R. (1992) stated that the difference in brightness between figures and background should be clarified when considering older people. In addition, older people have difficulty adapting to sudden light changes and are vulnerable to light reflections, so light brightness is an important visual consideration when content is embedded in digital devices.
1.1. Design Elements Influenced by Changes in Biotic Sensory Function
We have identified the main design elements as line, shape, color and layout. When using the line, it is necessary to avoid the use of thin lines, which is difficult to perceive for the elderly. You should use simple shape and refrain from using patterns in shapes. Elderly people need clear guidelines for color usage because they are less able to respond to changes in color brightness and saturation. It is recommended to use colors such as red and orange in the long wavelength series, and they should be used properly considering the meaning and purpose of each color. It is also good to avoid using blue for important features as there could be yellowing of the blue color among the elderly. The arrangements and layout should be simplified and easy to understand. It is better to use a simple, iterative layout rather than a complex and diverse layout. Leave margins as much as possible, and do not stack elements together.

1.2. Interface Components Affected by Cognitive Characteristics
Interface components influenced by cognitive characteristics of older people are defined by type of contents, and interface. For type of contents, as elderly people have difficulty in recognizing temporal resolution stimuli, it is better to prohibit the use of moving images. If you use animation or video clips, it is better to use it repeatedly. When designing interfaces for elderly people, users should be allowed to control the size of the contents themselves. It is recommended to provide a touch interface method rather than a mouse operation method.

2. Current status of Diagnostic Tool for Language Processing Ability

2.1. Visual Problems of Currently Available Language Processing Diagnostic Tools
The design elements and the interface components were analyzed for three main language ability diagnostic tools (Figure 1,2,3) currently in use.

Figure 1: Understanding & Discriminative Noun Test for Language Therapy (Hu&Yu Hospital)

Figure 2: Daegu Aphasia Diagnosis Assessment Tool (Jung, Ok-Ran)
We have analyzed the visual contents problems of the existing language processing diagnostic tools. The results are as follows:

a. Unconstrained visual complexity: In the case of overly complicated visual contents, the visibility of the core information is degraded, and if it is too simple, the concentration may be reduced.
b. Inconsistent expression methods: Presenting different styles of contents within the same task can give users a visual fatigue.
c. Using overly infantile forms: The use of overly infantile forms or the use of sophisticated styles tailored for young users lowers objectivity and reliability as a diagnostic tool for the elderly.

**Discussion**

1. Prototyping

1.1. 'Naming Task for the Verb' Content

First, visual contents showing certain movements or actions are presented to the participant, and then the participant describes the movements or actions with their own verbal expressions. The Korean 'naming the verb' task used in this study consists of 4 types, in total 24 verbs, composed by Su Jin Choi, Jee Run Sung (2014). For prototyping, verbs of each category were selected based on frequency of use and representativeness. Among them, four verbs were selected - fly, melt, blow / turn off, and give (Table 1).

1.2. Media and Contents Representation

According to Sunyee, Park., Hochun, Choi. (2011), illustrations can be classified into realistic illustration, abstract illustration, hemispheric illustration, characters and symbolic illustration, and surreal illustration. In this study, we chose realistic line illustrations for the elderly with
low cognitive abilities.

1.3. Prototype Type
The prototype of each representative verb is composed of four components: cut image, sequence image, normal speed animation, and slow speed animation (normal-speed of 120). It is made in achromatic color with a high brightness contrast for the old age group with low color perception. We used the universal and realistic form, and reduced decorative features. Also, we used simple layouts and generous margins. Reflected light is applied to the whole background in consideration of the elderly who have difficulty adapting to light reflection (Figure 4).

![Prototype Image](image)

**Figure 4: Prototype**

2. User test design

2.1 Subject
This study was conducted for 16 young people aged 20 ~ 39 and 16 elderly people aged 65 or older only as a control group for comparison of results.

2.2 User test procedure
Before proceeding with this test, we provided detailed instructions and made them practice to make sure that the subjects understood the contents accurately. Prototypes of the four stimulus for each verb were presented in random order to each subject. Each subject took two tests and the subjects were given enough time between the first and second so that the first test did not affect the second test.

2.3 Test rule
For each question, 1 point is given for correct response and 0 point for false response. The subjects were provided with a maximum of 15 seconds per question and if no response is given within 15 seconds, or if the subject requests to repeat the instructions, an additional 15 seconds are provided after repeating the instructions again.

A total of two repetitions per question is allowed and if the subject does not respond after the second instruction repetition, it is treated as a false response.
2.4 Analyze test results

The user test was analyzed by two factors (performance and cognitive time). The results are as follows.

Performance: Correct reaction, false reaction (1 point for correct reaction, 0 point for false reaction). Cognitive Duration Time: The time measured until the target verb was spoken.

<table>
<thead>
<tr>
<th>Table 2. Inter-group performance results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cut Image</td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>Old</td>
</tr>
<tr>
<td>Young</td>

<th>Table 3. Time spent between groups (unit: second)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cut Image</td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>Old</td>
</tr>
<tr>
<td>Young</td>
</tr>
</tbody>
</table>

In the case of performance (correct or false response), there was no significant difference between the two groups for all four types of stimuli (Table 2). However, in the case of response time, young people responded within 2 seconds in average for all types of stimuli but the average response time for the elderly were significantly longer than the young. The minimum time was 3.84 seconds for slow speed animation, and the maximum time was 6.34 seconds for sequence image (Table 2). In average, the elder responded faster when the stimuli was in animation than in images, and it took the longest to respond when presented with sequence image.

Therefore, based on literature review and test results of the prototypes above, we suggest the following guidelines for contents and interface design.

</table>
Conclusion

In this study, we first examined the physical and cognitive characteristics of the elderly, and then analyzed the problems of the 'naming task for the verb' which is one of the existing diagnostic tools of language ability, and presented contents and interface design guidelines for language assessment tools focusing on characteristics of the elderly.

Based on these design principles, we created prototypes and conducted user tests among two different age groups to revise the design guidelines suggested in this research. The results show that the average performance rate of 'naming task for verb' between two groups were not significant between the two groups. However, there was a significant difference in the response time between the two groups for all four stimulation types. Moreover, for the elderly, the speed of cognitive recognition was fastest when presented the stimulation was presented in the slow speed animation form. This suggests that the speed of animation can affect the speed of cognitive response among the elderly.

This study has clinical significance in that it presents basic guidelines for future research on contents and interface design for language ability diagnostic tools. However, there are some limitations and avenues for future research. First, we have only tested 4 verb types among 24. Second, the number of participants (32 in total) for the testing seem to be relatively small. Third, we divided the age group into two groups, but it could be divided into shorter age-span groups to analyze differences in performance and response time along with aging, in the future.

**Author Biography**

Yoo Mi Choi

Yoo Mi Choi is a Professor of UX Design at Ewha Womans University, Seoul, Korea. Her main research areas are computer animation and digital contents using various new technologies such as augmented reality, stereoscopic 3D technology, etc. She received her M.F.A. in advertising design from the Graduate School of Design at Ewha Womans University and M.S. in computer animation from Texas A&M University Visualization Science Lab. She was the Chair of the Design for Woman’s Concern Association and the Animation Society of Korea. She has published over 30 academic articles in various journals.

You Ri Kim

You Ri Kim received the B.S. degree from Media Interaction Design, Ewha Womans University, Seoul, Korea in 2012. She is currently pursuing the M.F.A. degree in the Department of UX Design from Ewha Womans University. Her research interests include Graphic Design and GUI Design.
Future Propositions for How People Use Technology: Designing Through Ethnographic Research Methods

Carly Burton, Cognizant, New York, USA, carly.burton@cognizant.com
Wayne Chung, Carnegie Mellon University, Pittsburgh, USA wcchung@cmu.edu

Carnegie Mellon University's School of Design partnered with Cognizant Technology Solutions on a design project for a semester-long elective course called UX Design Tools. The intent was broad in its inception: identify emergent opportunities where technology will play a significant role in people's interactions and experiences. What is the future of physical space? How are advancements in IoT, augmented reality, and telematics influencing how we experience environments?

Students were asked to anchor their problem solving in evolving human needs and to understand the role technology plays. Cognizant's human-centered development approach relies primarily on ethnographic inquiry. This evidenced through integrating their anthropologists from acquired firm Idea Couture, and associates from strategic partner ReD Associates. The interdisciplinary majors from upper-level undergraduate to graduate level students learned to use and create multi-method research approaches to identify unique opportunities.

Seven teams created future scenarios with newly developed physical product designs, digital interfaces, and new service strategies utilizing various technologies. Three case studies highlight a trio of observed emotional themes in relation to how people utilize technology to benefit their daily life or work: self-election, introduction-exchange, and co-dependency.

This poster presentation will showcase three projects that will serve as examples of how industry and academia act as research and development entities; how to approach research as a fundamental tenet for innovation and design; and show how breadth and depth of interdisciplinary skills and experience is a necessity in an ever expanding climate of technology push.

Keywords: ethnographic research, future casting, design systems
Taming Technologies Role in the Future Through Design

Carnegie Mellon University's School of Design partnered with Cognizant Technology Solutions on a design project for a semester-long elective course called UX Design Tools. The intent was broad in its inception: identify emergent opportunities where technology will play a significant role in people's interactions and experiences. What is the future of physical space? How are advancements in IoT, augmented reality, and telematics influencing how we experience environments?

This project’s premise is at the heart of today’s role of technology and how people will adopt and interact with the world. Currently, people are reliant on a range of personal technology products to being networked into a complex digital ecosystem connecting work, play, and everything in between. With logarithmic advances in computing power, artificial intelligence, new material technology and manufacturing options, design and designers are at the forefront of humanizing these tools and interactions.

What processes can be employed to leverage digital, material, and unimagined technologies? Discovering these possibilities and how technology may play an essential role to our new future is why ongoing investigations through contextual research is essential. And it is a necessary tool to mine the diverse range and depth of each business and industry sector’s opportunities. The possibilities to change and improve people’s everyday lives through starting with a human understanding versus technology an idea, opens greater possibilities for impact. And designers are trained to seek and see things through the lens of the user. Designers possess a unique set of abilities that generate new perspectives and unique opportunities by using behavioral research skills, analytical abilities, collaborative nature, and generative skill sets. They apply these methods and skills in both intangible and tangible building to propose and produce unrealized solutions.

In the perpetual march of exponential technological progress is important to note that this project’s approach purposefully started with observing and engaging people, as people and not as users. Human centered designing starts with a particular mindset. This mindset requires empathy and understanding at individual to societal levels. Being contextually aware and listening to other people’s experiences is the starting point and essence of qualitative research richness. We have seen prior examples of when man machine interfaces were not properly considered. Or when efficiency is prioritized over human needs and control is stripped from human operator. It is the study of people and their behaviors that is the core enabler of how latent opportunities are derived. This mindset and journey of discovery provides a map to natural and safe solutions to human machine interface - and ultimately ethical technology development centered on human needs.

Interdisciplinary Project Overview

Seven interdisciplinary teams with three students per team were organized in a 15-week elective course called UX Design Tools. The students ranged from junior, senior and graduate level students. Each team consisted of three members, comprised of at least two designers, a communication designer and an product designer. The third member included
computer science, human computer interaction, engineering, architecture, or humanities majors. The course is a longitudinal mixed method research project based studio. Significant emphasis is given to applying traditional behavioral research methods that are the basis for developing participatory, generative action tool methods.

Concurrent with the research processes, design teams used visual conceptual mapping and modeling to understand the problem space. Progressively in the process, design teams created low fidelity prototypes and/or generative tools to test and iterate with participants. Depending on the design opportunity, the teams designed physical and/or digital solutions. These designed artifacts act as assets for a future-state scenario that culminates into a final video sketch. Each team member has overlapping levels of experience, range and depth of skill, and some prior internship or professional experience. This paper highlights portions of the teams’ processes and artifacts created that lead to deeper human understanding and ultimately their product and service solutions.

Why is Carnegie Mellon University a strategic partner with Cognizant Technology Solutions? Cognizant is one of the world's leading professional services companies, transforming clients' business, operating and technology models for the digital era. Their industry-based, consultative approach helps clients envision, build and run more innovative and efficient businesses.

Headquartered in the U.S., Cognizant is ranked 230 on the Fortune 500 and is consistently listed among the most admired companies in the world. Their specialties include: Analytics & Information Management, Business Process Services, Intelligent Products & Services, CRM, SCM, IoT, Cloud, Intelligent Automation, Infrastructure Services, Quality Engineering & Assurance, Application Services, Enterprise Risk & Security, etc. As a large scale, multinational technology service provider of information technology, consulting, and business process outsourcing services, Cognizant is aimed at identifying and developing new solutions, services and strategies that change the way we experience the world and do business.

To be a continual leader in this highly competitive field, Cognizant focuses on being a partner for end-to-end digital transformation - believing a successful enterprise must understand the context in which they compete and invest in new business, operational and technology solutions. To commit significant investment towards transformation, Cognizant needs a robust understanding of the primary benefits and goals to the business and intended audiences. One of their means of staying at the leading edge is contextual research - a combination and series of ethnographic and longitudinal research uncovers problems or gaps through the investigation and process of human interaction and behaviors.

The primary Cognizant project lead for the course, Carly Burton, Global Director of Human Sciences Technologies, primed the project initiative with various scenarios spanning from the future of retail, transportation, communication, to how entire cities and infrastructure will be reimagined. As a proponent for human sciences and appropriate user centered design in a technology services company, Burton focuses on extracting insights from people to understand their contextual norms and behaviors and how their collective beliefs influence a system. Specifically, through the process of social study, Burton exposes unarticulated needs and
discovers historical experiences and critical pain points to design against. Overall the ethnographic methods are used an open-ended approach to research, so people speak to what matters most to them, sharing how they relate to the world.

Cognizant’s acquisition of innovation firm Idea Couture, and strategic partnership with ReD Associates, provided further exposure for the project teams to understand alternate methods of human inquiry. ReD Associates consultants, including Partner Mikkel Krenchel, gave guest lectures on how ethnography and behavioral research methods are a starting point for deeper understanding, analysis, and insights. They emphasized the value in framing questions around human phenomena and the sensitivity necessary to understand another culture and people. Paul Hartley, PhD, Executive Director, Institute for Human Futures, Sr. Resident Anthropologist from Idea Couture also participated later in the semester to review the project team concepts and proposed storylines. Hartley provided critique on the translation of human insights into the design solutions.

**Course Dynamics and Common Denominators**

Significant challenges occur when managing interdisciplinary teams. Concerns for enabling each member to utilize their own experiences and capabilities is paramount. One of the common denominators used to align teams was the design research process. The barrier to entry is relatively low for using observational methods such as AEIOU. The value and richness of the information becomes self-evident. This starting points provides a basis for framing the situation and next steps of research methods. When presented with the relatively broad scope of the project, teams devise research plans and tools that would give them an understanding of the subject area in question. Creativity in devising the research methods and protocols is becoming a significant role of studio-trained designers.

Designers naturally visualize and map the collective team’s participants’ current state. Working with the qualitative information in tangible forms such as images, quotes, maps allows for synchronous team analysis and synthesis. Outliers, significant aspects, pattern identification, and other notable results of the research occur during this fluid part of the process. Both instructor and client sponsor ensures the team members ask themselves critical and relevant questions that probe for latent needs and what is the norm.

The design research process builds on observed and recorded research. This traditional behavioral research becomes the basis for subsequent generative research methods and tools, where the project teams can gain additional insights that challenge and refine their design hypothesis. In essence, designers extract insights on human behaviors and then experiment with solutions they believe will drive the most value, and then take those ideas into a learning cycle. The generative learning cycles enable team members to build solutions that enhance and influence human experience.

When the project teams apply this process to the design brief, several topics immediately emerged on core changes facing the current infrastructure’s inability to cope with the rising and changing North American population needs. The final topics of each of the seven teams
included: augmented reality as an enabler for airport experiences, physical and digital props to create interconnected neighborhoods, the future of autonomous car ownership, multi-modal transportation in urban environments, helping expatriates meet new people, enabling ADHD students to succeed, and refining EMS processes and technology systems.

This paper will focus on three primary project team cases that best highlight how and why longitudinal and contextual research was essential to finding new opportunities. At a meta level, we found that these project teams, uncovered very special human emotions that became the driver of opportunity for combined technology and enhanced human interactions.

The three teams included: Compass, Time Management in Mixed Reality (inspired by aiding ADHD students); Fika, helping expatriates meet people to mutually share each other’s culture; and Claro, a connected EMR system built around each person affecting the care system. In retrospect, the journey through ethnographic, contextual research led the teams to identify interaction archetypes that we identified as: self-election, introduction-exchange, and co-dependency.

**Team Compass: Self-Election Behaviors and Interactions**

Compass team started simply by attempting to help students with mental disabilities. Several weeks of literature reviews and interviews with trained educators in special needs helped them further focus their project scope. The main qualifier to this course is that students have to have access to the targeted participants in order to administer first-person interviews and subsequent action research. This criteria ruled out a significant portion of mental health subjects due to Institutional Review Board regulations and course limitations. However, college students with Attention Deficit Hyperactivity Disorder (ADHD) self-identified and were willing participants in the project. The unique aspect of this participant group was that they in some form, conquered part of their own disorder. Their presence in a higher-education academic institution proved to themselves and others, that they can achieve goals regardless of their personal disabilities. The team focused their research process and methods on six, self-identified ADHD college students. One of the primary take aways that served to be a difficult challenge was that ADHD students all learn differently and there is no ‘best practice.’ A second mantra was simply stated: ‘being successful in school is a lot about getting sh*t done.’ Interviewing these students was incredibly value because they had already developed their own tools - self awareness, cognitive strategies, time management, and other methods of accomplishing short term tasks that built towards larger goals. With numerous organizational tools in both physical and digital forms, the team used these prior tools as a basis for mapping and understanding basic fundamentals and benefits of each one. Alternately, from the human perspective, they identified that productive people needed: flexibility, focus, and motivation. Contextually to ADHD college students, Flexibility meant the ability to manage or flex to a task dynamically and not build strict rules or timetables; Focus was the ability to be notified or shown relevant tasks in relation to their location and other task priorities; and Motivation was a personally relevant and perpetual way of showing progress and improvement.

The following images and illustrations will provide an overview of the research methods and processes this team employed to arrive at their mixed reality design solution. As with most
design thinking and design processes, there is a convergence, divergence flow to the process. The literature review and early interviews with educators led to a broad scoping of the potential situations surrounding mental learning disabilities. This is visually represented in Figure 1: Concept Mapping / Compass. Convergence to ADHD college level students is represented in Card Sorting Activity and learning about their current digital tools and strategies that go along with these tools.

**Concept Mapping**

Our initial direction focused on providing a solution for college students with mental disabilities. We dove into our problem space by exploring all of the opportunities and factors involved in the mental disabilities space. Focusing on social behavior, communication, awareness, help, and learning.

![Concept Mapping / Compass](image)

**Figure 1: Concept Mapping / Compass**

Figure 2: Exploring Existing Digital Learning Environments. At this moment in the research process, since the discussion was about technology, the team used provocations to elicit future ideas and scenarios where the participants could imagine themselves.
Figure 2: Exploring Existing Digital Learning Environments

Figure 3: Initial Provocations and Figure 4: Initial Provocations Participant Output show the exercise prompt and example responses. Interestingly, a moment of divergence occurred when the team analyzed and started mapping the responses from the ADHD participants. If the tools and techniques were so useful to this population, why couldn’t others benefit from them?

Additionally, many of the tools were not ADHD specific. So how were others using these tools and how are the different from the intended user group?
Initial Provocations

I sketched out several concepts using Augmented Reality. We presented these concepts to participants to gain initial reactions and feedback as to what features and concepts might be practical.

Figure 3: Initial Provocations

Figure 4: Initial Provocations Participant Output

Figure 5: Mapping (Divergence 2), Figure 6: Mapping: Control of user aspirations for a level of control through the day, and Figure 7: Control & Helpfulness mapping portrays the daily activities in relation to a simple four quadrant, with two semantic differential continuums (Control vs. No Control / Helpful vs. Harmful).
Mapping

We decided to broaden our user audience from just students with ADHD to all university students who struggle with time management and productivity. We used our previous findings and initial research to guide us in what to do next. We began by grouping key needs and values that our research participants had expressed. We discovered that the idea of control was extremely valuable to everyone we talked to. If users felt in control of their daily lives and were able to manipulate the way they plan and schedule, there was a greater sense of accomplishment and heightened emotion.

Mapping: Control

This mapping exercise helped us understand what positive aspirations users want to have control over (Green) and what negative everyday influences might get in the way (Red).
Control & Helpfulness

We then organized daily activities, moments, and distractions on a chart. This was useful in identifying where pain points might arise during a normal day.

Figure 7: Control & Helpfulness

Figure 8: Journey Mapping is a natural extension of visually organizing and presenting a typical day with the purpose of finding the ‘curve balls’ or incidents that would easily affect an ADHD student from their intended regimen.

Figure 8: Journey Mapping

Figure 9: Drawing it Out converged on the cognitive specifics of how the participants would currently plan their day. Figure 10: Dynamic Scheduling asked them to move slightly out of their comfort zone and to re-imagine and learn a new method shown in Figure 11: Bullet Journaling and Figure 12: Not a Hit, reaction.

Figure 9: Drawing it Out

Figure 10: Dynamic Scheduling

Figure 11: Bullet Journaling

Figure 12: Not a Hit, reaction
Drawing it Out

Kaleb instantly asked for a pen and paper and began to sketch out blocks that represented different events he had the following day. This method was no surprise to us, but some of the conversation that followed shed light as to why he prefers to draw it out. He mentioned that he tends to leave the sketched out paper on his desk and that the reason he writes down what he has to do is more about the ritual and thinking than using the actual paper to follow later in the day.

Dynamic Scheduling

We then asked him to draw out an ideal weekly calendar. We found Kaleb’s week outline very interesting. He drew out two main areas, one was a more standard weekly calendar graph, the other was a list bank. He explained that his concrete daily activities would always live on the weekly chart but his Todo’s would stay in a constantly changing bank. He can create and delete tasks and also be able to control where to place the “event blocks” in his daily routine. He explained that if he wasn’t able to complete one of the less important tasks, it would just automatically fill back into the todo bank.
Bullet Journaling

We then had him learn about a daily planning technique called Bullet Journaling, a customizable and forgiving organization system. It can be your to-do list, sketchbook, notebook, and diary, but most likely, it will be all of the above. We wanted to use this technique because it focuses on making more dynamic todo lists, using icons and symbols. (example on the right)

Figure 11: Bullet Journaling

Not a Hit

On the left is Koleab’s attempt at bullet journaling. His reactions were valuable, he mentioned that it would be hard to keep up with. He also typically likes to not put too much thought into each one of the things he has to do, with no concrete start or stop time.

Figure 12: Not a Hit

Figure 13: Workshop: Time & Productivity, Figure 14: The Activity, Figure 15: Insights are a Divergence that was necessary to test the team’s findings against a more universal population. Limited to six ADHD participants, the team needed to ensure a broad perspective was not lost by engaging 24 participants. This generative research method reinforced their initial
findings, but also helped galvanize specific themes and criteria for the design solution. Ironically, the divergence step, progressed to a convergence of design criteria.

Figure 13: Workshop: Time & Productivity

One thing our group was lacking was a larger number of research participants. Up until this activity we had only interviewed four students. Even though they were lengthy and insightful, we wanted to gather a larger perspective on the idea of time management and productivity and how it was being addressed on campus. We set up a table in a highly trafficked area of our university and offered free donuts for some thoughts. We had no idea donuts were in such high demand.

Figure 16-21: User Category responses are a synthesis of the current workshop but were seen in some shape or form from earlier interviews and research. This part of the process was transformative towards key Themes that defined the tangible design concept. Highlighted themes that were expressed included: Removing Stimuli, Self-reflection, Feedback, Peer Support, Rewards, Motivation, Dynamic Scheduling, Prioritization, Health, and Physical Space. In realistic terms, one product may not be able to address all of these inclusively. So, a subsequent re-Mapping of an intended user’s day was graphed to these high level themes to conceptualize which features and interactions may be best addressed with near-future technology. Figure 22: Mapping (of day to day Tasks and longer term Goals). Figure 23: Mapping (Tasks and Goal Relationships)
Environment / Mindfulness

Figure 16: User Category Themes, Environment/Mindfulness

More time to focus on what I want

This participant mentioned that he wanted the boring tasks to be done for him (even having someone to sleep for him) but he still wanted to do his class and project work.

Figure 17: User Category Themes, More time to focus on what I want

Social Support / Health

This participant mentioned that she was extremely organized and used Google Calendar frequently. She mentioned that she missed having an agenda like in her high school because there was a place to reflect on what she did on the weekend. Her agenda also served as her diary, something Google Calendar doesn’t facilitate.

Figure 18: User Category Themes, Social Support/Health
Figure 19: User Category Themes, Goals

Goals
This participant keeps three physical sticky notes on her computer and uses them for different lists. She has also begun using her stylus to write notes on her mobile phone, which she then screenshots.

Figure 20: User Category Themes, Dynamic Scheduling

Dynamic Scheduling / Health / Eisenhower Matrix
This participant basically gave us the solution. He shared the Eisenhower Matrix: tasks are evaluated using the criteria important/unimportant and urgent/not urgent, and then placed in according quadrants. He also created a visual very similar to our prior participant, kaleb.
Mapping

We then went back to mapping out a person’s day. This time we focused on a circular timeline with a rippling effect. The most inner circle illustrates the day to day tasks the person encounters. The blue notes describe larger long term goals or motivations the user might have. Their placement linearly stems from the smaller daily tasks.

Subsequent Figures are a focus and convergence towards a tangible mixed reality product design concept. Figure 24: Mapping of Design Concept Timeline Moment Features. An online survey
was distributed and in a short response time of less than three days, 25 respondents replied to what type of AI, voice operated technology they used. Other questions revolved around familiarity and use of digital assistants or technology. This concurrent research enabled confidence in certain design proposals to use voice and gesture technology. Figure 25: Artificial Intelligence Tools You Use Chart.

Figure 24: Mapping of Design Concept Timeline Moment Features

Select the Artificial Intelligence (AI) tools that you use. (25 responses)

Figure 25: Artificial Intelligence Tools You Use Chart
Figure 26 through Figure 36 are the convergence of design ideas based directly from the extensive longitudinal multi-method research approaches. This point in the design process is quite fluid as the team is completely aligned in purpose because of their understanding of the user group’s needs and mindset. Design decisions are relatively easy to determine because the team has a repertoire of knowledge and real life scenarios to draw upon. A rigorous, self-built research process allows confidence in design shape, form, and color based on the higher level themes and concepts.

Figure 26: Interface menu concept
Figure 27: Interface concept wrist arrangement and hierarchy

Figure 28: Interface concept daily time screen shots
Figure 29: UX/IxD User Flow

Figure 30: Interface To-do List Concept
Figure 31: Mixed reality cross-section placement and interface diagram

Figure 32: Mixed Reality screen examples
Figure 33: Interface Menu Options

Figure 34: In-AR glasses view concept
Each team develops a video sketch demonstrating the future reality intended by the product, system, and/or service. Team compass video is necessary to view the extent of the new product interface and application of mixed augmented reality for enabling ADHD users. The true testament of this project, is that the design concept they proposed could be transferred to the general population, alternate industries, and other environments to be universally helpful.
Team Compass: Katherine Apostolou, Elaine Choi, Gabriel Mitchell

This is relatively typical of the range and depth of research processes conducted in the UX Design Course Studio. However each team and project is highly unique in relation to the subject matter chosen, participants, and overall context. This short paper will only describe the highlights of the other two project examples to show the differences in high level conceptual human behavior categorizations.

Team Fika: Introduction-Exchange

The initial problem space this team was interested in helping started with immigrant refugees. Similar to Team Compass and the remit of the course, it is necessary to have first-person access and interaction with the primary constituents you are trying to understand and ultimately help. After several weeks of attempting to gain access to this at-risk population, it was deemed too difficult with the resources available. The team pivoted to exploring the practical and emotional needs of international students and scholars. As a newcomers, they saw potential in individuals being and becoming part of a dynamic community. Some of the early literature research on refugees paralleled similar findings of loneliness and overcoming initial social barriers. It was noted that there can be hundreds or thousands of people in your immediate vicinity, but an overwhelming feeling of loneliness still prevails. This incredibly human and emotional aspect of the project was the focus of the future solution; a significant amount of existing tools and processes are available to address practical logistics of moving and initial transition. The Fika converged their primary problem statement as: How can we help international students meet people who are willing to share culture and conversation? The follow up and deeper question to their goals was: How can we help newcomers meet people and get to know people who are willing to share their culture and community, and form deeper connections?

Capitalizing on various other tools not directly related to transitioning expatriates into a community was investigated. Divergent research on dating apps, personality quizzes, corporate or employee on-boarding processes, and many other resources were reviewed. Design criteria converged to particular elements that would enable a low-barrier to entry for an in-person event and allow people to be themselves while connecting related interests. Three desired criteria in combination showed the greatest promise at initiating personal connections: proximity, spontaneity, and shared interests. The term fika, is a Swedish institution for sharing coffee or taking a break from the workplace while meeting with colleagues and friends. This team saw the newcomers as growing the cultural richness and intelligence of the city by bridging the segmented gaps. One of their primary research source was partnering with Pittsburgh Regional International Student Ministry, PRISM organizers. One of the primary means of getting expatriates comfortable in their new environment is through conversational English. Their mission was very much in line with team Fika’s goals. Through various converging and diverging research methods, 10 interviews, interviews and research collaboration with three PRISM organizers, surveys with 32 respondents, and literature reviews led to several
generative research methods. The generative make tool was introduced at a PRISM dinner in a group setting for four people. The following figures represent the research method and tools to create a conversation with the researchers and themselves. Figure 37: Example Generative Research Self-List of Transition, Figure 38: Time Relation to Transition, Figure 39: Open-ended question response.

Figure 37: Example Generative Research Self-List of Transition
First week
- finding friends
- bus routes
- weather
- closures

First month
- food taste
- loneliness
- English

What was the hardest part about adjusting to Pittsburgh/USA? How did you overcome that difficulty?

Personally, loneliness was the most difficult issue I had in the USA initially for 9 months. I liked to make relationships, but I didn’t know how to do it.

Figure 38: Time Relation to Transition

Figure 39: Open-ended question response
From this research, the team visualized the common points made by this generative research and prior behavioral research methods. A form of self-reflective map acted as a process journey map shown in Figure 40: Process Journey Map. The design criteria and human centered design had come full circle and was quite self-evident in this project. The convergence and synthesis showed that: meeting people and overcoming loneliness are the hardest parts; people build strongest bonds through shared interests, exploring a city enables a person to feel comfortable and gain a sense of belonging. However, Fika’s and the class remit was to imagine what type of technology would improve and enable higher level goals to be accomplished. The team imagined technology as a starting point for solving some of the initial hurdles of the transition journey, but wisely not an entire, competing social app or system. By developing a specific app and video capture device for people and organizations dedicated to this type of work, Team Fika proposed using technology as the ice breaker, rather than a perpetual social connection tool. Figure 41: Example App and Key Features describe the simplicity of the technology. This simplicity was intended to be the digital handshake or introduction. The subsequent in-person meeting would then allow the primary topics of building bonds through shared interests, exploring the city in relation to a self-elected interests, and beginning to overcome seemingly high barriers to connecting with people in meaningful ways.

Figure 40: Process Journey Map
Users can see fikas around them, viewing 360 video of events, click I’m attending, and the host can find them through AR to greet them and introduce them. You can add people you meet for further more meaningful interactions.
Team Claro: Co-Dependency

Team Claro began with a general interest in how AR, IoT, and telematics technologies could impact the medical industry. After exploring several different problems spaces within the medical area, they saw significant opportunities in the Emergency Medical Service first-responder system. This case shows why extensive interviews with the range of stakeholders was necessary. Figure 42: Stakeholder Map provides a glimpse into the complexity of the system and how many people are part of the situation. However, as the project research continued, they saw each connection or relationship between the stakeholders as moments for improvement. These improvements may be creating the right link or connection; another improvement may be decreasing the time gap between connection; but one of the most main areas for opportunity seemed to be the fidelity of information and communication. Figure 43: Concept Map of EMR Connection shows the overall current state of Emergency Medical Responder, EMR relationships. Team Claro stated their opportunity statement as: We aim to enable a person with an emergency to connect with the emergency service system faster and more effectively, and enable a better connection with the responder for improved assistance. Primary research participants included Emergency Management coordinator, Patient Care coordinator for medics, city and campus police, EMS physician, EMS researcher, 911 dispatch, campus environmental health and safety coordinators, two local EMS units, and several emergency callers.
Through the research, multiple visual representations were essential to understand the various complexities and dynamics. Two generative research tools asking first-responders and 911 callers to map their experience, culminated into the following converging diagrams.
Figure 44: Refined Stakeholder Map and Figure 45: Timeline Map portrays the multitude of actors involved. And once the detail of the relationships and interactions were discerned, a scenario of what is occurring is visualized in Figure 46: 01 Lack of Accurate Information Stage, Figure 47: 02 Dependent Transfer Points Stage, and Figure 48: 03 Delays Stage.
01 Lack of accurate information
Barriers limit the quality of information exchange

02 Dependent transfer points
Critical information isn’t centrally accessible and must be passed along several times
From viewing these illustrations and synthesizing all of the stakeholder responses, the team had to reimagine the human and technological options available. This high level concept is represented in Figure 49: Claro Concept Map Solution. The key insights from the ethnographic research drives the solution, the overall system architecture, and end-product interactions.

Ethnographic research attempts to glimpse into a particular segment of a population’s culture - be it professional, family, education or some other environment or context. It is the designer’s role and responsibility to discern the unseen and unsaid through creative processes and methods. Figure 50: Team Claro Synthesis shows a room and space dedicated to understanding this particular problem space. A space requiring photographs of people in situ, quotes and saying of the stakeholders transcribed and place and replaced according to the analysis and team discussions, re-worked conceptual maps and diagrams, and other data that takes up physical space so that a team can be literally on the same page at the same time to discuss, argue, and fight for the constituents they chose to help.
Figure 49: Claro Concept Map Solution

Synthesis

When we generated our key insights from the affinity map, they ended up on this wall and were turned into statements and models based on research.

Conclusion

The three project team solutions provide examples of how human sciences and appropriate user centered design delivers insights on people and their collective emotions to guide a system. By understanding the contextual norms and behaviors of participants, each group was able to focus on core unmet needs and artfully design solutions that connect to existing behaviors while also foster new ones.

Specifically for Team Compass, the research guided the team to develop a personal, wearable and AR device that would be part of a larger personal life management system. The priority for design is pointed directly towards a single, primary individual. Similar to a health fitness tracking device like a fitbit, this device would be categorized as a self-election for personal improvement. Whereas team Fika’s system purpose is to build a method for connecting people to people through simple and low-barrier of entry interface that capitalizes on physical proximity. The priority design in facilitating a connection of people and how they relate to the world. Lastly, team Claro purpose is a professional, critical emergency system that connects all the relevant parties through the highest communication fidelity possible. The priority design creating security, awareness and better connection to care.

Overall, uncovering the human emotions became a driver for each team’s opportunity so the technology solutions enhanced human behavior and interactions.
Authors Biographies

**Wayne C. Chung** is an Associate Professor and Product Design Program Chair in the School of Design. Chung's research and work spans medical systems and devices, robot design, consumer, and industrial products. He teaches first-year Design Studio, Advanced ID studio: Product and Systems, How Things are Made, Applied Research Methods, UX Design Tools, and co-teaches Bio Medical Engineering.

Chung utilizes design research methods and develops new processes to understand the person in context. This essential approach enables insight and appropriate innovation within a world of complexity. Material, aesthetics, fit, and other user experience variables can only be designed once the problem is appropriately framed and considered relative to the human, artifact, and environment context.

Chung holds a BFA with Honors in Industrial Design with a minor in Business Management from Carnegie Mellon University and a Masters of Industrial Design from the University of the Arts.

**Carly Burton** is a design research and strategy consultant. Working at the intersection of human sciences and technologies, she brings an empathic, curious, critical mindset to understanding people and developing new solutions and strategies. She is particularly interested in shaping new protocols and practices as it relates to the design, development and application of Artificial Intelligence and Intelligent Products. In her role, she is also involved in growing Cognizant’s Digital practice, shaping services, capabilities, and delivery across its global network.

Prior to moving into this role, Carly was the Global Experience Strategy Director responsible for the global Collaboratory experience and network. During this time, she also worked on digital transformation engagements with clients, leading multi-disciplinary teams on the identification and implementation of digital strategies. She was also previously the N.A. Director, Product Realization for Cognizant Digital Works focused on bringing products from idea-to-market. In this role, she managed and lead the design process for mulit-disciplinary teams and was responsible for insights, foresight and product requirements definition.
Writing Into the Unknown: Speculative, Arts-Based Writing as Creative Composition and Design Research Method

Vittoria Daiello  University of Cincinnati, Associate Professor, vittoria.daiello@uc.edu

Abstract

How do arts-based writing endeavors catalyze generative thinking and support research development in design students’ thesis endeavors? This paper offers reflections from an industrial design masters student, a graphic design masters student, and their arts education professor in a School of Design at a Research I institution. Informed by theoretical and historical contexts of the design discipline and perspectives from composition studies and fine arts practice, we explore the potential of arts-based writing as an evocative, speculative tool and a distinctive form of reflective practice for the development of graduate design research. We suggest that arts-based writing’s iterative process, dialogic engagement, and speculative approach to knowledge-construction provide critical, reflective structures for working through uncertainties and thus are uniquely responsive to the evolving epistemologies of the transdisciplinary university. Three focal questions guide this reflection: What is arts-based writing? What role does arts-based writing play in students’ design research endeavors? How can arts-based writing practices support the growth of speculative and pragmatic design research?

Keywords: arts-based writing; art education; reflective practice; design thinking; design research; transdisciplinary

Art is not a world, but a knowing of the world. Art prepares us. ~Muriel Rukeyser

How do arts-based writing endeavors catalyze generative thinking and support research development in design students’ thesis endeavors? Two masters of design students and their instructor respond to this question with analytic reflections on the arts-based writing methods used in developing the students’ design thesis projects. Sharing evocative glimpses of the students’ arts-based writing processes along with their reflections on this work, we seek to create a space of speculative discourse about how writing might be taught and perhaps (re)conceptualized in design education contexts.

The overarching goal of this paper is to explore and consider how writing activities emerging through/around arts processes occurring in a graduate-level, transdisciplinary writing course stimulated the development of students’ design research. To this end, three focal questions structure the paper: What is arts-based writing? What role does arts-based writing play in students’ design research endeavors? How can arts-based writing practices
support the growth of speculative and pragmatic design research?

In responding to these questions, we first define the concept of arts-based research writing and establish its pedagogical and practical relevance in the development of design research. Next, we provide exemplars of the students’ arts-based writing and share insights that resulted from their composing process. The paper concludes with a discussion of the unique affordances of arts-based writing methods and the potential they hold for engaging student researchers in sustained critical inquiry and reflective practices that lead to robust awareness and complex comprehension of wicked design problems (Marback, 2009; Leverenz, 2014).

The arts-based writing examined in this paper originated in The Art of Words: Writing Visual Culture, a graduate-level course offered within a School of Art at a research-intensive university. A focal aim of the Art of Words course is to facilitate the development of a reflexive, critical composing process that builds from students’ studio practices and research interests. The course melds art theory and practice into a seminar-workshop. In this environment, students experiment with form and content of written expressions through the creation of artifacts and texts and through engagement in dialogues about the artistic, conceptual, disciplinary, and political contexts of writing and communication. Arts-based writing processes provide a structure of iterative experimentation that strengthens the articulation and representation of complex phenomena in students’ research projects and studio practices.

Literature Review

Our consideration of arts-based writing unfolds within current, multidisciplinary discourses on research methodologies occurring throughout design, fine arts, and art education, and among scholars of arts-based methods (Bresler, 2013; Eisner, 2008; Cole & Knowles, 2008; Leavy, 2015) and qualitative research more broadly (Guba & Lincoln, 2005). Another strand of discourse is contributed by the composition studies movements of writing to learn and writing across the curriculum, bringing attention to the pedagogical use of writing as a disciplinary learning tool (Thaiss & Zawacki, 1996). An evolution of writing theory and practice through the vital influences of critical race theory, critical literacy, postcolonial and indigenous methodologies (Denzin, Lincoln, & Smith, 2008; Madison, 2005) further shape the project of critical reflexivity embedded in arts-based writing methods.

Engaging discussion of arts-based writing methods within the context of design studies is undertaken with equal measures of optimism and caution. Ken Friedman’s warning about the haste with which design theories rise and fall provides a necessary dose of skepticism (2008) for any researcher in any discipline. We find support in Friedman’s affirmations of documentation and its role in making tacit knowledge visible toward the eventual construction of explicit knowledge and theory. Yet at the same time, we acknowledge the necessity of making room for “research whose contribution to knowledge cannot be stated fully or precisely by the researcher,” knowing that “some contributions are necessarily generative,
providing a point of departure for others” (Rust, 2007, p. 75). Within the push and pull of debates that contribute to the design discipline’s vibrant criticality, optimism, and pragmatism, we find nodes and intersections where the concept of arts-based writing offers value as a critical, reflective practice (Bayazit, 2004; Kelly, 2004). We strive to generate documentation-data that could potentially translate tacit knowing into explicit knowledge and theory, yet we also embrace speculative, arts-based processes of writing into the unknown.

Research Methods

As an interpretive study of two individual thesis projects and the process of their development, the overarching goal of this paper is to describe, explore and reflect upon a particular phenomenon rather than produce generalizable results. This exploratory and descriptive approach is appropriate when observing a phenomenon in a real-life context for the purpose of generating an holistic account of its significant characteristics (Yin, 2003). Therefore, rather than seeking clearly defined outcomes, this essay aims instead to build a layer of reflective practice evidence (Harper, 2008) within which the role of arts-based writing processes in design research pedagogy can be deeply considered, studied, and potentially integrated into existing pedagogical methods for mentoring design research.

Writing as a Form of Inquiry

Sociologist Laurel Richardson’s (2003) research of writing as a form of inquiry establishes a methodological foundation for this study. Taking the perspective that human language is a site of contestation, invention, and action, we concur with Richardson’s assertion that a multitude of discourses “divide up the world and give it meaning in ways that are not reducible to one another” (p. 508). The fluidity and infinity of language, of writing, pulls us into a space of allatoniceness (Berthoff, 1981) where the plentitude and pliability of language become a rich resource. As a speculative tool and medium of expression, writing is a rich material for thinking with and through problems. For students in the course, writing’s immaterial materiality not only catalyzed meaning(s), releasing them from containment, it also functioned as “the very hinges of thought” (Richards, 1959, p. 24). As a focal object of this study as well as a method of inquiry used in each of the thesis projects, arts-based writing as inquiry creates sites of colliding and interpenetrating discourses. By facilitating opportunities for discourses to bump up against one another, unravel and even recombine to create new discourses, we experience how writing can be a conveyer of communication as well as a catalyst of transdisciplinary dialogues.

Sample

Two thesis projects created between September, 2016 and May, 2017 by Davida and Olivia, co-authors of this paper, provide focal data in this case. Reflections on these projects emerged from open-ended conversations among the participant-authors within ongoing explorations of the writing processes and artifacts that emerged during the course. Because this inquiry is concerned with expanding and enriching the understanding of writing occurring
Defining Arts-based Writing

The phrase “arts-based writing” emerged by necessity to identify the burgeoning, hybrid art and writing endeavors that developed around the curriculum in The Art of Words: Writing Visual Culture, a graduate-level writing course offered in a College of Design, Architecture, Art, and Planning at a Research I institution (Stout & Daiello, 2018). As a bricolage wrought from the goals, methods, and outcomes of arts-based research (Cole & Knowles Leavy, 2015), Schön’s (1983) theories of reflective practice, and Elbow’s (1973, 1998) low-stakes writing methods, the phenomenon of arts-based writing fundamentally emphasizes an iterative development of dynamic relationships among thought, expression, reflection, and action.

Embracing writing as a form of inquiry (Richardson, 2003), as artistry (Goldsmith, 2011), and as a poetics of practice (Ruekeyser, 1996; Sheppard, 2008), arts-based writing employs reflexivity and artifact-making as sensitized tools that guide the composition of meaning across (and through) expressive practices. Integrating the aims and qualities of conventional composition methods (Berthoff, 1983; Carter, 2007), phenomenological attunement (Merleau-Ponty, 1989), and the disciplined, imaginative, and generative qualities of arts practice in research (Stout & Daiello, 2018), arts-based writing not only functions as a tool of research inquiry (Richardson, 2003) it also serves as a methodology steeped in the material processes of art.

The arts-based writing processes experienced in the Art of Words course are transferable to other contexts and other uses. The art and writing methods employ familiar pedagogical tools from fine arts, composition studies, and writing across the curriculum contextualized within a qualitative research setting. Iterative, low-stakes assignments include consistent documentation of and reflection on process (workshopping with peers; multiple drafts and revisions, journaling, critiques); experimentation with materials, forms and purposes of expression (thumbnail sketches, mock-ups; critical analysis); and, research methods (observation and documentation; production of reflexive narratives; recursive analyses to identify themes and patterns). Key to arts-based writing is an emphasis on the development of a personal research methodology that both pursues and questions the representation of tacit knowing through sustained critical consciousness about the contingencies of the known and unknown (Harper, 2008, p. 165). These processes are not only applicable across disciplines, they are also scholarly habits that support the production of, and reflection upon, data through careful, critical methods sustained throughout the duration of a project.

Iterative writing experiments inspired by Peter Elbow’s concept of low-stakes writing (composition assignments characterized by their frequency and informality) were employed...
throughout the course, strengthening the articulation and representation of complex phenomena in students’ research projects. Often ungraded, a low-stakes writing assignment is designed to compel students to “regularly spend time reflecting in written language on what they are learning from discussions, readings, lectures, and their own thinking” (Elbow, 2000, p. 351). Writing Negative Space, an Art of Words low-stakes writing activity inspired by Rachel Whiteread (an artist who makes solid casts of the empty spaces existing around and within objects) prompted students to create narratives about places unrelated to their research topic. In fact, most of the low-stakes writing projects assigned in the course had no overt relationship to the students’ topics. The point of the activity wasn’t to produce written material for the thesis but to give students opportunities to experience the process of exploring and crafting ideas through writing and other materials. The artifacts and texts that resulted from the low-stakes prompts were shared and discussed in class, sometimes leading to thought-provoking conversations about the research topic, other times simply generating a steady stream of interesting material that, when later examined with a critical eye for patterns and themes, often generated valuable insights.

Composing research writing in this way has much in common with Tim Brown’s (2009) definition of design thinking: multiplying options to create choices.

Low-stakes writing and experimentation with art processes changed the pacing and focus of students’ work, allowing time and space for attending to details that otherwise might go unnoticed. By remaining immersed in the fuzzy front end of a topic, the students developed a greater tolerance for uncertainty and not knowing. Producing texts and artifacts that could potentially communicate these nebulous explorations challenged the students to take risks in their work, to trust in the tacit and evocative (Igweonu, Fagence, Petch, & Davies, 2011). In turn, they developed more sensitized awarenesses of the affordances and limitations of expression, perception, and action. Heightened attentiveness to an audience’s role in influencing expression and affirming ideas followed naturally. In short, a sustained practice of pushing and stretching ideas into communicable forms, or striving to understand and respond to the expressions of others necessitated a distinctive kind of design thinking—design as a poetics of process that bears witness to “vividly competing ideas about what it means to be human” (Buchanan, 1995, p. 55-56). In this way, arts-based writing in the Art of Words course provided a foundation of poetic, critical consciousness that advanced students’ abilities to use writing more sensitively and strategically in their work as designers and researchers.

Arts-based writing, in sum, is a productive, reflective practice that stimulates the development of diverse artifacts and divergent paths of thought while expanding a researcher’s capacity for working within uncertainties and learning from sites of precarity. In agreement with composition theorist Paul Lynch’s (2012) expansive perspective on composition, we see value in “making writing “messier and baggier…more open to complexity and even confusion” knowing that “what we lose in precision…we will make up for in inclusion; what we lose in focus, we will make up for in richness” (p. 465). Viewed in this way, arts-based writing offers designers and arts practitioners more pathways for seeking and affirming new worlds, identifying new ways of thinking, seizing sensitized nodes of awareness, and pursuing accelerating complexities.
Reflection on Arts-based Writing in Practice

The arts-based writing artifacts and texts created by Olivia and Davida provide a view of the holistic, expansive dialogues among self-other-world that grow within and around research projects. Although the objects that emerged from their arts-based writing practices were not intended for an art exhibition, they were nonetheless tangible, viewable, analyzable displays of sustained conversations with wicked design problems. Bringing the elusive qualities of thought into material form can be particularly useful at the outset of a project. In the initial stages, before a clear thesis trajectory is identified, novice researchers can feel flooded and even paralyzed by the allatonceness (Berthoff, 1981) and endless possibilities of a topic. As Davida confirms below, deciding what to pay attention to or disregard can be exceedingly difficult for a new researcher. Pressured to define a research topic quickly and decisively, students often disregard experimental pathways choosing instead to pursue ideas likely to yield consequential results.

Following Roland Barthes’ (1992) philosophy that the assumed “inconsequentialities” of a situation can be a potential gateway, a sensuous text born of the light of a landscape or the languor of a day, Olivia’s arts-based writing experimentation led her to a research portal of a surprising form: a cantaloupe’s skin (Figure 4). Deeply inscribed with a poem, the fragrant, textured surface of the fruit offered up subtleties about subjectivity, presence, and interaction that might have been lost to the “coarse filter” of academic methodologies (Barthes, 1992, p. 8).

Likewise, reflection on the proliferation of layers in Davida’s research journal (layered papers of varying thicknesses, layered mark-making practices atop pleated pages) provide glimpses into her experiments with narrative multiplicity. Grappling in her journal with the complex relationship of identity and trust-building among pregnant teens and social service workers, these layered texts are a precursor to the empathy sliders tool eventually proposed in her research. In short, the phenomenological materiality of arts-based writing creates evocative data that have the potential to shift inconsequential qualities of a situation into revelatory focus.

In the examples below, Olivia and Davida reflect upon the entwinement of writing, thinking, and design practices in their research projects. While their arts-based writing methods generated different pathways of insight, both gained greater awareness of how their own methods of writing and patterns of expression formed a dialogue with the world—and that this dialogic relationship is a sensitized research tool—a kind of divining rod—with the potential to reveal contours of tacit knowledge.

Davida

While there are few rules within design regarding how to arrive at a final solution, there is an implied criterion of expected modes of discovery and communication. As an industrial designer I have seen a forward momentum where product designers are increasingly juxtaposed with engineers, quality control management and marketers within the workforce. In this corporate-focused, industrial design culture where validation and exactness are expected of proposed ideas and concepts, low-stakes writing methods are a surprising
paragon of innovation that bring both disruption and clarity to the interplay of research and problem-solving.

My Master’s thesis developed tangible design tools that awaken empathy and trust between low-income, African-American, single mothers and their social service workers. However, early-on I found it difficult to translate copious amounts of literature research and consumer narratives toward the development of a pragmatic and actionable product solution. Arts-based writing provided a space of possibility that allowed the curiosity of my mind to wrestle with the systematic dilemmas revealed in research, insights from my study’s participants, and my own personal creativity on an equalizing plane. In this space of experimentation, abstract thought could be visualized and manipulated alongside aesthetic conceptualization through textual means. My thoughts, captured in the midst of becoming meaningful form, were tangible modes of creative insight that could be further ideated and visualized using traditional design methods. The production of these thought-artifacts allowed for end-results which could be carefully traced back to their origins to be directly validated by the research or insights from which they emerged.

It is unfortunate that the idea of using writing as a design tool had never occurred to me. Prior to the Art of Words course I relegated writing only as the medium through which a design could be explained. Thus writing usually occurred after all the design efforts had concluded, functioning to justify the design process or explain the product in order to placate skeptics. These post-process writings were seldom personally meaningful—a mere garnish to conceptualization and production of the design. Conversely, through art-based writing, my textual explorations quickly become meaningful with my research notebook for the class taking the form of a visual journal (Figure 1) used to catalyze my thoughts as I pursued the development of a design intervention.

Figure 1: Personal Writing journal from Art of Words (2016)
As an example, in one activity in the Art of Words course, I experimented with the layered complexities of social stigmas surrounding teenage pregnancy as opposed to generic motherhood and childhood. Through surveys, I collected terms and phrases that people associated with childhood, motherhood and teen pregnancy. I assembled imagery of these words into collages (Figure 2) and juxtaposed these with illustrations from an artist based on perceptions of childhood. The assembled series (Figure 3) shows the progressive attitude shift of society from childhood (on the left) toward motherhood (on the right) with a figurative “bridge” (middle) representing language associated with the perceived, unstable state of teenage motherhood. Visualizing the theoretical thoughtscape of Americans towards young motherhood helped me deeply connect the displacement of identity within the social phenomena of teen motherhood and was invaluable in propelling me towards a final product solution that was tailored towards bridging trust gaps between an insecure, young mother and her social service provider.

Figure 2: Tapestries of Motherhood (2 of 4) (2016-2017)
Art-based writing is potent creative discovery. I believe my familiarity with the iterative process of discovery as a designer enabled me to ease in and out of arts-based inquiry seamlessly—discovering to write, writing to discover. No longer just a complement to my creative process, art-based inquiry continues to push me towards deeper and more directed discovery even after the course ended and I continue research on my thesis topic.

Olivia

While researching my Master’s thesis topic of haptic (hand-driven) reflection in graphic design education last year I was afforded the opportunity to navigate the ambiguous nebula through the writing exercises, texts, and mentorship of the Art of Words course. Chapters and excerpts from selected authors and philosophers sparked a dialogue that manifested into written reflections inspired by the power of writing’s tactility, the beguile of embodied meaning-making, and drawn expressions. Throughout the semester, I engaged in a metaphorical dialogue with the ideas of philosophers Deleuze and Guattari (1987). Deleuze and Guattari’s concepts of desire, the becoming-self, and haecceity were provocations that challenged me to reflect on my writing process and, in time, persuaded me to conceptualize my writing and design research as a relational space—a locus where the impossibilities of ever-expressing my ideas completely or perfectly revealed surprising new forms of creative possibility: a cantaloupe inscribed, a mirrored text, and a tiny package of drawings, among others. I strove to express the Deleuzoguattarian ideas of embracing the transiency of living (the becoming-self), desire as a “process of increasing expansion, connection and creation” (Colebrook, 2002, p. xxii) and haecceity (the inherent thisness of an individual/thing) conceptually, and through reflection.

Exercising my characteristic pre-crastination and introspective penchants, I strategically crafted the idea behind each of the creative pieces in the Art of Words course. This work classifies as conceptual, for the planning and process were decided upon before production. But unlike conceptual art, I did not consider the actual making of these artifacts completely perfunctory—the execution of the work was just as much a thoughtful, embodied process as was the front end.
The articulative projects from the Art of Words also represent the virtually limitless possibilities of haptic writing. With the poem-inscribed cantaloupe (Figure 4), for example, I was writing to explore a process. The moon poem engraving symbolizes my Deleuze and Guattari-inspired articulation of desire, the moon’s cratered surface signifying a sense of lack. The conscious selection of a three-dimensional form gave the poem’s words a whole other realm of meaning. My intention in carving the poem into the surface was to make its interpretation interactive—both in rotating the sphere to read the narrative and in running your fingers over the words, filling the trenches of letterforms, making the void whole with your presence. Aliteral reflection, the epistolary articulation from an Art of Words class excursion to the local Contemporary Arts Center (Figure 5) represents another manifestation of a dialogue with an experience, and a defamiliarization of the familiar and interloping into the unknown. Again, as with the cantaloupe inscribed, the letter’s decryption is interactive—in order to interpret its content fluently the reader needs to hold up the page before a mirror, and it is there in the reflection that the message is cast. The moon engraving poem also ties into the designer’s process of thinking and of generating ideas. The poem itself and its manifestation on the cratered fruit validates those twists and turns, the risks designers take off the beaten path that help create better ideas. For, sometimes these side trips and excursions that we make are the most productive—but the value of the journey is never realized until it has been actively reflected upon.

From ideating through sketches and scrawls on paper, to the sensorial challenge of inscribing the melon with my poem, to ciphering the experience through written reflection, each phase of the process-journey was inherently embodied. Being that it was handwritten and placed on a three-dimensional fruit, the melon-moon poem forced a unique synthesis of thought and presence in the moment that resulted in a deliberateness of action and sensory stimulus that often is missing from routine, repetitious graphic design tasks. The moon engraving poem and other activities from Art of Words speak to what one does as a person in their lived experience, how these experiences intersect with what one does in the professional setting, and how the spectrum of these activities informs professional output.

Discussion

Operating from the premise that design is an inherently social activity that arises from, engages critically with, and acts upon the sociocultural contexts within which it is situated (Barzdell & Barzdell, 2013; Richter & Allert, 2017), a critical, reflexive design approach that is exercised through the practice of writing provides opportunities to explore the dialogic, speculative (Dunne & Raby, 2013), and precarious nature of meaning-making. Instead of proceeding from the assumption that meanings are immutable and truths are verifiable, a critical, reflexive practice of composition such as arts-based writing opens up a conversation among people, texts, materials, and meanings.

Art and design students who establish an arts-based, critical, reflective writing practice in relation to their design research create the conditions for the development of an internally persuasive discourse that brings greater confidence in, and clarity of expression of ideas. Borg (2004) draws from Bakhtinian theory to differentiate an internally persuasive discourse which is mutable and an authoritative discourse, which is static. Explaining that “(t)he words of another can be either authoritative – recited by heart – or internally persuasive – retold in
one’s own words,” Borg offers that an internally persuasive discourse can effect a “more profound relationship” between an artist and the “discourse of another” (Borg, 2004, p. 195). Specifically, an internally persuasive discourse involves a transformation of subjectivity. That is, by incorporating the discourse of the other (a theory paradigm, or an expert’s knowledge, for example) into one’s own lifeworld schema, the discourse and the subject themselves are transformed through the revisions and negotiations of meaning that occur in the process. For Olivia and Davida, arts-based writing and the creative artifacts that emerged in the process, were agents of speculative dialogue that shaped and affirmed an internally persuasive discourse in each of their research projects.

Arts-based writing practices, such as the low-stakes, hybrid art/writing activities used in the *Art of Words* course are uniquely responsive to the evolving epistemologies of the transdisciplinary university. Specifically, by pairing the processes of writing and experimentations with materials toward the expression of an idea, and employing these processes within an iterative, reflective practice, the messiness and uncertainty of human expression and communication are foregrounded. By bringing the precarity of communication into the foreground, and by producing tangible evidence of the multiple ways an idea can be expressed, received, understood, and valued, we expand the possibilities for designers, researchers, stakeholders to “see” and “hear” one another. There are myriad languages through which we might know and understand one another. For example, as artist Lynda Barry observes: “Drawing is a language. It’s hard to understand what that really means until you’ve ‘spoken’ and ‘listened’ to it enough in a reliable, regular way” (in Halliday, 2015, para. 9). In essence, “the more languages we have access to, the greater our capacity to intensely experience, translate experience, to know and to communicate” (Cynthia Vascak, in Haust, 1998, p. 30).

**Conclusion**

Poet Muriel Rukeyser’s observation, “*Art is not a world, but a knowing of the world. Art prepares us*” provides a meditation on the methodologies and conditions of knowing. In essence, the challenges of art offer context and preparation for working within the messiness, flux, and uncertainties of being. Blunted or honed, the edges of our fallible, human understandings are tools that cut paths through perceptions, revealing, for better or for worse, a visible world. The experimentation and speculation inherent in arts-based writing practices prepare us to approach research as a dialogue among multiple realities, materials, and diverse ways of knowing. And in emphasizing speculative methods of expression and meaning making, arts-based writing prepares us to approach the production and representation of knowledge as an ethical responsibility (Oliver, 2000) requiring sustained, creative interrogation and critical reflection throughout the research endeavor.

Creating Best Practices with Employer Partners - How to Construct Quality Off-Campus Educational Pedagogy

Cindy B. Damschroder, University of Cincinnati, United States, cindy.damschroder@uc.edu

Abstract

Starting or growing a co-op/internship program can be intimidating; for both educators and potential employer partners. In an effort to learn the pain points for both parties, opportunities to break down barriers and build bridges, and identify actionable steps to get started, faculty from the University of Cincinnati’s Division of Experience-Based Learning and Career Education conducted a two-year research project with 65 co-op and internship employers from more 15 unique industry clusters, and 50 university faculty and staff representing 24 unique institutions. This poster will graphically share the resulting findings from more than 1250 qualitative responses, and generate discussion on the educational pedagogy of creating best practices for employer partners. Find out what “the survey says”!

Keywords: Cooperative Education, Internship, Career pathway, Employer partnerships, Best practices

The University of Cincinnati is known as the institution that “invented” or began the cooperative education practice in 1906. As defined, cooperative education and internships are an immersion in the practice of workplace. At the University of Cincinnati, there are separate and distinctive definitions for the terms “cooperative education” and “internship” and it is necessary to clarify and discriminate between these in order to frame the educational pedagogy of how each is delivered by both faculty and employer partners to student participants. The definition of cooperative education (co-op) is a full-time (35+ hours per week), paid, supervised, career-relevant and work-integrated learning experience for a student. At the University of Cincinnati, co-op is most commonly delivered in alternating semester rotations with school semesters and delivered every other semester - year-round. Internships can be part or full-time, supervised career-relevant experiences for students, often completed while simultaneously enrolled in classes. These experiences are most often paid, yet can be unpaid if working for a non-profit organization.

Whether an internship or a co-op, work-integrated learning provides a student with the opportunity to learn in an off-campus setting with unique learning outcomes that differ from the traditional classroom model. This “off-campus” learning supports a student’s preparation for the world beyond the classroom and in their field of study. When students assemble experiences in the workplace, they learn to problem solve, adapt to change, develop self-confidence, and manage both time and projects in a manner that is tied to performance.

Associate Professor Cindy Damschroder and her colleague Assistant Professor Aaron Bradley in the Division of Experience-Based Learning and Career Education at the University of Cincinnati
conducted a two-year research project with 65 co-op and internship employers from more 15 unique industry clusters, and 50 university faculty and staff representing 24 unique institutions. The resulting research yielded 1250 qualitative responses and extracted key insights regarding opportunities to improve the experience for all parties engaged with educating students in the workplace - employers, faculty and staff.

**Literature Review**

Those who study learning theories generally accept that learning can happen in a variety of contexts, and therefore locations. The issue of credit or non-credit bearing experiential learning semesters notwithstanding, students look forward to applying the theories of the classroom to the “practice” of the workplace. There is a substantive body of research regarding the benefits of cooperative education from the student’s perspective yet employers who treat students as valued members of their organizations stand out to those in experiential learning and are top choices for students when applying to these positions. According to Scott Weighart,

> There are many possible motivators for employers when it comes to the rationale for hiring student employees: they are seeking cost-effective resources for getting work done; they are concerned about the high cost of benefits and like the idea of co-ops or interns as benefit-free labor; when the economy is unpredictable, co-ops or interns allow them a way to get work done without making a long-term commitment to a resource that may not be needed in the future. If the economy picks up, the employer could hire a full-time employee or additional co-op. If business gets worse, they simply can opt against hiring another co-op without having to lay-off someone and provide unemployment compensation; they have a seasonal or cyclical need or a temporary project; a co-op or internship program is a great mutual trial period to help employers and students figure out if they are a good match for each other after graduation. Given how costly it is to hire the wrong individual - as well as the fact that interviewing is not necessarily a highly scientific predictor of job success - this is an important factor in having a co-op program (7).

Nevertheless, the benefits of relationship building between the university and the employer partner go beyond this. According to NACE’s 2017 Internship & Co-op Report the average conversion rate from intern to full-time hire is 51.3% and the five-year retention rate for interns who are converted to full-time hires is 51.8% ([http://www.naceweb.org/store/2017/internship- and-co-op-report/](http://www.naceweb.org/store/2017/internship- and-co-op-report/)).

As noted in *Beyond the Skills Gap*, qualitative research with industries such as manufacturing and biotechnology in addition to interviews with community colleges and universities throughout Wisconsin resulted in a two-year study, 145 interviews representing 17 institutions and 52 companies. “What are the competencies you think are most essential for success in the workplace?... If they had to imagine a composite ‘ideal’ employee, they envisioned a hard-working individual with appropriate technical training (knowledge as well as the ability to apply technical information), solid problem-solving skills, and the abilities to communicate well, work in teams, and to continually learn new things"([http://www.naceweb.org/career-](http://www.naceweb.org/career-))
readiness/trends-and-predictions/beyond-the-skills-gap). Much of this qualitative data will be echoed when discussing the industry clusters that were interviewed during the research in Ohio.

When employers are designing a co-op program and wish to incorporate “best practices” there are scholarly sources to refer to in order to shape their program. According to Learning Outcomes and the Educational Value of Cooperative Education a program should be built around the principles for effective student learning such as: encouraging feedback; setting expectations; an expectation for student success; transfer knowledge to student and monitor progress; and design a program that has an educational focus or “purpose” (Cates & Jones, 1).

Research Methods

Professors Damschroder and Bradley held four workshops in four cities across Ohio; Cincinnati, Columbus, Cleveland and Toledo. At the onset of these workshops an initial goal was to facilitate dialogue with both existing and prospective co-op and/or internship employer partners, supplemented with training “tips” for best practices. Dialogue was facilitated with a slide deck focusing on discussion topics such as brand building on campus, interviewing techniques and onboarding methods.

The first workshop, held in Cincinnati had more than 75 attendees traversing a wide variety of industry sectors and discipline hiring needs. In addition to employer partners in attendance however, where educators from other academic institutions who were equally interested in learning about employer partner practices, needs and their perspective with on-campus engagement. A rich dialogue ensued, existing employer partners came to the workshop armed with a wide array of questions as well as concerns that ran deeper than the “surface-level” discussion of brand building, recruiting and onboarding. As the workshop evolved, it revealed an authentic desire for either “following” or “establishing” best practices and this set the stage for the subsequent three workshops.

Learning outcomes of the Columbus, Cleveland and Toledo workshops addressed “pain-points” from the perspective of both the educator and the employer and how to work beyond them; opportunities for quick wins in a program of any size; and long-term strategies for growth and program improvement. In all, 1250 qualitative responses were gathered from the 65 co-op and internship employers from more than 15 unique industry clusters and 50 university faculty and staff representing 24 unique institutions.

Discussion

The distillation of the qualitative responses led to the creation of both an educator and employer infographic as a means to convey the “best practices.” Focusing on the employer account, broad categories such as: On-Campus Engagement, On-the-Job Engagement and Future Planning are defined. On-Campus Engagement is inclusive of brand building and the ability to tell your story, envisioning your program and the “why,” crafting a job description and preparing for
interviewing and having a pre-hire engagement plan. On-the-Job Engagement consists of student onboarding, setting expectations, providing feedback in real-time, connecting co-ops/interns throughout the company and providing end of term evaluations. Future Planning should include an exit interview and an examination of how the semester “went” - what went well and what can be improved.

Conclusion

The process of building and growing a co-op or internship program is not a “cut-n-dry” static process rather it is “fluid” and ever changing as organizational needs change, students are hired for different projects and with different competencies. Educators/advisors strive to prepare students with resumes and portfolios that target appropriately the correct audience, they empower students with skills to research companies thoroughly and practice mock interviews. Furthermore, once the co-op/internship has concluded the teaching pedagogy needs to be in place for student reflection - what, so what, now what. With reflection on the part of both the employer and the student, and leveraging these “best practices” learnings - educators, advisors and employer partners can work together to make experiential learning at best a conversion to full-time hire and at the least a memorable journey!

Author Biography
Cindy Damschroder

Associate Professor and Director of the Design and Arts Initiatives, Cindy is a long-term member of the Division of Experience-Based Learning and Career Education. As an advisor who facilitates placement of the Interior Design students into their co-op jobs on alternating semester appointments, her instructional background has been focused primarily on first and second-year learning. The undergraduate environment and how successful learning objectives, modules and assessments are elements of Professor Damschroder’s research pedagogy.

Cindy is a passionate advisor and educator that places students at the center of their educational goals. She strives to create an experiential environment that engages the student, helps them to feel personally invested in their learning, and often offers advice and counseling to those students looking to define themselves within a large-scale university environment.
Understanding the [design] problem in addressing human-building interfaces

Julia Day Kansas State University, Assistant Professor, juliakday@ksu.edu
Bryan Orthel Kansas State University, Assistant Professor, bdorthel@gmail.com

Abstract

As society shifts towards an increasingly sustainable future, high-performance buildings can provide a means to meet sustainability and energy efficiency goals. Occupants in high-performance buildings are often expected to interact with building systems to maintain individual levels of comfort and productivity. However, the critical role of the human-building interface is often ignored (Day & Heschong, 2016). Too often, building controls are not intuitive and poorly understood by typical users. Conversely, some buildings rely on entirely automated building systems (e.g. lighting, shading, HVAC systems), which take control away from occupants. This approach is largely unpopular with building occupants. The literature suggests people desire and prefer control of their interior environments (e.g., Escuyer & Fontoynont, 2001). Designing a high-performance building that effectively engages users presents a more complex problem than most designers are prepared to handle.

Design teams require an ability to see the whole situation—from how the parts of the system work to how users will engage and adapt the system. This ability relies on systematic efforts to understand broad swaths of human behavior and design research, which go beyond computation or modeling (e.g., Huppatz, 2015; Rittel & Webber, 1973). In this context, design and design research supports third order (activities and processes) and fourth order (environments, organizations, and systems) design problems (Buchanan, 1999). Creating design teams, who can comprehend a whole situation, requires reframing how clients and designers understand design problems. This draft paper links theory about design problems with practical processes for using design research to improve the human-building interface.

Keywords: interior environment, human-building interface, design research, design theory

As society shifts towards an increasingly sustainable future, high-performance buildings can provide a means to meet sustainability, energy efficiency goals, and more. Many sustainable buildings exist, and may target goals such as water use reduction or energy efficiency; these goals are important. However, a high-performance building is designed to go beyond building performance metrics, and as such, it is intentionally designed to maintain sustainability goals while also enhancing occupant productivity and overall well-being. Specifically, a high-performance building “integrates and optimizes all major high-performance building attributes, including energy efficiency, durability, life-cycle performance, and occupant productivity” (EPA, 2005).
This paper presents a literature review of relevant design thinking concepts and research, which provide a theoretical framework for understanding the complexity of human-building interfaces and corresponding occupant interactions with the built environment. Key elements from the design thinking literature are explored and supported by human-building interface examples.

better understand how designers can encourage occupant interactions with the built environment while also supporting sustainability goals and occupant productivity and comfort.

Human-building interface: Context
In high-performance buildings, occupants are often expected to interact with building systems to maintain individual levels of comfort (visual and thermal) and productivity. For example, an individual in a passively ventilated office building may be expected to add or remove layers of clothing, close or open windows or window blinds, or interface with HVAC building controls to maintain thermal comfort. However, in some buildings, the critical role of the human-building interface is often ignored and these actions may not be possible (Day & Heschong, 2016); these types of adaptive actions may be poorly understood or the human-building interface may not be intuitive for the majority of users. In other buildings, controls for adaptive comfort opportunities may be completely removed and may rely entirely on automated building systems (e.g. lighting, shading, HVAC systems), which take control away from occupants. This approach is largely unpopular with building occupants. In some cases, occupants may unsuccessfully attempt to override a human-building interface, leading to discomfort, frustration, and/or misuse of systems (Day & Heschong, 2016).

The literature suggests people desire and prefer control of their interior environments (e.g., Escuyer & Fontoynont, 2001). Research has shown that occupants may even accept a wider range of temperatures as comfortable if provided with local control of their environment, which may support energy use goals. On the other hand, if controls are not used properly or misunderstood, the use of windows, window treatments, lighting, and other building systems may impede energy goals. It is important that occupants understand their environment and how to control it effectively (Day & Gunderson, 2015; Janda, 2011). Designing a sustainable building that provides comfort and maximizes productivity for occupants can become a difficult task quickly. The challenge is not just about energy, building form, or technical systems; the challenge engages how people understand and will regularly use the spaces and systems. Teams of designers--including engineers, architects, interior designers, and other experts--work together to solve these problems, but still fail to develop solutions that operate and meet user experience expectations. Designing a high-performance building that effectively engages users presents a more complex problem than most designers are prepared to handle.

Literature Review
Design teams require an ability to see the whole situation—from how the parts of the system work to how users will engage and adapt the system. This ability relies on systematic efforts to understand broad swaths of human behavior and design research, which go beyond
computation or modeling (e.g., Huppatz, 2015; Kimbell, 2011; Rittel & Webber, 1973). Design teams also require a clear understanding about the implications of their work. While some design problems will be addressed by physical solutions, design is now communication more than product (Buchanan, 1985). In this context, design research supports third order (activities and processes) and fourth order (environments, organizations, and systems) design problems (Buchanan, 1999). The third and fourth orders of design can be leveraged to understand interactions with the environment and how to design for those interactions.

Design problems
The framework for this argument rests on Rittel and Webber’s definition of the wicked problem (1973), as extended by Coyne (2005). Rittel and Webber’s explanation presents certain problems as indeterminate and impossible to frame and safely solve without unknowable consequences. Specifically, wicked problems (1) have no set definition, (2) have no identifiable stopping point, (3) only offer variably good-to-bad solutions, (4) have untestable solutions, (5) cannot be solved by trial and error, (6) are not bound by a “set of permissible operations,” (7) are unique, (8), are linked to other wicked problems, (9) offer multiple explanations of conditions, and (10) do not permit the solver to be wrong. Most wicked problems have social components. The wicked problem defies singular human recognition.

Rittel and Webber were reacting to earlier framing of complex problems through systems theory. Systems theory presented the possibility for a scientific truth, which could be determined through coming to know the interrelated character of related parts. The wicked problem approach denied that such a truth could exist. Coyne (2005) noted that both assumptions were outdated in a postmodern world that struggled with questions about who over what. Today, the question of who has been replaced with the multitudinous acceptance of unquestioned, asserted whys. Assertions of ethical value now trump identity.

Knowing how or what to do is insufficient when the questions become about why, values, and goals (e.g., Meadows, 1999). Goal-finding still turns out “to be an extraordinarily obstinate task” (Rittel and Webber, 1973, p. 157). Our perception of acceptable and desirable outcomes has shifted from assertions of efficiency and economics, to questions of moral and ethical choices. For the professional tasked with addressing a problem in the twenty-first century, passive or dispassionate resolution is inadequate. Designed solutions have social, cultural, and intellectual purpose far beyond their tangible manifestations. Design must communicate to convince others to act.

Design as action
Design is now an action. As such, design is framed as “integrative thinking” (Buchanan, 1992, 6). Design should now be considered two types of actions: thinking and communicating. Buchanan (1992, 1999) emphasizes design as a way of thinking by modeling four orders of design: symbolic and visual communication, material things (or processes for making), activities and organized services, and complex systems for living. The orders can be simplified as signs, things, actions, and thoughts. He explains that these orders, “properly
understood and used, ...are also places of intervention shared by all designers, places where one discovers the dimensions of design thinking by a reconsideration of problems and solutions” (Buchanan, 1992, 10). This framework provides the basis for innovation in considering wicked problems by drawing together professionals who “share a mutual interest in...the conception and planning of [what Herbert Simon calls] the artificial” (Buchanan, 1992, 14).

At the same time, design outcomes are communications. The design of signs, things, actions, and thoughts is only partially about manipulating material, space, or tangible characteristics. Instead, the designer’s goal is to communicate an argument that will shape others’ thoughts and actions. Buchanan (1985, 2017) presents this as design rhetoric focused on **logos** (or a technical structure) for thinking about an issue), **pathos** (or emotion and appropriateness to a given situation and user), and **ethos** (or character and identity). A design (communication) based only on one or two of these characteristics is incomplete. The most convincing design will embrace all three; the designer (or design team) cannot hope to resolve a wicked problem without convincing others that a solution is best or most. The ways they do so will demonstrate technical resolutions, the inherent nature of the problem, and the humanity for solving the challenge.

Considering our premise requires one further step. The separation of words and things “has proven nearly disastrous...for [designers’] ability to understand, let alone discuss or shape, new technologies...that support practical life” (Buchanan, 2001, 186). If designers have exclusionary and narrow foci, they miss too much. Designers must create “whole products” that include not only the expression of ideas in language or visual media, but also integrate recognition that the design is situated in the converging paradigms of designer, individual user, and humanistic society (Buchanan, 2001). The multiple people on a design team, who are thinking about a problem from different directions, become crucial to integrating interdisciplinary knowledge, the shifting paradigms, and recognizing novel, effective, and powerful solutions.

**Design thinking**

A core premise of design thinking upends the linear notion of problem definition preceding problem solutions. Instead, design thinking’s integrative approach relies on the co-evolution of understanding--of both problem and solution--through the process of developing both (Dorst & Cross, 2001; Michlewski, 2008). Cross (2010) stated it as the designer’s ability to resolve “ill-defined problems by adopting a solution-focused cognitive strategy and productive or appositional styles of thinking...[using] sketching, drawing and modelling” (19). When designers address indeterminate problems, they cannot know the topical areas to be considered, the range of possible solutions, or the scope of a project because the problem is inherently outside those boundaries. As a result, design is a way of thinking and acting separate from pre-set boundaries. “Design has no special subject matter of its own apart from what a designer conceives it to be” (Buchanan, 1992, 16). It is the designer’s role to focus and make tangible the characteristics of the problem being faced. This does not change the problem’s determinacy, but provide ways into explore and respond.
Design is socially oriented. Design addresses wicked problems, which are inherently social, by proposing human-based solutions. These solutions are social because they are about ethics, values, and communication rather than material, location, or technical processes. The only way designers can explore solutions is by considering how humans interact and act in context. An understanding of both human behaviors and social context becomes critical.

Design is socially oriented in a second aspect. Recent literature has highlighted ways that team-based design is crucial to successful problem solving (Eris, Martelaro, & Badke-Schaub, 2014; Roise et al., 2014; Ingebrethsen, 2013; Jonson, 2005, Oxman 1997). The communication between design teams is critical to how the team members understand and address a problem (Purcell & Gero, 1998). Just as sketching is important to all individual designers to “handle different levels of abstraction simultaneously” (Cross, 1999, p.35), communication between team members using graphics and oral exchanges is essential to the team shaping understanding of ideas (Orthel & Day, 2016). How teams communicate and think is fundamental to their potential success in addressing any wicked problem, like human-building interfaces.

Because these problems are so complex, and inherently “wicked,” it is important that they are approached from an interdisciplinary team-based design perspective. “When designers do not have mastery of a subject, they have become adept in collaboration with engineers, computer scientists, or content experts” (Buchanan, 2011, 195). To solve the problem of human-building interface interactions, designers cannot rely on their own understanding in isolation from engagement with other experts and real users. The team becomes more than a group of like designers. This approach to design teams must be interdisciplinary. Creating design teams, who can comprehend a whole situation and understand the scope of design’s problems, requires reframing how clients and designers understand design problems.

**Encouraging interactions through design**

Design teams must bridge the technical and the human. These characteristics are not oppositional. But it is too easy (and too frequently a problem) that designers only consider one or the other. A design solution’s technical wizardry rapidly and effectively acts, but too few people understand how to use the design. Or, a design is aesthetically desirable, but ineffective in solving a problem. Neither proposed solution can be considered a successful design. We see this challenge emerge specifically in the realm of building energysystems.

According to Buchanan (1985, 2017), every successful design embodies: **ethos, logos,** and **pathos**.

- **logos** – reason – is there a technological reason for the product’s existence?
- **pathos** – affordances and accessibility – is the product usable?
- **ethos** – character or voice – is the product desirable?

A strong design is a balance of all three elements. Oftentimes designers are able to achieve logos and the pathos, but fail to integrate ethos. So many interesting technological ideas may fail because they do not have usefulness or desirability (Buchanan, 2017). Each of the three characteristics–logos, pathos and ethos–are important, but in the context of human-building interfaces, an additional factor may be important to consider.
We propose a fourth dimension: *kairos*. A design must have a reason, usability, and desirability, but in an environment designed for interaction, a design or building interface will only be successful if the occupant or the *actor in the environment* understands how to use or operate the building interface. The Greek word *kairos* is defined as a *propitious moment for decision or action*, or an opportune moment. In an interior environment, one that depends upon human-building interfaces, the success of the design may rely upon signaling or identifying opportune moments for the occupant to act or interact within the interior environment. The solution must communicate with and educate a user about how to act. The solution is only successful when it is put into the action of time and use. Just as time offers a fourth dimension in relation to geometric position, *kairos* activates a design through use. More, the designer cannot leave *kairos* to fate. The design must be considered for how it will communicate with users in an ongoing and productive way. In a human-building interface, this success requires that the design do more than save energy, mechanically work, or be aesthetically appealing. The design solution must extend itself forward.

**Human-building interface: an applied example**

For example, in a naturally ventilated space, where occupants are encouraged to open and close windows for ventilation and thermal comfort, a successful design might include a natural ventilation system that signals opportune moments or actions to occupants. In this simple example, the logos, or rationale for the system is the potential for fresh air, comfort, and energy savings. The pathos may be the accessibility of the window (e.g., can occupants reach the window and open or close it?). Ethos may be more difficult to illustrate, but desirability of the product would certainly relate to the desire for thermal comfort. The *kairos* could be embodied by a red/green light system that indicates favorable outdoor conditions. When it is too humid, too hot, or air quality is poor, the light near the window is red (signaling to occupants: “do not open”); and when outdoor conditions are conducive to occupant health and building efficiency, the light turns green (signaling to occupants, that they may interact with the building interface if desired). This example is oversimplified; opening and closing a window should not be difficult and certainly seems less-than “wicked.” However, in a high-performance building, shared by many users, occupants can quickly undermine design intent and function (e.g. energy efficiency). Clearly communicating these intentions and beneficial behaviors is part of the design’s (and designer’s) responsibility. Additionally, the *kairos*, as discussed in the above example, will fail if the goals and objectives of the system are unclear, or if the interface is designed in a way that it not intuitive or easily understood by the occupant.

**Discussion**

In the case of human-building interfaces, designing to encourage occupant interactions with building systems for energy efficiency and comfort can become exponentially more complex when occupants are in a shared environment (e.g. an open office or public space). Occupants may also be influenced by others’ actions, perceived norms, cultural expectations, or social cues (Jain et al., 2013). In these cases, the design should support social interactions and encourage desired actions, through both careful interface design and behavior change.
strategies (Day & Gunderson, 2015). In fact, many behavior-based energy efficiency utility programs encourage behavioral energy savings to mitigate some of these social factors through direct and indirect feedback, motivations, prizes, competition, etc. “However, such social interventions will only work to the extent that the building interface allows occupants to take an action” (Day & Heschong, 2016, p. 8-1). These behavior-changing strategies are likely to fail if occupants are unable to interact, or do not understand how to act.

Therefore, a successful design certainly requires the balance between logos, pathos, and ethos, as defined by Buchanan. But to truly thrive in an interactive environment, where occupants are expected to engage with building interfaces, people must be armed with the knowledge for how and why to take action, such as education or outreach (Janda, 2011; Day & Gunderson, 2015).

Kairos, a design characteristic that brings the design solution forward into users’ understanding and everyday consciousness, become essential parts of the design’s success. Whether through the design of the actual interface, or through other means, kairos activates the design into a self-fulfilling and perpetual solution to a problem. Designers must match design solutions with the user(s), which requires understanding humans in their social context. In addition, the designer must effectively present the design in a way that brings the user into the opportune moment to understand, use, and implement the design into regular practice. Designers recognize the importance of thoughtful solutions that seek a balance between building efficiency and healthy, functional and productive environments for occupants. How to meet this goal is often less clear. Interdisciplinary design teams committed to dynamic intra-team communication and integrative consideration of broad issues provide one step forward. Success also requires reconsidering the design problem to recognize design as action and communication. The desired solution will engage technical and physical expressions, but must also act across time to match kairos with logos, ethos, and pathos. The complexities of human-building interfaces are just one example of the wicked problems design teams will face. Design, used in this way, can be applied to even more complex, consequential problems currently facing our society. As such, designers are uniquely suited to further address wicked problems in ways that bridge the gap between the human and the environment.

Biometrics For Babies- Human Centered Technology Design to support infant immunization and healthcare delivery in resource limited settings.

Carl Demolder Research Assistant, UC San Diego cdemolder@ucsd.edu
Deborah Forster Eliah Aronoff-Spencer

Abstract

Identifying Infants can be harder than it seems. Particularly in remote and limited resources settings, rapid and accurate identification of infants presents an unsolved complex sociotechnical problem. Imagine a long line of caregivers, each carrying several children, waiting outside in heat and humidity for required vaccinations. Caregivers may only know the infant's given names: how can the they be identified for record keeping? Vaccination cards are notoriously unreliably and easily lost, mistakes abound. Recent technology-centered attempts that used adult solutions to identify children have failed.

In order to develop a new, infant-centered solution from the ground up, we assembled a diverse team of engineers, clinicians, ethnographers and designers and followed a Human Centered Design (HCD) approach of ethnography, rapid prototyping and testing. We examined all common modalities used in adult biometrics-- ear, iris, retina, face, foot, palm and finger recognition and compared technical feasibility, usability and acceptability for the infant use case. We prototyped many infant-centric devices and arrived at lead candidates using modified contact vs non-contact palm and finger scanning. Frequent design-test cycles were critical as the complexity and changing nature of infant physiology, behavior and caregiver dynamics could not be predicted, only tested with subjects. This was compounded by moving targets of evolving infant-centric software, hardware and device design.

In summary, we report here an HCD based approach to infant biometrics. We developed and tested robust, socially acceptable technologies that adapt to the tiny, sensitive yet changing fingers of very young infants.

Keywords: infant biometrics, fingerprinting, vaccinations, human-centered design, prototyping, image analytics

Infant are not little adults. They cannot tell you their name and despite significant effort they are misidentified at an alarming rate during critical interventions such as immunizations and healthcare delivery. While each year 85% of children around the globe receive vaccines, saving many millions of lives, lack of methods to tackle the identity problem continues to jeopardize the health of millions more children. This
problem is compounded in poor or remote settings that often have the greatest needs yet the least resources.

Adult biometrics technologies such as modern fingerprint scanners have been proposed as potential solutions. To date these approaches have met with limited success. Infant hands are not just smaller versions of an adult—or even a toddler-hand. Proportions, subcutaneous fat distribution, feature flattening and developmentally-dependent reflexes make children significantly different from adults. Capture methods in infancy present interaction challenges. Neonates wiggle a lot. They do not understand language. Caretakers are not always comfortable with medical personnel and technology. Techniques that work in the laboratory often will not work in the field.

Kalisky (2017), following Jain et al. (2004) and others, summarized research efforts on various biometric traits that were tried or at least considered as appropriate for infants (Table 1). Traits that may be very successful in identifying individuals across their lifespan (e.g., iris) are difficult to obtain in field clinic settings where cooperation of infant and acceptance of caregivers are critical. After extensive review of previous work by others in addition to our own exploration, including an international online survey of vaccination clinics, we took a fingerprints-first approach, while developing palm printing.
methods in parallel and capturing ear and facial data to be examined as needed.

**Design Approach**

The project was based on two premises. The first was the necessity to interact with infants and caregivers at every stage of the ideation and prototype development. The second was the realization that the success or failure of this system would be determined by the efficient coupling of design and development with trackable, quantitative data. Evidence-based design required measurables, yet these were interconnected and evolving, in part dependent on cumulative data collection and analysis, in part dependent on the quality of the given prototype, in part dependent on the quality of the matching software, in part dependent on the infants actually being tested at that time. A wicked problem. The design of the device, of the data analytics, and of the interaction with infants and caregivers had to develop together (Figure 1).

![Figure 1: Overall design approach](image)

**Design Research Activities**

The continuous cycle of test and refine can also be seen as a braiding of three distinct yet utterly co-dependent threads of expertise: (1) interaction design during the fingerprint capture sessions, (2) hardware prototype development, and (3) the software pipeline.

(1) **Interaction Design**

*Palm / Fingerprint Capture Session – Minimum Viable Socio-Technical Complex Setting.*

The fingerprint capture sessions during the pre-pilot phase took place in an office-like environment that maintained the lab-infrastructure required to monitor, record and troubleshoot. We required from the outset that recruited caregivers return with their infants to multiple sessions – both in order to mimic the potential return for vaccinations in the target setting, to study the changes in age, and to receive input on the interaction design process from experienced users.
The print capture setting during the research and development phase in the lab-office differs from the clinical settings in the local hospitals and will differ from field pilots. To begin with these capture sessions were crowded with other team members and expert observers from various domains (neonatal doctors, optics specialists, mechanical engineering, external design consultants). Figure 2 represents the current setting in the lab-office. The final field deployable system will be managed by a single, locally trained nurse / health practitioner.

Ethnography for design At the outset of the project, prior to Institutional Review Board approval to work with infants, the greatest challenge for the team was to understand the interactions of the infant hand with a device, in the absence of infant hands. We used anatomically realistic neonate dolls of various races, we 3D printed and cast phantoms to simulate real children. We studied the kinds of interactions possible between a person and the infant (doll) and produced hand drawn renderings (Figure 3). These were displayed in the design studio as a constant reminder of the challenges being faced, and ultimately of the realization that frequent and constant testing with representative samples of real infants was the only viable solution.
The interaction arc. Once work with infants began it became clear that it was not enough to consider the position of the infant before contact with the capturing device. The infant’s response was more critical. Limp fingers reacted by curling, flattened hands recoiled. When the tips of finger pressed against the flat surfaces of our devices, they bunched up. Each of these represented a potential failure mode.

Not only did the ethnographer observe and record each session, other team members recorded close-ups and video clips of these dance like sequences of big hands and small hands, surfaces and body parts. The practitioners – the persons managing the device to capture the fingerprint – were often not aware of their own micro-dynamics, yet gradually developed sensibilities they could articulate. We began to understand the nuances of pressure and movement and maneuvering that were critical to prototype development. The ethnographers created collages of closeups taken during the capture session to display on large vertical boards – annotated with emerging insights re patterns of holding and infant / caregiver reactions. These displays, and a large screen on which video clips and images of the print captures were routinely examined offered a shared space that spanned the expertise represented in the group.

(2) Hardware - Early Prototype Development
A major hurdle to obtaining good fingerprints is that the skin of the infants deforms when in contact with a rigid surface, e.g. the glass “platen” of a traditional fingerprinting device. As a result of these observations, we developed and tested imaging methods that did not require physical contact. The evolution of contact vs non-contact prototypes is shown in Figure 4.
(3) Software Pipeline – Rate, Process, Enroll & Match

As the success of the system depends on the image quality and its acceptance in both enroll and match phases, what transpires in any given print capture session has to be evaluated against a complex processing and analytic pipeline. We devoted significant and early effort to develop a software processing and matching pipeline to supply ground truth of progress towards accurate print capture and matching (Figure 5a-b).

Figure 4: Design Evolution Approach Taxonomy, illustrating, to the right, contact method approaches, and, to the left, non-contact approaches (adapted from Kalisky, unpublished)

Figure 5a: Processing pipeline – image analysis: an example of an early version of a processing pipeline for a single image
Design Research Activities - Summary
The shared understanding necessary to carry through the complex design cycle required multiple (and often disparate) specializations to work together. Despite obvious grouping during work—such as engineers and interaction experts working together in different settings, every expert had to be willing to be aware of and sometimes contributing to other facets of the project. This required more frequent communication and task switching than might be promoted by traditional teamwork models. Tools such as Slack promoted shared workflow awareness, yet breakthroughs began only as engineers handled the infants and interaction designers were forced to use software while actually testing children.

Design Research Insights
The interdependent work ethic that developed in the team challenges the distinctions between expert threads of (1) interaction design, (2) hardware and (3) software development, yet it is important to consider each thread in turn as its own entry point into the complex socio-technical system.

(1) Interaction Design Insights – Understanding Failure Modes
Detailed observations and documentation of each print capture session could not on their own suffice to predict the outcome measures that counted as evidence—image quality measures such as contrast, coherence etc. Thus understanding failure modes took us beyond what any sub-group would have to contend with in isolation. A basic failure analysis is shown in (Figure 6). It establishes the interdependency of factors that must be co-managed for successful capture of prints.
(2) Hardware Insights – Device Modularity

Over time we learned to distinguish optics and illumination issues and image processing from interaction design challenges which allowed for parallel prototype production (Figure 7.) Our development trajectory evolved toward a modular technology stack on which a variety of caps could fit interchangeably to test contact and non-contact approaches and make affordances for the changing physiology, shape and behavior of the infant hand.
A. Early prototype – contact and non-contact caps. The device includes fiber optics designed to be closer to the camera – and to absorb stray light – by providing angled illumination, and adding a diffuser.

B. Design for non-contact capture of an infant’s palm – includes large field of view but low resolution and direct lighting.

C. Razor handle, shaped for both contact and noncontact capture. The device form intended for better ergonomics for the practitioner. It includes a polarizer / analyzer – the use of a variable lens made it possible to do both contact and noncontact with the same device. It featured angled light illumination (like in A.)

D. Noncontact only with direct light – larger field of view with high resolution – fixed focal length – not a lot of flexibility but effective in noncontact capture

Tops – include rollers, spring mechanism to accommodate for varying sizes.

(3) Software Insights - Extending and Integrating Pipeline

After the arduous development of a software processing and analytics pipeline – the software experts focused on integrating the print capture, processing and data management directly into the capture process by developing a unified Graphical User Interface (GUI) (Figure 8) that simplified data capture and gave real time feedback on print quality and matching.
Design Insights - Summary
Our work required a multidisciplinary team with an organizational structure that allowed for both individual contributions and shared collaboration. This itself required significant consideration and iterations and might be considered its own form of complex sociotechnical problem. This presented the realization that teams assembled to solve “wicked” problems—may themselves be “wicked” problems. We found that common version control and sharing tools such as GitHub, Slack and Google Drive greatly improved efficiency. Additionally, traditional failure mode analysis and visualization served to align mental models amongst the team and assure directed progress. In the end, frequent testing and iteration by a cohesive team was the only viable course.

Conclusion
This paper describes the complex design challenge of developing biometrics for infants. Unlike prior work that attempted to adapt adult-centric technology, we started before the assumed solution and focused upon a clear goal; identifying very young infants (neonates) in extreme environmental conditions. From the beginning, we sought to build the necessary technology in concert with infant and caregiver preference and interaction and used HCD methods to guide this process. Based on requirements uncovered during field study we targeted development of a robust device that could be used by a community health worker with no specialized training, in any setting and without support. Moreover, the procedures and interactions with children would have to be acceptable to caregivers and reliably capture high quality prints needed for the functioning and trust of the overall systems. Overall the early acknowledgement of the complexity of the problem, the use of Human Centered Design Thinking and a efforts to assure a collaborative, diverse and intentional team led to the
project’s success. We propose this merging of design thinking, team science and technology design may be applied to similar, complex sociotechnical problems in the future.

Key Author Contributions

**Carl Demolder:** Research Technician in the Prototyping Facility of QI-UCSD. An undergraduate in Mechanical and Aerospace Engineering. Contributed mechanical design and prototyping, electrical engineering and software design and helped with experimental design. Initiated and contributed figures and text to this manuscript.

**Tom Kalisky:** Masters in Mechanical and Aerospace Engineering. Co-lead mechanical design and prototyping, helped with experimental design and contributed figures and text to this manuscript.

**Yunting Zao:** Masters in Electrical and Computer Engineering. Co-lead mechanical design and prototyping, helped with experimental design and contributed figures and text to this manuscript.

**Daniel Johnson:** Masters in Mechanical and Aerospace Engineering. Co-lead mechanical design and prototyping, helped with experimental design and contributed figures and text to this manuscript.

**Courtney Avery:** Research assistant. Responsible for infant testing, contributed insights and aided with figure design of the manuscripts.

**Deborah Forster:** Cognitive Scientist and design-context researcher. Led interaction and human centered design and contributed significant text and content to the manuscript.

**Eliah Aronoff-Spencer:** ID Physician and Health Technology Designer. PI of the study, contributed text and edited the manuscript.
Setting the Course: Instilling, Comprehension, Curation, and Implementation of Research in Four-year, College Graphic Design Programs

Madonna G. Dersch SCAD Graphic Design and Visual Experience Program Petersburg, VA, USA, research.dersch@gmail.com

Abstract

Graphic design students require a foundation in understanding, utilizing and conducting research. The discipline would benefit from standards for quantitative, qualitative, mixed-methods and practical approaches to graphic design-specific research. This paper examines the role of graphic design research in college-level graphic design pedagogy.

This study is motivated by two research questions: [1] what theoretical analysis and practical approaches to graphic design research are graphic design educators currently implementing? [2] How can college-level graphic design educators build a culture of research literacy in graphic design baccalaureate programs?

Literature describing the theoretical and practical instruction of graphic design research in college-level graphic design education is limited. The intention of this study is to advance the understanding of how graphic design educators define and implement graphic design research, first through qualitative analysis of a survey of four-year, graphic design degree program professors across the U.S. followed by in-depth interviews with published educators practicing research.

The study’s interviews elaborate on the specifics of graphic design research through the lenses of professors developing and implementing graphic design research in four-year undergraduate programs, in their own practices, and in the discipline-wide conversation and study of graphic design research itself. In the study’s conclusion, potential future research is discussed.

Keywords: Design education, design research, design science, graphic design, graphic design research, interdisciplinary design

The theoretical and practical instruction of the discipline of graphic design, the manner in which it is defined and taught in its educational programs, and the determination of the need for disciplined inquiry in these programs and the profession, indicate the evolution of the profession and provide insight into trends developing in the practice. The intent of this paper is to create a framework for the discussion about disciplined inquiry within the education and practice of graphic design.

Literature Review

Central issues in the field of graphic design research range from the definition of graphic design itself to the definition and nature of graphic design research. A lack of consensus is
compounded by nomenclature frequently being used interchangeably or differently. Discussions revolve around the questions of how graphic design research is conducted, reported, applied, and taught. Therefore standardization in both methodology and nomenclature will help to clearly define and communicate concepts.

Defining graphic design research is complex, as it takes many forms. Roth (1999) has noted the difference between design research and design studies, explaining that design research is methodological and project-oriented while design studies is an approach-based, scholarly process of systems and solutions. Poggenpohl (2009) states that research “…Gives rhetorical strength to interdisciplinary arguments and decisions,” (p. 13), while Krippendorff (2007) argues that the use of the term “design research” borrows a word associated with science and therefore has adopted science’s reputation without adopting science’s methodology (p. 67).

After compiling a litany of contradictions of which designers are culpable when reviewed against scientists, Krippendorff concludes with a rejection of the term “design research” because the terms reflecting the two disciplines are contradictory. He explains that research investigates the past (that which already exists), but design creates for the future (innovation that does not yet exist) (p. 79). Krippendorff argues that research is counter-intuitive to what design and innovation should be and therefore is not the appropriate nomenclature for this practice (p. 79).

Background on Graphic Design Research
While the focus of this paper is on graphic design research, much of the available literature is on design research in general, particularly in architecture and engineering, through which graphic design research has evolved. In order to give a foundation to a contemporary perspective, it is necessary to briefly review the study of the topic up to this point. Bayazit (2004) has reviewed design methodologies and design science perspectives that have evolved since the 1920s: it was during that period that the scientization of design may be noted in the De Stijl and then Bauhaus movements (p. 16). Building and engineering disciplines pioneered design research studies because of requirements developed in those disciplines in the period of rebuilding after World War II (p. 28). These developments were supported by the technological developments made during the second World War that were applied during the period after the war when design flourished as a “problem-solving and decision-making activity,” (p. 22). Bayazit notes that future exploration in specific design disciplines may build from the progress made in the design-research establishing disciplines (p. 28).

The construction of Bayazit’s essay provides an overview of the topic before exploring the role of design methods in design research, after which she isolates the first and second generations of design methods, giving a timeline of the key points of reference and key players in this history (pp. 17–22). It then covers the topic of scientific research in design. The essay concludes that the topic is vast and comprehensive and needs further research (p. 28).
Design Research as a Science

The scientization of design has been a trend since the 1920s, specifically in the De Stijl movement, and then later in the Bauhaus movement (Bayazit, 2004, pp. 16–7). This discussion was notably built upon in 1981 by Cross, Naughton, and Walker who stressed the difference between the scientific and design methods, particularly because the two disciplines have such different needs and goals (1981, p. 195). They conclude that design requires tacit knowledge that is purveyed through practice and inherent in craft (p. 200)—what Cross (2006) would later come to refer to as design epistemology (p. 125).

Cross supports intellectual awareness for the design discipline through the analysis and understanding of the approaches of the likes of design innovator Kees Dorst, who compared the paradigms of cross-discipline researcher and Nobel Laureate Herbert Simon with that of philosopher and urban planner Donald Schön in order to build a unique paradigm for design research (p. 127).

Similarly, Downton (2003) describes the Dorst and Dijkhuis comparison of the paradigms of Simon and Schön (pp. 38–9). Downton imparts the need for a different understanding of the prevalent paradigm of research. He notes that a scientific worldview holds that scientific inquiry results in knowledge while other types of activities that produce findings are merely beliefs or skills (p. 56). Downton asserts that the science-dominated paradigm does not result in a complete portrayal of design and that design is not represented by science (p. 56). Design, he opines, requires additional input from non-scientific fields and from the practice of design itself (p. 56). Downton goes as far as dissecting the word “knowledge” as it applies to research, stating that research tests existing knowledge, while design produces new knowledge (p. 57).

Friedman (2008) argues that there is a misconception and misapplication of the term “tacit.” He explains that there is general confusion of categories and understanding of terminology that has been published and continually re-asserted (p. 154). Friedman observes that the term “tacit knowledge,” for example, which was defined by Polanyi in 1966, has been misused in the description of design research (p. 154). Friedman opines that tacit knowledge is used synonymously with design knowledge, and both are incorrectly considered a source of theory development (p. 154). He explains that this concept is a commonly held misconception based on the assumption that practice is a research method. He concludes that this misunderstanding is based on unverified references to the works of Polanyi and Schön (p. 154).

The 1960s was an era focused on “design science.” Cross (2001) notes that the 1960s initiated the “design methods movement.” He recalls that in an attempt to hasten solutions to global issues, Buckminster Fuller demanded a ‘design science revolution’ during the 1960s, which Fuller coined the ‘design science decade’ (p. 49). Cross relays the fluctuation of the popularity of design science over the subsequent decades and the continued link between design and science (49). Cross, Naughton, and Walker (1981) note that terms such as 'paradigm' and 'scientific revolution' are used with entirely new meanings by many disciplines (p. 197).
The sciences have different requirements and processes than design, as noted by Bonsiepe (2007) who suggests that as college-level design programs assimilated into the liberal arts and sciences programs, they were required to adapt to their models, which advanced the design research agenda (p. 27). Bonsiepe suggests that research—he notes that he is referring to design and not market research—is a requisite of complex design solutions (p. 27). He poses teaching research in a manner that is more applicable to design than science, using the terms endogenous and exogenous design research to describe these forms (p. 32). He describes endogenous design research as that which emerges from and is integrated into the design process, an inquiry in which Bonsiepe believes designers should be involved because they are informing their own practices (p. 32). Bonsiepe describes exogenous design research as an external process that observes the process of design as an object, which Bonsiepe cautions designers in pursuing (p. 32). He opines that external review of the design process by evaluators who are not designers, and who apply scientific evaluation to the design process, restrict the creativity and potential outcome of the design process (p. 32).

Some of the key themes in the conversation surrounding graphic design research include the categorization of design research, as described by Frayling (1993), Davis, and Cross; the scientization of design, which is rejected by Friedman and Krippendorff; and the categorization of design as research, which was initially introduced by Frayling and soundly rejected by Friedman. Authors Poggenpohl and Friedman have opined on tacit and explicit knowledge and how it applies to design research. Poggenpohl and Davis have explored interdisciplinary collaboration at length, an idea that is more prevalent as visual communication evolves and includes multimedia outside the traditional discipline of graphic design.

The most common theme throughout the literature is the need for further exploration and consensus on the purpose, nomenclature, and application of design research. This conversation appears to be evolving parallel to the conversation on the requisite developments in graphic design education.

Research Methods

This study focused on the implementation of graphic design research in four-year college programs. The intent of this inquiry was to get a consensus of the practical implementation of research in undergraduate graphic design curricula, how the topic was interpreted, and the perceived value by those who teach it.

The study was conducted in two parts. The first portion of the study was an online survey that was conducted over a period of two weeks at the beginning of May 2016. The second part of the study was a series of in-depth interviews with six key participants who are published researchers who focus on graphic design research and teach in four-year undergraduate graphic design programs. This portion was conducted over a period of two months from May to July 2016.

The study was guided by two research questions, “What theoretical analysis and practical approaches to graphic design research are graphic design educators currently
implementing?” and “How can college-level graphic design educators build a culture of robust research methodology for graphic design education?” The purpose of the survey was to get an overview of the current culture of graphic design research within the community of the profession’s educators, while the interviews delved into the topic with published, practicing graphic design educators conducting their own research and teaching research methods to their undergraduate students.

Survey
The instrument used for the first part of the case study was a survey of thirty-eight questions, two sample verification questions, and eleven demographic questions. Of the instrument’s thirty-eight questions, five questions were inquiry into the respondents’ interpretation of graphic design research. One question inquired into the respondents’ professional, practical use of graphic design research. Fourteen questions evaluated the types of research utilized by the respondents for their professional, practical use, which could then be compared to the responses already given on the interpretation of graphic design research. Four questions inquired into the respondents’ implementation of graphic design research in their undergraduate graphic design instruction. Finally, fourteen questions, which mirrored the questions that evaluated the types of research utilized personally by the respondents, inquired into the types of graphic design research that the respondents found important to their undergraduate graphic design instruction. The instrument was tested in a pilot before being disseminated to a focused group of graphic designer-educators.

The participants for the study were located and selected through online data accumulation that was identified through two professional design organizations, the website for AIGA, the professional association for design and the website for National Association of Schools of Art and Design (NASAD).

The primary approach taken to the survey data was inductive analysis, with codes created to analyze the data and begin to categorize and find commonalities between the responses. The analysis continued with descriptive and exploratory analyses to make connections between the established codes, which were created and applied in MAXQDA 12.

The survey data was coded, and the metadata was then compared between individual participants to compare answers between types of institutions, geographical location, age of participants, levels of education, and other factors, which can be used to measure variables and test hypotheses developed during the study’s literature review.

Survey Findings
Themes that emerged during analysis of the survey data supported the themes found in the discussion in the study’s literature review, particularly that of Davis’s (2015) three approaches to design research, which are [1] as an act of discovery of knowledge that the discipline then develops into principles and theories, [2] as knowledge developed through practice, and [3] as context-specific knowledge (pp. 132–3). As expected, there was a breadth of interpretations of graphic design research. Over fifty percent of respondents
believe that graphic design research should be developed as its own practice. The next largest percentage for this question is twenty-nine percent of respondents who believe that graphic design research should be developed from other design disciplines. This shows an inclination of the respondents to create the discipline’s own methodology, rather than take methodologies from social sciences.

Seventy-six percent of respondents said they used interdisciplinary collaboration in their own practice, with seventy-four percent saying that they teach the technique to their students, and forty-eight percent of respondents saying that they require interdisciplinary collaboration of their students.

Eighty-six percent of respondents say that they currently teach research as preparatory work assigned for design projects. Likewise, responses to the question “How do you think that graphic design research ideally should be taught to undergraduate graphic design students?” were largely in favor of integrating research into curricula.

One-on-one Interviews

Interviews used a Semistructured Interviewing format based on the study’s research question (Figure 1). The sample for the interviews was a purposive sampling of a target population who were chosen because they are teaching, practicing graphic designers who conduct research and author articles, books, and presentations on graphic design. The participants Audrey Bennett, Juliette Cezzar, Behnoush McKay, Kelly Murdoch-Kitt, Paul Nini, and Mike Zender were interviewed by phone or skype and recorded on two devices with written observational notes. The interviews were transcribed and then coded using the following code system:

1) Definition of research
2) Implementing student research
3) Interdisciplinary
4) Personal, professional research
   i) Implementation
5) Qualitative
6) Quantitative
7) Social responsibility
8) Teaching research
   i) Applied research learning
   ii) How research is taught
   iii) Ideal teaching of research
   iv) Research courses
9) Validating work/tenure

Once coded using these key concepts, the interviews’ themes were accumulated and compared to elucidate relevant findings.
Discussion

The study suggests that the challenges that currently affect graphic design research include a consensus in nomenclature, standards for graphic design, an unclear understanding of the role of graphic designers, the changing role of graphic designers, changing media, and the development of terminology and methodology from other disciplines. However, the evidence suggests that the discipline has numerous areas of strength that are already being applied. Collaboration, both with other graphic designers and students in other disciplines, as well as intercultural design, stresses
collaborative approaches and aids in graphic design research. Other strengths include the building of research into curricula, adaptation from other disciplines, and the focus on socially conscious and ethical concerns for graphic designers.

The study had factors creating limitations that, if addressed in further studies, could enhance further exploration of the study’s subject. The study’s sample for the survey portion was small compared to the scope of graphic design educators in the United States. Around 1,200 email invitations were sent, with a return of 131 responses, a 10.9% response rate. The time frame for the study was limited by academic requirements and scheduling. Additional time for data collection for the survey would give a longer period for responding and improve response rate. Collaboration with organizations with regular communications and specific communications to design educators would also broaden the study’s sample.

Additional interviews with a broader range of institutions and programs would deepen the conversation and bring to light more techniques and programs being utilized in graphic design education. A panel created of the existing interviewees would galvanize the ideas and methodologies brought up individually within the interviews. Focus groups or interviews with students of these educators would round out the discussion with another viewpoint of the system.

Conclusion

The state of undergraduate graphic design programs is at a turning point, and graphic design research is at its crux. The discipline has opportunities to refine and confirm the terminology and objectives for the specification of research methodologies, description of theories, and establishment of nomenclature to support the transformation in the education and practice of graphic design.

Recommendations developed through this study include the validation of nomenclature used in graphic design research; the sharing of knowledge between design educators through graphic design research-specific organizations and conferences, increased publications in scholarly journals and the development of an American design research organization like those found outside of the United States; increased dialogue collaboration, both within the discipline and interdisciplinary; and embedding research into curricula.

Future research is required to track and develop graphic design research, particularly in undergraduate education. The nomenclature and taxonomy of graphic design research that is described in this study is a working foundation for future study. Further interviews would broaden the knowledge base of graphic design research as it is being employed in educational programs, as would focus groups and panels made up of those active in graphic design research and education, as would a qualitative study using data collected from the Proficiencies: Languages and/or Other Extra-Visual Knowledge and Skills of NASAD assessments for accreditation.

Studies of international educational programs would inform the development of the American system. Surveys, focus groups, and interviews with prominent leaders in graphic design...
research would expand the discussion cross-culturally. Most importantly, the open discussion and the study of the development of standards for the discipline is an ongoing process that will need to be followed and recorded.

Author Biography

Madonna Dersch, MFA
Madonna Dersch is a graphic designer whose concentration in graphic design research was driven by her time spent teaching the capstone portfolio course at Virginia State University for students graduating with their BFA degrees in graphic design or visual arts. She aims to further the conversation on preparing students to curate their consumption of research and implement this research into their study and practice.

Dersch holds a Master of Fine Arts (2017) from The Savannah College of art and Design, and a dual Bachelor of Fine Arts in painting and Bachelor of Arts in Art History (1998) from the State University of New York at New Paltz. This paper is based on the thesis of the same name submitted to the faculty of the graphic design department of the Savannah College of Art and Design in partial fulfillment of the requirements for the degree of Master of Fine Arts in Graphic Design and Visual Experience. The full paper may be accessed through MadonnaDersch.com.
Sparking potential ideas of ‘best-fit’ for design work: a conceptual model for research

Marieka Easterley, University of the Sunshine Coast, Queensland, Australia, marieka.easterley@research.usc.edu.au

Abstract

There is considerable interest within the design research domain in the possible cognitive functions and actions as ‘design thinking’ is used. This proposal commences with reference to Senge who suggests, “Truly creative people use the gap between vision and current reality to generate energy for change”. He drew from the musician Fritz, who proposed, “It’s not what the vision is but what the vision does,” (1990, p.153). The imagined ideal in a vision seems to act like a spike setting off self-urging creative intuitions and insights and instinctive reactions. A conceptual series of diagrams will develop these insights where an imagined ideal is to be set up as the vision as the anticipated experience of a ‘best-possible-self’ with success, where emergent ‘ideas-of-best-fit’ closely match the designer’s goals and desires. The triggering mental actions required are similar in form to De Bono’s technique based on ‘Six Colored Hats’ (1985). In this project, however, the practitioner adopts an overarching meaningful ideal for a ‘hat’ in the form of an experiential clear sense of success as motivating ideations emerge, such that these closely match their goals and desires as a ‘best-possible-fit’. The model is also potentially transformative as the visioning ideal could be framed such that any emergent effects of encoded formed bias or a self-limiting psychology could be effectively reduced or eliminated through the applied created differential as a ‘generative gap’ for the self. This paper will further suggest how this envisaged ideal of success could be experientially explored through co-creative action cycles of research in different design-thinking domains.

Keywords: design-thinking cognition, creative visualisation, transformative research, generative futures

Creative and innovative ideas are required at every stage of activities in designing solutions or a possible prototype for a product or service that meets some kind of an ambition or brief. Prior to imagining possible solutions and prototypes, clear insights and judgments are needed in defining the current state of requirements and the possible gap between what is known or available and what could best fulfil the ambitions of the designers and clients. Then, as various imaginings come forth and are considered in turn, further judgments are needed to decide on which ones to adopt and develop, and the best possible pathways of actions to follow in achieving success.

This paper is to develop a conceptual framework for testing through collaborative research that is to be focused on asking the question of whether there is a possible way of effectively sharpening and enhancing the creative and intuitive or judgmental activities the practitioners
The aim is to establish an action-oriented mental model which is based on a vision of a possible best self experiencing success in the ways the practitioner(s) bring forth and determine the very best and most supportive insights and ideas for their designs and their actions, thus successfully meeting their aims and ambitions within the design brief they enact. This paper is being developed using the devised mental model with expectations that the results could be taken up and investigated as a design research activity, both for the individual and the individual in groups within different design-work domains at all levels and scale.

**Literature Review: Conceptual Framework Development**

There is an array of invented design-thinking tools and activities that assist in the process of what Wallas (1926) through to Cross (2011) and others more recently such as Taura and Nagai (2017), refer to as the forms of creativity and related “designerly cognition”, including the application of the further judgmental and selective cognitive activity and knowledge that could be brought into play as the design-work proceeds. Several scholars from the Editorial Board of the International Journal of Design Creativity and Innovation (IJDCI) in 2013, suggested that, “…despite extensive studies of innovation and the introduction of hundreds of tools and techniques that purport to assist in creativity, the topics in general and their role in design in particular are incompletely understood.” (citing McMahon from this Board, p.4).

VanPatter and Pastor from the Humantific organization have offered a close critical analysis of the range of approaches and processes involved in both the “sensemaking” and “changemaking” activities that constitute design-work at four different operational levels (2016). Similarly, albeit with a simpler analysis, Cropley and Cropley (2009) provided a critical exposure of different developed techniques for “generating novelty” and the “critical evaluation” that could be brought into play as the design-work proceeds. These techniques included, “a) reversing the problem, b) considering the end result, c) focusing on the dominant idea, and d) discarding constraints” (p. 216-223). The proposed conceptual framework and model will work with part b) in particular although it could be applied in all forms of the elements constituting design-work activity, and at all of the four levels as VanPatter and Pastor propose.

The conceptual framework for this paper is not concerned with analyzing the different cognitive functions that are brought into play and combined by practitioners in different design phases and contexts. A critique of the literature on research into the various actions that could be brought into action within the cognitive process of “coming to know in the moment” is being developed elsewhere (Easterley, forthcoming). The most important key aspect of relevance to the proposed conceptual framework and model being revealed through this paper is to suggest that the whole range of the possible cognitive functions that designers engage would have a similar triggering generative dynamic at play, as well as a subconscious generic form of an ordering shaping and process that would be brought into action through this dynamic, with the emergent streaming of the results in one’s consciousness then being classified as imaginings or insights, or selective judgments, for instance, accordingly. Similarly, without diving into reviewing the question of whether the agentive source is
considered to be an act of the brain’s neurons or of some kind of an immanent creative intelligence or consciousness, it is considered essential to accept there would be some kind of driving/ guiding and triggering agency as a mechanism behind each kind of designated cognitive action, including the directed human attention and focusing that would be brought into play as the emergent gestalt is then triggered and shaped.

The design phase for this research begins with Figure 1 that shows how the various elements are to be teased apart and considered. This diagram is intended to illustrate the presence of certain triggering dynamics that are likely involved in creating a physical <differential> or spike, which then behaves as the activator to the sparking cognitions and sentience plus actions that follow. It also illustrates how to separate the role of possible factors as filters that are directly responsible for the shaping and ordering of the emergent results.

![Diagram](image)

**Figure 1: Teasing apart the different components in the cognitive functions at play as design-thinking is used**

It is important not to ignore or jump over the essential triggering dynamics that are formed in the shape of a created <differential> or spike. This form of punctuation is used in the same manner in which the symbol for <enter> is used in IT systems analysis and coding: the symbol suggests an initiating and triggering action of energizing activation is being created and set off in the system. This triggering spike as the spark is assumed to also set off the shaped ordered flow of the emergent fired neuronal activity that can be picked up through the brain, as well as the form of the realized ideas and insights the practitioner discerns, both of which are closely correlated in form (e.g. Crick & Koch, 2003). This proposed <differential> thus would also be responsible for triggering the emergent felt urges and hunches as intuitions might form, and perhaps also excite further refinements or reactions of sorts as the intuition is followed. This <differential> seems to behave in the moment or as the design-work develops, much like Maslow’s conception of there being a set of “actualizing potentials” at play within the developing child (1943).

**The Generative Role of a Vision in the Triggering Dynamics**

Much has been done in psychology involving an examination of the seeming automaticity that’s triggered through the setting of personal desires and aims as a goal, and thereby to the
requisite forms of possible self-regulatory behaviours that follow in achieving ambitions (e.g. Baumeister & Voh, 2004; Boekaerts et al, 2000; Gollweitzer, 1993). The proposed conceptual framework for this paper is to connect the idea of a purposive desire and intention that the practitioner brings forth and holds, with the resulting emergence of the shaped ideas and insights they realize and can further develop. A proposed conceptual model from Carver and Scheier (as cited by Carver in Baumeister & Vohs, 2004, p.13-39) suggests the equivalent of a cybernetic system could be brought into play. They likened the shaped form of a goal such that it would act like some kind of an “attractor” to the desired motivations, and the behavioural actions and thoughts, that could lead the practitioner towards satisfying their ambitions and goals.

This notion of there being some kind of triggered creative, energising and motivating action that results from a held desire as a goal, has been picked up by Senge, who drew on the musician and composer, Fritz (1984), to suggest there is a critical importance in the energizing role of a held personal vision, and the creative impetus and power this seems to invoke. Fritz surmised how this works from his experience to suggest, “It’s not what the vision is, it’s what the vision does”. Senge then adds the observation, “Truly creative people use the gap between vision and current reality to generate change [and creative actions for such]” (1990, p.153 with my added interpretation). He proposes:

“...The juxtaposition of vision (what we want) and a clear picture of current reality (where we are relative to what we want) generates... …a ‘creative tension’: a force to bring them together, caused by the natural tendency of tension to seek resolution” (p.142).

Realising the Creative Tension at Play through a ‘Design-Pull’ Psychology

The next step in this model development is inspired through the observable evidence of there being a direct correlating connection between the shaped form of the held goal or an intention and the emergent shaped thoughts that seem to be triggered. This can be seen for instance in the application of De Bono’s ‘Six Thinking Hats’ technique (1985) that relies on the players adopting the meaning that each hat colour suggests, as they bring forth creative ideas and insights for their strategic decisions and actions. So, if the idea of a hat is extended to include the articulated form of a personal goal as a vision of the experienced [Future-Self] with successes, then this could behave like an attractor to the emergent ideas and insights the designers might elicit and use.

Square brackets are to be used in this case to suggest this imagined [could-be] could come into existence as a temporary virtual state for the self that has been created in form.
Figure 2: The structural generative dynamics at play set up at the start through the [could-be] of success.

Figure 2 sets out a possible way of interpreting this close cybernetic relationship that will behave as if the creation of the <differential> is virtual but has a physical impact, as it thereby becomes the activator and the spike to the emergent results. The captured <differential> thus behaves like a spike with an internal behaviour of closure, thus thereby triggering the implicate ordering and shaping of the the realizable gestalt, which the practitioner could feel and discern as this happens— or not.

This deliberate shaped form of the personal action of visioning is to be adopted as the central key component for triggering the potential unfolding actions, decisions and outcomes that could be set off to form as the design-work proceeds. It is critically important to note that this idea of an imagined anticipatory [Could-Be] of experiential success will clearly focus reflective attention on the practitioner and not directly on the nature and form of the eventual designs they produce. Related to this is the understanding that innovative designers have been switching attention to the epistemological position of conducting their design-work through satisfying the potential user-centered experience that could be built into the designs they produce, such as in IT, or the design of solutions they offer to some kind of an unresolved societal problem. In the case of this model being developed, the user(s) are the designers whose ideal future [Could-Be] of experience is one of success, and this then becomes the vision to which they would cleave.

A [Best Possible Self with Success] as the Future Experiential [Could-Be]

The actual form that this imagined [Future-Self] takes is derived from research that began with the emergence of studies based on “salutonic” (Antonovsky, 1987) and “positive psychology” (Seligman & Csikszentmihalyi, 2000) and the various forms of future oriented “possible selves” that seem to motivate ideas and well-being (Markus & Nurius, 1986; Ruvolo & Markus, 1992).
As research into the potential effects of future possible selves advanced, researchers such as King started to work with the notion of a “Best Possible Self” (BPS) as the motivator of well-being and hope (2001). Loveday et al (in press) offers a critical review of the research activity that followed, which has shown it to be a “viable intervention for increasing optimism, positive affect, health and well-being”. Further research in progress from Loveday suggests, “additional outcome variables as hope and appreciation could be added as potentially enhancing efficacy the more the imagined BPS state is activated”.

King’s research activity is based on the subjects writing about their imagined or intuited [Best Possible Selves] in a positive manner. The proposed conceptual framework for this new research project will take this idea a step further by creating an articulated [Could-Be] for the imagined [Best Possible Self] that enjoys the experience of all emergent success. However, instead of just writing about the experience and actions that might be envisaged, the conceptual framework is to be based on switching the personal writing process around such that a script is developed from this future positioning, and written just AS IF the whole range of successful possible design- work experiences have already been realised in the best possible form they could take – even if the practitioner does not yet know just what form that could become.

Potential Effects from Self-Limiting Beliefs and Behaviours in Context

The third step in this constructed framework and model is to offer significant recognition to the importance of the practitioners becoming aware of, and managing, their inherent potentials for bias and other unconscious self-limiting and contextual inhibiting factors at play (e.g. Kahneman 2011). These possible factors are thought to be acting like filters that shape the emergent gestalts. Figure 1 showed where these shaping and ordering filters are placed in the phased flow of the triggered cognitive actions. Now, Figure 3 illustrates how the conceptual framework recognizes and accommodates this requirement, showing the kinds of the individual and contextual filters that could be brought into play in an autopoeitic, systemic and naturalistic fashion, through time.

The proposed conceptual framework and model is to respond to this aspect through the

---

**Figure 3:** The filters and factors that are brought into play through each projected [could-be]……
notion of the imagined and anticipated emergence of a [Best Possible Self] as the potent future [Could-Be] is also experiencing success in identifying and managing any emergent effects of encoded self-limiting old fears or doubts and the adopted related behaviours or trauma, which could interfere with the individual’s potential success. Each practitioner would be advised to adopt a praxis of mindful self-focused reflective activity as their particular thoughts and emotions emerge through each phase of their design-work activity, from focusing in on what Argyris with Schön (1989) suggests should be a “double-loop” process of considering both the organisational and political contextual factors and possible inhibiting limits to what could be possible in their design-work, as well as the possible contributions their own personal factors and bias might be making to the filtering actions that are set off by the spike.

The use of Causal Layered Analysis (CLA) proposed by Inayatullah (as cited in Bussey, 2014) would be a useful reflective technique to also adopt. The role of the [Best Possible Self] as a vision in this proposed new conceptual framework and model is to thus be expanded to include the idea of the anticipated experiential success for the self that is also including the anticipated effects of a potential transformative change that could be invoked through the iterative phases of the design-work activity (and beyond them as well).

**Methodological approach: discussion**

The epistemological positioning for the methodological approach follows from Feast and Melles (2010) who highlight the idea suggested by Cross for research into “design praxiology: the study of practices and processes of design… [as] tactics or strategies” (cited in Feast and Melles, p. 3). In this light, however, instead of using a constructivist stance based on studying the practices of leading designers and creative practitioners, this project aims to design a methodology that is to be pragmatic and grounded in the design-thinking process itself, through engaging with potential collaborative investigators in using an action-oriented and subjective lens for their investigating the application and utility of this proposed conceptual model in practice. The developed ideas and approach would have to involve some form of an iterative cycle of co-creative collaborative investigation and learning through the participants working with an experiential engagement and testing of the proposed framework and model. Guided imagery for the future [Could-Be] along with the use of a personal back-casting process enacted through self-focused script-writing is to be used at the start in establishing the most representative imaginings of a [Best Possible Self] with success in the contributions then made, even though there is no demand for ideas of just what that future state might contain at the start.

Some form of possible pre- and post-interventionist design of such an instrument for testing might be the best method to follow, although the author as chief design research investigator would welcome any alternative ideas and suggestions that could be assessed as a prototype.

Marieka Easterley BSc(Hons); BCom; GDipLib

My background is mixed as I transitioned away from two undergraduate degrees dependent on performance-based learning and began to focus my interests on developing a pragmatic action-oriented philosophy and praxis based on experiential learning and research with the intention of bringing out the very best in myself and in others. The conceptual notion of a self-focused form of an imagined [could-be] that is based on the emergent experiences of a best possible self with the potential for making effective decisions and actions to bring this about, now forms the basis for the current practice-led research and associated educational materials I have designed for this purpose. I am currently in receipt of a highly valued University Postgraduate Student Research Scholarship for the purpose of undertaking a Doctorate of Philosophy at the University of the Sunshine Coast in Queensland, Australia. Conference attendance and co-creative enquiries and learning with design-thinking and futures studies practitioners, where possible, form an exciting key part of the academic life I now live and desire to expand.

I can be contacted at: marieka.easterley@research.usc.edu.au
Using Lego™ Serious Play™ as a teaching method to facilitate understanding of design thinking with non-design students

Bridgette Engeler, Swinburne University, Australia bengeler@swin.edu.au
A Lam Kim, Swinburne University, Australia alamkim@swin.edu.au

While many people are familiar with Lego as a toy associated with imaginative and creative play, the Lego™ Serious Play™ method goes much further and deeper than most activities generally understood as using and playing with Lego bricks. Lego™ Serious Play™ has been used by many organisations, and the method is regarded as beneficial for creative thinking, innovation, team building and strategy development.

Keywords: education, creativity, innovation, design thinking, Lego™ Serious Play™

What is Lego™ Serious Play™?

Lego™ Serious Play™ was initially developed to explore complex problems in a creative way (James 2013, p.1). The Lego™ Serious Play™ method is based on enabling participants to ‘build to think’: participants are asked to build models as 3D representations of their responses to particular questions, posed by a trained facilitator. With specific attention to facilitating easier and deeper engagement, Lego™ Serious Play™ participants use Lego bricks to conceive then visualise their ideas or views about complex issues. The method comprises structured activities (called Application Techniques) specifically aimed at facilitating engagement by enabling the expression and sharing of ideas before discussing different views or understanding.

There are three standard applications of the Lego™ Serious Play™ method: 1) Real Time Identity for You, whose goal is to allow participants to understand themselves and their colleagues better; 2) Real Time strategy for the Team, which aims at unlocking the full potential of a team quickly, effectively, and deeply; and 3) Real Time Strategy for the Enterprise, a process to continuously develop strategies in an unpredictable world. (Frick 2013, p.6)

Over the course of a Lego™ Serious Play™ session, participants develop multiple models in response to a series of questions, specifically-devised to achieve the intention and outcomes of each session. Models can be built individually or in groups. The questions are designed to foster emergent responses and support reflective learning, while fostering deep thinking and discussion. The models are the starting point for individual storytelling; participants apply creativity and imagination to share the narrative of the models they have built, exploring complex ideas and problems and drawing on metaphor and symbolism to uncover hidden ideas and issues. Each participant’s perspective and ideas are shared as part of the process, ensuring
every voice is heard and all perspectives are explained by the model.

The Lego™ Serious Play™ method is influenced by Piaget’s theory of constructivism, which proposed that knowledge is constructed around experience of having interaction with the world and people (Ackermann 2001). This approach shares similar characteristics with the theory of experiential learning (Kolb 1984). In other words, ‘experience’ plays an important role in the process of Lego™ Serious Play™; experience is mainly derived from building individual models and sharing a story of individual models. Combined with Papert’s constructionism, or learning by making, Lego™ Serious Play™ frees participants to explore ideas and develop them more fully in real time. Both Piaget and Papert believed that individuals make meaning and that learning is facilitated by constructing actual artifacts or objects that can be shared and discussed with others (Ackermann 2001).

Relevance of using Lego™ Serious Play™ in the process of design thinking

Design thinking is sought out for innovation and as a way of shifting organisations from an overreliance on analytical thinking to abductive thinking and reasoning (Martin 2009). It can be split into two parts: design, the process; and thinking, the intellect or intelligence that occurs at each stage (Ambrose 2010). Sometime used interchangeable with the process of human-centred design, design thinking is a broadly-understood term and methodology for innovation, creation and enablement not the art and craft of designing or a substitute for professional design (Ambrose 2010; Brown 2009; Lockwood 2009).

Increasingly it is brought into discussion and use with non-designers and more traditionally- oriented business people as a value model for differentiation, integration and transformation (Lockwood 2009) and as a means to explore ‘wicked problems’, accelerate innovation and increase efficiency (Brown 2009; Martin 2009).

This paper explores the integration of Lego™ Serious Play™ in a multidisciplinary unit that focuses on teaching design thinking to non-design students as part of a postgraduate unit focusing on creativity, innovation and design. The authors chose to introduce the Lego™ Serious Play™ method in classes in Semester 1, 2016, followed by further classes in Semester 2 2016 and Semester 1, 2017.

Use of Lego™ Serious Play™ in multidisciplinary class environments

The Lego™ Serious Play™ method is used in a multidisciplinary unit that was structured to provide students with both individual and activities and assessment tasks. Given the typical characteristics and challenges of working environments using design thinking, Lego™ Serious Play™ was integrated into the curriculum design to foster collaboration, support better teamwork, and encourage students to have more confidence about being creative. Our assumptions were that Lego™ Serious Play™ would catalyse social bonding and collaboration while challenging students’ comfort zones and motivating creative thinking. Given the multidisciplinary background of students (who are predominantly enrolled in business, human resources, management, marketing, entrepreneurship, engineering, media,
communications, health and sociology) it is essential to enhance students’ skills, knowledge and confidence in these areas, and ready them for immersion into the theories, tools and methods of design thinking.

Characteristics of multidisciplinary students
Students from disciplines not usually considered ‘creative’ may not perceive themselves as being creative (Bateson 2013). Students in the unit discussed in this paper begin with little or no knowledge or experience of design thinking nor its demands of collaboration and teamwork. While the majority of students often claim themselves to not be creative, over time this perception and categorisation can change. Other common patterns of ‘non-creative’ students are:

- Fear about sketching or visualising their ideas
- Prefer linear process
- Prefer well-defined problems
- Unfamiliar with iteration
- Shallow mindset about understanding end users
- Solution-focused thinking
- Technology-driven thinking
- Difficulty in understanding a big picture

Behaviour changes throughout a set of activities
In addition to the design thinking tools, methods and theory covered in the unit curriculum design, the Lego™ Serious Play™ method developed was specifically adopted to facilitate social bounding and story building with the use of their imagination. A set of structured activities for specific classes in the semester-long schedule is summarised in the following table.

<table>
<thead>
<tr>
<th>Activities/Tasks</th>
<th>Purposes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tower building</td>
<td>Introductory session to give a chance to be familiar with building and story sharing as well as experience to deal with an unexpected challenge throughout the process</td>
</tr>
<tr>
<td>Building a model for group work</td>
<td>Understanding core principles that affect to group work</td>
</tr>
<tr>
<td>Connecting the models</td>
<td>Connecting individual model that presents specific principles of group work to create a strategy for group work</td>
</tr>
<tr>
<td>Building a model that represents themselves</td>
<td>Critically review their strengths and weaknesses in terms of personality, skills and knowledge</td>
</tr>
<tr>
<td>Adoption of the model into the group strategy</td>
<td>Discuss individual contribution and capabilities in relation to the core principles of group strategy</td>
</tr>
</tbody>
</table>
One of our key assumptions was that the use of Lego Serious Play would be beneficial in building social bounding and facilitating new way of thinking.

a. Understanding different perspectives and themselves
The comprehension of different perspectives is one of the core principles of design thinking (Buchanan, Liedtka & Ogilvie). We often hear how ‘empathy’ plays an important role in the design thinking process. However, it becomes a challenge for some people to have genuine understanding of others, especially for non-design students. The intention was to use the Lego Serious Play method as a starting for team formation and establishing group dynamics including ground rules for communication and collaboration. It is also expected that the Lego Serious Play method used in group problem-based learning projects could help with the challenge of developing empathy or ‘putting yourself in someone’s shoes’.

Through a number of designed Lego Serious Play activities, students would have various chances to hear others’ perceptions, interpretations and experiences of specific subjects or situations, and this would therefore help them to truly understand different perspectives. This draws on James(2013) study that indicated the benefit of using Lego Serious Play for social bounding and facilitating engagement.

At the same time, the use of Lego Serious Play gives students a greater chance of understanding themselves. Throughout the structured activities, students are able to review their strengths and weaknesses in relation to their personal characteristics, skills and knowledge.
Having a better understanding of themselves can result in improved management of individual contribution and performance in advance. This would lead to opportunities to discuss how to collaborate and combine different skills and knowledge, in order to eliminate weaknesses of team members by setting a strategy for their team projects. Unlike the traditional group discussion that is often controlled by more vocal students, with Lego Serious Play every member of a team is required to discuss and participate in the process of creating their team strategy and ground rules. In addition, communication between team members tends to be clearer, as they visualise their thoughts and ideas in a 3D model format. This is perceived as specifically beneficial for students who have language barriers and face challenges with verbal and oral communication.

b. Reflection and imagination
Although the structure of a Lego Serious Play session may not be specifically focused on individual team projects, the teambuilding process offers students a chance to rapidly review and reflect on what they do and how to improve for future experiences. There is a clear connection here to the well-known frameworks in the field of design; ‘Reflection-in-action’ and ‘Reflection-on-action’ as indicated by Schon (1983). In addition, students can be continuously encouraged to use and develop their imagination and creativity throughout the Lego Serious Play activities. Based on the research of using Lego Serious Play in organisations, it can be assumed that students who might ordinarily hesitate to share their thoughts and experiences or their views on possible problems and solutions, can use Lego models to create and share stories thereby minimising or eliminating the fear of sharing the output of their creativity and imagination. This experience can be helpful for students in
building confidence when they generate ideas for their team projects.

Establishing a connection between design thinking and Lego™ Serious Play™

As indicated above, the adoption of Lego™ Serious Play™ helps provide non-design students with more and varied ways to practice the following areas:

- Understanding different perspectives
- Active engagement
- Sharing their ideas
- Using their imagination to explain their models
- Reflection-in-action and Reflection-on-action
- Visualisation of ideas

Integrating Lego™ Serious Play™ into teaching and learning activities is a way of introducing all students but especially those from a non-design background to creative activities so they understand that ‘creativity’ is not just ‘creative arts’. It can also enable positive behaviour changes and improvement in the areas listed above, which are core principles of design thinking. Further, students directly engage with imagination and storytelling as fundamental principles of Lego™ Serious Play™ which reinforces the relevance of those skills (over traditional ways) of thinking and solving problems.

Sacred Vs. Modern
Design A Case from Iraq
Shubber Falah, University of Cincinnati, Cincinnati, USA, falahsm@mail.uc.edu

Abstract:
This project is being built on the site of a thousand-year-old mosque, one of five sacred places in Iraq. People visit the place to pray, not simply because it is an old mosque, but rather because they think that the last descendant of the Prophet Mohammed will eventually be resurrected with Jesus Christ and will pray there. In 2006, an architect was hired to design the building. The premises were: 1) the design should promote the concept of sacredness, 2) this project should show belonging to the society, and 3) it should last for centuries. The results were controversial, however, by the time it was revealed to the public, the foundations had already been casted, in the hopes that people would eventually accept it. On the contrary, visitors and pilgrims became upset and began to protest the design. The construction process was thus halted in 2008, and we were hired to utilize the same foundations for a new design, one that fitted with the pilgrims' notions of “sacredness”. We began the project by surveying people’s ideas about what mosques on “holy” sites might look like, determining what a “sacred” place meant to them, and why some places are “sacred.” We discovered that most people think that “sacred” places should seem old. They also singled out some “sacred” examples for us. All these examples have one characteristic: the all hide “a certain kind of mystery”. We studied those examples and then developed our proposal, it was approved in 2011 and will be opened for public in 2018.

Keywords: Islamic architecture, sacred, and Modern.

Background
Islam is divided into two major sects: Shia and Sunni. One major subsect of the Shia doctrine celebrates twelve descendants of the Prophet Muhammed and so is called Twelvers. Most of the Shia Twelvers live in Iraq and Iran. Twelvers build, geld, and glorify the tombs of those “holy” descendants. The twelfth and last of these imams, Al Mahdi (the Guided one) miraculously ‘disappeared’ in Iraq, about 1000 years ago. Shia believe that he is still alive, but cannot be seen physically, God hid him in order to preserve his life. He is called the “absent” or the “hidden” Imam, and so has no tomb. He is expected to return someday to lead the community and achieve divine justice. Shia believe that with his second coming there will be a reign of justice until the return of Jesus, at which time the world will end. Shia think that he will be resurrected from Al- Sahla Mosqu, so they visit it frequently. As such the mosque became a pilgrims attraction.
Rediscovering the Old:

We began the design by surveying people’s ideas and thoughts about what a mosque on a holy site should look like, ascertaining what a “sacred” place meant to them, and why some places are or are not “sacred.” We discovered that most people think that “sacred” places should promote an old architectural test and highlight the idea that “there is one just and almighty God for all people.” Besides that, they singled out some “sacred” examples for us. It turned out that all these examples have one feature: a certain kind of mystery. Most of the offered examples were shrines for the Prophet Mohammed’s descendants; Iraq has four of these shrines. One of the surprising realizations that came out of that survey was that people who revere such places do not distinguish between the architectures of those shrines and the Prophet Mohammed’s decedents themselves, who were buried underneath. We do not know why this is the case, but keep in mind that Islam does not permit the picturing or sculpturing of “sacred” people. As such, people have no idea what the Prophet Mohammed or his descendants looked like, and so perhaps the buildings are the closest thing to them. To conceder all the above in a new design is challenging, because, Iraqi universities were based on a Western model that embraces creativity and novelty in architecture. For example, in the Department of Architecture at the University of Technology in Baghdad, we had always been taught to innovate and look for uniqueness; while copying and mimicking were undesirable.

So there were two choices, either copy the other “sacred” places and avoid criticism, or introduce a new design that blends the notion of sacredness with novelty and be ready for criticism. Yet, in any way, the design should resonate some of the old architectural designs of the Iraqi “sacred” places, and that because of the blurred conceptualization for the architecture and the “holy names” of people that associated with it.

Whilst we had seen and studied old Islamic architecture previously, we had never worked with it, and thus we had to develop our knowledge in this field. We studied a fundamental element in the old Islamic architecture, which was a bat-like vault; it was predominantly used in those
The problem was that there were no professionals that know how to build this kind of architecture any more, except in Iran. So we went to the field, measuring and sketching old architectural shrines to find out how this part works. By using three dimensional modeling software, we have succeeded to develop an architectural prototype; however, there was still one difference from the old architecture. In the old genuine Islamic architecture and traditional methods of construction, structuring a building depended on only compression force analysis because they simply had no steel to reinforce the structure. As such, what are now called “architectural Islamic elements,” such as the four-center arches, a bat-like vaults, or domes were actually structural required elements, as well as part of the architectural design. The problem with our prototype that we have no good experts to build this bat-like vault as a structural architectural element, so it was mounted on a reinforced concrete structure.

Toshimasa Yamanaka, University of Tsukuba, Faculty of arts and Design, Tsukuba, Japan, tyam@geijutsu.tsukuba.ac.jp

Abstract

Different associations are important for regulating and promoting good practices of sustainable product development. On the case of children products, there are many considerations to take, such as mental and physical development or safety. Knowing this broad challenge, how can associations better aid on the development of Design Guidelines for children? In Japan, the country’s context and challenges have led to the development of the Kids Design Association, or KDA, a Non-Profit organization dedicated on the achievement of three missions: “Contribute to children’s safety”; “Develop children’s capabilities, encouraging creativity and sensitivity”; and “Support caregivers during pregnancy, birth and child raising”. Based on an investigation period, the following paper is a case study of the Kids Design Association, exposing its story, goals, relation with society, growth, and performed activities, especially the “Kids Design Award”, a commendation program for acknowledging design practices that takes children needs and standpoints in consideration. We aimed to observe design trends and challenges regarding both Japanese Society and the association. As results, although some of the procedures are oriented exclusively for Japan, we found that the KDA approach could effectively bridge companies with academic knowledge and social demands.

Keywords: Non-Profit organization, Design guidelines, Children, Industry, Society, Japan.

Evident since the 19th century, Industrial associations play a role for regulating and promoting good practices for the sustainable development of products. According to Dimaggio & Powell (1983) they are pressure agents that define socially acceptable conduct to firms in the same organizational field and that tend to cause firms to exhibit similar practices and activities. More focused on the social causes, however, nonprofit organizations (NPO) are organizations that are formed by a group of people in order “to pursue a common not-for-profit goal” (Hartigan, 2006). A NPO is often dedicated to furthering a social cause or advocate a point of view.

Considering the range of fields where industrial and NPO associations act, this paper initially focused on the children’s products and services, on how they are regulated and which
guidelines they may have. Children differ from grownups as they have special development needs that are constantly changing and affecting their ways of understanding the world (Hughes, 2009).

Therefore, children-oriented associations must dedicate special attention for their needs and healthy development. When we looked at children-related associations around the world, we categorized three main types of associations:

- **Policy making**: develops policies to improve children lives, ensure their rights and space in society (e.g. Kids Right Foundation, US, 2003; Association for Young Children Europe, 2012);
- **Industrial**: Focus on strengthening markets for children-related products and services (e.g. Japan Toy Association, 1967, Federation of the European Play Industry, 2013);
- **Design related**: focus on awarding products related with the industry or trade fairs (e.g. Kind & Jugend Kids Design Award, Germany, 2016) or on spreading design-based knowledge to children (e.g. Kids Design Collaborative, US, 2014).

Having a broad series of goals regarding children, their relationship with products, environment, and society, we found a Japanese organization named ‘Kids Design Association’ (KDA, 2017) to have a unique actuation model. Founded on 2006 as an association of companies, doctors, and research institutes, KDA is a Non-Profit organization aimed to stay in the center of industrial interest, social demands, policy making, and design regulations, finding on that position a possibility to mediate interests and contribute to a better future for children. This is represented through the Kids Design Award, an awarding process that recognizes products and services of all natures, as long as they are created while considering children’s needs or standpoints.

On this paper, we are going to perform an investigative case study of the Kids Design Association and their awarding process. While considering that KDA was instituted with Japanese society in mind, we are questioning if its model can be applicable and beneficial to different societies around the world.

**Research Methods**

The current research intended to investigate the Kids Design Association model, history, goals, relationship with society and activities. For achieving this analysis, we performed a case study of the association. As according to Yin (2015), Case studies are considered adequate in situations where the available knowledge regarding a study topic is limited, requiring in depth investigations about the phenomenon in its own environments. Since the association action model is notably different from other found children associations, a thoughtful investigation of its model was necessary.

Due to the importance of the Kids Design award for the association, this paper will be divided in two main parts. The first part will introduce the association history and discuss its relationship with Japanese Society. Afterwards it will investigate the Kids Design Award
processes and reports. Based on an experience period, we gathered data through three main sources:

- Available institutional material of the association and its activities on the past 3 years, including flyers, year reports, awarded products books, developed researches and design tools. The materials were carefully translated from Japanese to English language;
- Semi-structured Interviews with association members; and
- Direct observation of the Kids Design Award 2016 and 2017, analyzing the submission and evaluation processes, as well as the awards and reports.

Kids Design Association - History and Goals

“The kids design Association is a non-profit organization (NPO) aimed to contribute on creating a social environment that leads to the healthy growth and development of children, who make up the next generation” (Kids Design Association, 2017). The association is supported by members consisting of varied companies, organizations, research institutes, and local governments, with a small secretariat office conducting activities that widely publicize and disseminate the following three design missions:

- Contribute to children’s safety;
- Develop children’s capabilities, encouraging creativity and sensitivity;
- Support caregivers during pregnancy, birth and child raising.

Founded on 2006, KDA started as an association of companies, doctors, and research groups, who observed an increase in accidents involving infants. With the most impactful case happening on 2004, when one infant was involved in an automatic revolving door accident (Japan Times, 2004). They observed that most of these accidents often happened because the environment was not suitable or didn’t take children into consideration on their designs. Observable on table 1, and being this a matter of public interest, the situation gave importance for the association foundation, supporting its first Design mission “Contribute to children’s safety”. This mission is not limited to children-related products, but focuses on universal design and accessibility notions, encouraging designs that considers the possible use of children, remaining safe for everyone to use.

According to the Japan Toy Association (2017), More than 80 percent of Japanese customers focus on product safety when buying a toy. However, another buying criteria include promoting the child’s mental and educational development. This perception of how products can affect positively children’s development influenced the association’s second design mission “Develop children’s capabilities, encouraging creativity and sensitivity”. Under this mission, the association seeks not only products but also services that can be educative or allow children to explore possibilities such as toys, games or workshops.

Before the association establishment, on 2005, Japan faced its first decrease of birthrate, a problem that is still one of the country’s main challenges for the future (Japan Times, 2016). Faced with that, the association established its third design mission “Support caregivers during pregnancy, birth and child raising”. Under this mission, the association seeks to encourage the creation of products, services, policies or social systems that can ease the task of raising children, such as the establishment of nursing centers and better policies for work life and parenthood.

As Japanese society advances and face new challenges, we can see that the weight given to each of its 3 design missions are constantly changing. Below we can look on the association newest manifesto, released on 2017:

Kids Design Association sense society’s movement to provide open innovation with all types of stakeholders and make our future continuous and bright. Under our three missions, we intend to:

- Help balancing parenting and work, to accomplish a joyful parenthood experience;
- Take actions for enriching the parent’s time spent with children;
- Make the access of the information about parenting easier and more understandable;
- Make a better environment for parents to spend time with your children outside home, wherever and whenever they go;
- Design environments for parents to share experience and communicate with each other;
- Promote the importance of communities that supports parenting;
- Increase opportunities for local youth and elders to interact with children;
- Research, develop, and apply changes regarding play and learning;
- Create opportunities for children to voluntarily and continuously experience more;
- Try our best to reduce accidents involving children to zero.”

By observing the association’s manifesto, we can see how the balance developed from its 3 original missions. With birth rate being a grave issue for the country today, the first 7 items of the list regard the caregiver’s third mission, followed by 2 compromises related with the “develop children capabilities” mission and only one item dedicated to “Children safety”. One explanation comes from the establishment of the Child Safety Through Design on 2013, that is strictly focused on researching and regulating safe products for children, leaving the main branch to focus on the other missions. Co-relating significant happenings in Japan such as 2011’s Tohoku earthquake, Table 2 illustrates KDA’s changes throughout its history. From the table, we can consider how the associations keeps alignment with social, economic and
political changes.

KDA Network and Social roles

As a Non-Profit Organization, Kids Design Association is supported by 106 active members. When we look at the association members’ growth on figure 1, we notice a big increase from 35 to 95 members between 2006 and 2008, followed by an eventual reduction and stagnation from 2009, ending 2013 with 91 members. This coincides with 2008’ Japan’s economic recession (Volmmer & Bebenroth, 2010) and the great Tohoku earthquake incident in 2011, that affected public interest on children related matters. From 2014, the association restarted to steadily grow, where we can correlate that with an increase in public relations investments and an increased support from the country’s government, who established new ministry awards.
Among those 106 members, 63 are companies, 24 are local governments, and 17 are Research institutes. In contrast, the Japanese Toy association has 197 associated members, being 186 companies, 8 cooperatives and 3 other associations (Japan Toy Association, 2017). While JTA has a bigger network, KDA displays more versality, as most of its associated companies, for example, are not exclusively dedicated for children but product developers or service providers on a larger scale to society such as Panasonic, Mitsubishi, or Tokyo Construction Co. The research institutes act as advisers and observers, analyzing and providing beneficial research data for the association. Among them we find the Japan Pediatric Society, Japan Industrial Designer’s Association, Tokyo Gakugei University, and the Ministry of Economy, Trade and Industry. Finally, the connection with 14 of the 47 local governments of Japan establishes a channel with social demands, also providing chances for direct policy-related interventions regarding children. On figure 2, we can see KDA associated prefectures around Japan.

By taking in consideration those different members and advisors, KDA aims to take a central role between their spheres, mediating interests and acquiring
knowledges to improve the quality of children’s lives. According to the association, this would be a position that bridges the gap between industries, research, and costumers, always taking children in consideration. Also, as seen on figure 3, the association expects that, with this relationship established, they can provide a smarter future for children. A recent action plan, however, puts the children as the center of these spheres, with the association providing communication between different stakeholders.

![Figure 3: KDA social role model](image)

**Organizational structure and project sections**

Kids Design Association consists of corporate members of a wide range of industries, local government members, research institutions and related organizations. Better visualized on figure 4 below, General assemblies are regular held once a year by corporate members, possibly involving more members on different times of the year, given extraordinary situations. Led by the association’s chairperson, the board plays a central role in the organization, discussing and deciding important matters such as the budget and activity policy. The board forward the desired activities to be promoted by project teams and working groups organized into three directly supervised sections: Research and Development (R&D); Awards; and Public relations. A fourth separate section, overviewed by a secretariat, is responsible directly for safety certifications, denominated Child Safety through Design. Below is a description of these four sections.
• Award activities – Kids Design award: Better described on the following section, KDA is a commendation program based on the three Kids Design missions.

• Certification activities - CSD: Founded in 2013, the Child safety through design (CSD) is a certification program for products safety. It certificates products that takes in consideration past related and similar accidents, or information regarding unsafe incidents that have happened on society.

• Research and Development: Through the research institutes, companies, and local government members, the KDA association conducts researches based on their 3 design Missions. The research results are reflected both in the association’s processes, as well as on guidelines or design tools available to the public. Currently under restructuring.

• Public Relation Activities: Exhibitions and workshop events of awarded submissions. The association proactively spreads / promotes Kids Design guidelines through forums, symposium, and websites.

While each of this section needs a dedicated research, we focused our current research on the Kids Design Award.

Kids Design Award

The Kids Design Award is a commendation program for performing and promoting the three Kids Design Missions. Not limited to children-dedicated products or services such as toys, this award welcomes a wide range of products, facilities, programs, and research activities for children and adults, as long they make considerations regarding children usage. While the award started as an independent process of the board members, on the past years it has been receiving increased government support. Today there are a total of 9 minister awards and special awards such as the “Reconstruction Assistance Design”, to support disaster affected areas. Other incentive awards are given by the association and, As KDA grows by listening to social demands, new awards can still surge. Table 3 below illustrate all current awards.

Kids Design Award (Passed Secondary Screening Selection)
KDA Submission Process and merits

The submission process for KDA is not different from general Design Competition processes. On the first submission stage, only digital files are necessary. All the procedure is done online, where the interested party needs to download a preparation sheet, select a desired department and category, input personal information, and prepare documents for submission. The documents must contain at least one main image and two sub-images that explain the context, features, usage, or which of three design missions is the submission focus.

When we look at the merit points for submitters, asides from getting a minister commendation, we see a focus on product advertisement and commendation. among them, publications on Japanese medias, permission to use Kids Design mark on commercials and packaging design; and exhibitions through workshops and seminars. Currently the award has 5 main categories:

- **Products**: wide range of product that takes children of any age into consideration.
- **Architecture**: Spaces dedicated for children such as nursing houses, or considerations regarding Environmental Universal Design.
- **Communication**: Services, systems or workshops related with children;
- **Researches**: researches with a focus on children, their needs, products and services;
- **Reconstruction Assistance**: Submissions focused on supporting disaster-affected areas such as Tohoku’s earthquake affected region.

KDA Evaluation Process

Initially each online submission validity is verified by the association’s secretariat. The secretariat checks if all the documents are in order, if it took children consideration on its design, if it’s a recent design, and if it is not a repeated submission from previous years. If everything is in order, the secretariat will ask for additional materials, such as products, videos, or mockups, as well as the submission fee payment of 50.000 yens (around 450 US Dollars).

For the evaluation, specific days are decided for each of the five categories. On these days, independent evaluation committees will be formed composed of professors, doctors or field experts. The secretariat become assistants to the evaluators, supplying them with additional data about each submission, as well as comparing with previous years entrees to check for originality. Acting more as guidelines than decisive factors, the evaluators rate the following 4-point scale:

- Usability, Functionality, Manipulation;
- Viability and benefits to society;
- Originality, creativity, and innovation;
- Overall Aesthetics, Design, usage of colors, and shape.
Each evaluation is followed by general comments from evaluators, who will decide between awarding or not the entree. Depending on the submission’s qualities, they are awarded by the association, passing to a third and final evaluation to decide the minister’s awards. This evaluation is performed collectively taking the evaluators’ reviews, the association’s considerations, and the ministers’ social demands. With a direct commendation from the prime minister, the minister awards are announced through a ceremony. From this stage on, exhibitions of the awarded products take place on prefectures around Japan.

**Kids Design Submission Reports**

From 2006 to 2017 the Kids Design Award received a total of 4,081 applications, and awarded 2,453 submissions. Observing the changes between submissions provides a way to understand the association growth and challenges, as well as to observe trends in the Japanese industry. On figure 5, we can see the number of submissions and awards from the year 2006 to 2016, as well as the proportion rate between them. By observing the submission numbers, we see a steady growth from 2006 to 2010, followed by a decrease in applications, possibly due to the earthquake disaster impact on the country. The submissions started to grow again on the following years, although the year 2017 started with a new decrease in submissions, which will require further observation. The award percentage rate increased from 42% to around 60% on the following years, with us assuming an increase in the submissions quality, more than a loosening of evaluation criteria. In theory, all products can be awarded, if they achieve the required quality.

![Figure 5 – KDA submissions and awards on the left and Award percentage on the right](image)

By observing the application submissions through the five categories and three design missions we can look on possible trends for the Japanese Society. On Table 3 below, we can observe 2017 and 2016 submissions by category, with only the ‘product’ category having increases. Among the three missions, “Develop children’s capabilities, encouraging creativity and sensitivity” received the most applications. Due to the institution of the safety evaluation section (CSD), the need for applications focused on
safety has been decreasing, however, as the government is pressing for solutions that can increase birth rate in Japan. Submissions focused on “Support caregivers during pregnancy, birth and child raising” should be increasing instead.

</tbody>
</table>

Another negative trend is the drastic reduction on Researches submissions, indicating that the association is not managing to draw the interest of academic researchers. Many explanations can come for this trend. One explanation is the lack of academic repercussion, since KDA is not a journal or a conference. Regardless, academic support can be vital and this matter should be better taken in consideration for future awards. The category “Reconstruction Assistance” has also been receiving less submissions, however, since it has already been 6 years since the Tohoku earthquake, this program is already expected to reduce activity.

**Considerations**

Kids Design Association is a unique organization that is not quite an industrial, design, medical, research, or even political, but, as a non-profit organization, something in between. Aiming to mediate these different stakeholders, the association intends to promote a better environment and future for children. This model has been proving successful as the association has been growing while attending to Japanese society demands and by achieving government support.

Throughout its history, KDA has also been keeping faithful to its three design missions “Contribute to children’s safety”, “Develop children’s capabilities, encouraging creativity and sensitivity”, and “Support caregivers during pregnancy, birth and child raising”. However, as Japanese society has been developing, we see an expanded focus on its last goal as to increase birth rate in the country. As seen on the number of submissions for this category on the kids design award, this matter remains a challenge to be faced by both the association and Japanese society. Analyses of the Award submissions also pointed that the association is having difficulties in getting research submissions. This can turn to be a limitation, since KDA should use the support of the academia to better mediate the interests of industry and society.

Another possible limitation for the association’s growth is that, by focusing on Japanese society’s demands, KDA may be lacking internationalization, not communicating or aligning with international associations advancements, issues or trends. Language still presents a big barrier for Japanese associations, with only a few information available in English. However,
this factor also contributed into making KDA organization model unique and worth exploring. We hope that, on the future, more openings for internationalization and discussion arise for Kids Design Association, so that its model can better develop and contribute for the institution and development of children-dedicated associations around the world.

Acknowledgments

We are deeply grateful for the Kids Design Association, who granted us access to research materials and gave full support during the entirety of this process.

Abstract

The growing speed with which consumers discard artifacts is a significant but regrettable part of the capitalist economy. High consumption rates are accelerated by contemporary society, which is based on a model of values that link the notion of well-being to profit generation and consumption of material goods. This exacerbated consumption cycle perpetuates environmental damage. In this context, proposing sustainable solutions involves new ways of thinking and doing that are distant from the practices of the current model of consumer society. This paper reflects on the necessity to implement changes into the design process, production, and consumption modalities. These changes propose a “new” role for designers as professionals, and as individuals in society at large. This research connects the concepts of metadesign and open design—enabling system awareness. Metadesign can be considered critical and reflexive thinking about the boundaries and scope of design, but also, as the prefix “meta” implies, it can be understood as the design of the design process, in a critical and reflective way. Open design implies the openness of the design project for multiple actors (including consumers), information sharing, and building knowledge between them. As a result, design can lead to consumption modalities situated in slow culture, transforming the relationship between users and artifacts.

Keywords: open design, metadesign, ecosystems, users, consumption.

Consumption is part of human behavior. However, it is clear that society and culture influence consumption, in relation to values, beliefs, and meanings. Therefore, design and other fields, like media, are related to the creation of meaning, and in this context, humans are most often seen only as consumers. As consequence, society is organized in relation to consumption, which can be either tangible or intangible.

Conspicuous consumption, a term coined by Veblen in 1899, remains a relevant way to understand the current forms of consumption, which are related to the consumption of symbolic values of objects in an attempt to furnish social identity. However, postmodern identities are not only based on class identity as described by Veblen (and others like Simmel and Bourdieu), but also on personal identity (Svenden, 2006). To create and develop their own personal identity, consumers adopt and appropriate products to define themselves (i.e. clothes, cars, cellphone).
This appropriation allows people to communicate their opinions, but also to experiment with different selves. The desire to show and make explicit their identity is influenced by fashion. In this sense, fashion is more a process than an object and entails “[…] the conjunction of two logical systems: the system of ephemera and the system of aesthetic fantasy” (Lipovetsky, 1994, p.25). Ephemeral is one of many adjectives associated with the current mode of consumption that is influenced by fashion. The fast turnover is a combination of just-in-time production, and the high volume of consumption that is associated with the capitalist economy. Therefore, a model of values that link the notion of well-being to profit generation and consumption of material goods, accelerates the speed with which consumers discard artifacts. The exacerbated consumption cycle perpetuates environmental damage.

The connection between the rise of consumption and design has been a topic for discussing among different researchers and critics. Papanek (1971) provided an in-depth critique of the design profession, pointing out its role in encouraging consumption and therefore contributing to ecological and social degradation. Although design can play an important role in changing this situation by proposing sustainable solutions, it is necessary to implement new ways of thinking about the ecosystem in which design is part – which is beyond the idea of the design process focused on achieving an expected solution to satisfy user’s needs.

**New ways of thinking**

Design projects are intrinsically connected to the ecosystem in which they are involved. Therefore, every decision in the design process has a consequence which affects not only the design process, but also all entities that are part of this ecosystem, and the proper ecosystem itself. In this perspective, objects can be considered all human and nonhuman elements (*i.e.* technology) that have any kind of interaction (c.f. Latour, 1996).

The design effects in the ecosystem and its entities make responsibility a complex action which is more than just good design choices, since it is also related to transparency, commitment and attention to the consequences of any design action. Therefore, design should reconsider waste and the speed of the consumption lifecycle. New product life cycle and new forms of consumption can be related to the openness of the design process, in which it is understood that the designers are not the only creators, but that they work in collaboration in open projects, together with users, other consumers, and a multidisciplinary ecosystem. The input of the design is the facilitation, and the collaboration is the creation of a reasonable space expressed in the form of patterns, prototypes, tools, space for conversation. This model represents a new paradigm for design.

In order to achieve this paradigm change, it is necessary to accomplish a mindset transformation, in which design practice and methods should enable people to have a different relationship to the artifacts, reducing the waste life-cycle. Our position is that open design practices can be a way to engage users in a participatory process, prompting a reflective critique about consumption.

**Open (Meta) Design**
From the moment that design starts to take into consideration all entities, and the complexity of different interactions and their connectivity in the ecosystem with which it is involved, new forms of design practices arise – like open design. Although open design is not a new practice, it changes some of the current paradigms of design practice, like authorship, the use of human centered design and the idea that every design project should end with a material outcome, such as a product or a service. However, one of the most important changes is the role of the designer.

The development of open design is connected to the rise of computers and the internet, just like other fields influenced by the open movement, such as open source software, open science, and open technology (De Mul, 2011). The introduction of digital technologies has enabled new forms of organization and distribution of resources, or it has modified obsolete forms (Goetz, 2003). Therefore, new spaces and conditions for practice are developed regarding the openness of projects, participatory practices, the sharing of knowledge and information, and collaborative interactions.

Open design is more than just a new way to create products. As a process, and as a culture, open design also changes relationships among the people who make, use and look after things (Van Abel, 2011). Since open design breaks the boundaries between different entities, it is possible for non-designers to become “designers”, allowing end users to share projects and access to digital fabrication technologies to manufacture the products they want locally (Menichinelli, 2016; Stappers, Visser, Kistemaker, 2011). Therefore, open design favors the development of new forms of value, expanding existing relationships, power and responsibilities between suppliers, consumers, and competitors in a given ecosystem.

From this perspective, the designer has to become a metadesigner, shaping environments in which unskilled users can design their own objects. The metadesigner resembles the scientist who no longer creates a linear argument, but instead develops a model or simulation that enables the user to explore and analyze a particular domain of reality, or a successful game designer who designs a game space that facilitates meaningful and enjoyable play (De Mul, 2011).

According to the Merriam-Webster online dictionary, the prefix Meta is “usually used with the name of a discipline to designate a new but related discipline designed to deal critically with the original one (i.e. metamathematics).” Regarding the idea of thinking and/or reflecting critically about the discipline, metadesign can be considered critical and reflexive thinking about the boundaries and scope of design, aimed at coping with the complexity of natural human interaction made tangible by technology, with the goal of transforming this complexity into an opportunity for new forms of creativity and sociability (Giaccardi, 2005).

Similar to open design projects, metadesign does not require a final and tangible product or service as an outcome. Thus, metadesign is able to develop a free space for creativity and reflection. Moreover, in those meta spaces, designers can move away from the simple goal of developing a product or a service and be more critical about their activity and their creations.

**Final Considerations**

To consider all the entities that are part of the ecosystem in which design acts is to transcend the idea of a simple artifact as an outcome of the design process. Thus, it is to think about all the
possible interactions and the effects that every design action can have in the ecosystem, which can be exponentiated as a consequence of its complex networked organization. As Giaccardi (2005) claims, metadesign can be an emanating culture, in which the challenges of complexity are addressed through new forms of interaction, creativity, and sociability.

The new forms of interaction associated with open design will allow consumers to become participative and engaged users, changing their relationship with the artifacts that they consume. The challenge of “new designers,” as metadesigners, is how to create sustainable long term relationship with users, supporting their active role (Fischer & Scharff, 2000).

This short paper is a theoretical reflection about the possible benefits of moving toward a meta dimension in design practice. Future studies should consider the effectiveness of this approach in order to reduce product waste, user engagement in open projects, and changing the value proposition of innovation. In order for these changes in the design process to be effective, it is important to study all the possible interactions between humans and nonhumans that can arise in the ecosystem.

Priscilla Boff Ferronato

PhD student in Informatics at University of Illinois at Urbana Champaign, researching the intersection between design, technology and society. She is a researcher assistant and teaching assistant at the School of Art and Design. Her research interests are related to the development of new models of interpretation in open and collaborative design process regarding the solution of social problems. Priscilla did her MDes in Strategic Design at University of Vale do Rio dos Sinos, on the subject of slow and fast thinking, emphasizing the use of intuition in the design process.

Stan Ruecker

Stan is the Anthony J. Petullo Professor in Graphic Design. He came from the Institute of Design in Chicago, where he managed the design PhD and Visiting Scholars program. He was originally tenured in Canada, at the University of Alberta, where he was in the Humanities Computing MA program and the Department of English and Film Studies.

He has undergrad degrees in English and Computer Science, Masters degrees in English and Visual Communication Design, and a PhD in English, Visual Communication Design, and Humanities Computing.

Stan has worked for the past 20 years on the future of reading. He is now looking at the role of prototypes in research, not only in addressing research questions, but also in developing them. Watch for a new book on prototyping across the disciplines in 2018.

Stan is part of an international group developing new predictive models of key concepts for use by designers. Their current topic is how design can help encourage people to expand from holding opinions to making interpretations.

Finally, his team is exploring physical interfaces for complex conceptual work, such as text analysis, modeling time, and designing experience.

He has co-authored with over 230 different people across 21 disciplines and 16 countries.
Driving Home Design Research: A collaborative design case study for developing positive parking experiences on a university campus

Adam Fromme, The Ohio State University, Columbus, OH, USA, fromme.3@osu.edu
Peter Chan, PhD, The Ohio State University, Columbus, OH, USA, chan.179@osu.edu

Abstract

CampusParc, the entity that manages and operates The Ohio State University’s parking assets under a long-term lease, engaged students and faculty in the university’s Department of Design to determine how its brand, services, and parking environments can contribute to a more positive parking experience in garages and surface lots—particularly for visitors to the main campus. This year-long collaboration involved multiple design-definition sessions between design faculty and a CampusParc design strategy team, an 8-week graduate/undergraduate design-led summer workshop, and a full-semester Advanced Visual Communication Design Studio course. The outcomes included discovery themes, user journey maps, observation findings, problem statements, design opportunity proposals, and concept prototypes. Throughout this process, the students worked with, presented to, and received feedback from design faculty and CampusParc representatives. Students engaged stakeholders, university staff, and transient (visiting) parkers. By immersing students into a complex practice-based project, the students applied their design research and service design thinking in environmental graphics and branding. CampusParc is realizing new design opportunities, embracing proposed design themes and concepts, and shifting their role from a ‘utility’ to a ‘service’ provider. This new mindset is contributing to CampusParc’s interest in enhancing relationship building and crafting a friendly and approachable brand language that interjects a sense of delight. This paper captures this collaboration and presents the student-led design solutions as a case study that can serve as a model for future professional-academic collaborations.

Keywords: design strategy, service design, methods and tools, transportation, urban/social

As Ohio's best and one of the nation's top-20 public universities (U.S. News & World Report 2017), The Ohio State University is one of the largest universities in the United States. The university’s main campus in Columbus, Ohio (USA) encompasses 1,765 acres (7 km²) alone, and 16,132 acres (65 km²) in total (osu.edu). The parking system, also one of the largest of its kind, is comprised of 5 million square feet and 13,000 spaces within 16 garages, and 7 million square feet and 23,000+ spaces within 196 surface lots, for a total of 36,000+ system spaces (campusparc.com). CampusParc operates this parking system through a 50-year lease, known as a parking concession, which began in September 2012. CampusParc is responsible for the
Paid parking on the university’s campus has historically not been a popular reality. As a result, CampusParc inherited a pre-existing negative parking reputation from the university. While this is common to most regulatory entities, CampusParc has the additional burden that many of the parking users’s dissatisfaction regarded parking policies, for which the university retained responsibility (including pricing, allocation, and use). CampusParc is attempting to take on that reality by providing the highest quality experience within the confines of their parking concession and the realities of business decisions. Ongoing customer feedback, through the Customer Service Center, annual customer satisfaction surveys, etc. have provided useful insights into customer expectations, perceptions, and opinions of parking.

This project with the Department of Design is to contribute to those insights with viable thoughtful recommendations for improvement. By engaging students and faculty in The Ohio State University’s Department of Design, CampusParc aimed to determine how its brand, services, and parking environments could contribute to a more positive parking experience in garages and surface lots–particularly for visitors to the main campus.

The Department of Design at Ohio State has three undergraduate programs: Visual Communication (“VC”), Industrial, and Interior design; and two graduate programs: Design Research and Development (“DRD”) and Digital Animation and Interactive Media (“DAIM”). The department is committed to regular inter- and intra-departmental, as well as, interdisciplinary collaboration. As so, when the department was initially approached by CampusParc, it was familiar with these types of collaborative engagements.

The Department of Design laid out a plan that would create a learning experience for graduate and undergraduate students within the department, as well as provide valuable insights to the CampusParc organization. Specific activities would be determined as the overall project developed. In an effort to be responsive to the research, many of these activities could neither be established beforehand nor defined with clear outcomes. CampusParc was a willing partner in this design-led, open-ended, and process-driven journey.

To kick-off the project, a year-long collaboration was planned. It would involve multiple design-definition sessions between design faculty and CampusParc representatives, an 8-week graduate/undergraduate design-led summer workshop, and a full-semester Advanced Visual Communication Design Studio course. The project goal was to contribute to an overall parking experience with the university, contribute to the parkers’s comfort level in approaching and finding parking and reaching their destination, enhance the effectiveness of all communication associated with parking and arrival at destinations (within the scope of
CampusParc responsibilities), and improve customer ‘behaviors’ (i.e. reduce littering, destructive activity, etc.).
Summer Workshop (May–June 2016)

The first project began in the summer of 2016. The design faculty, DRD graduate students, and a VC undergraduate student formed the design team. At the kick-off meeting with the CampusParc Corporate Communications Director, the design team received an introduction to the organization, the problem, and the goals of the partnership. During this discussion, it was decided the focus of the Summer Workshop would be to study prospective students and their families, since new student orientations take place during May and June. Additionally, a timeline was determined: Week 1) introduce project and define scope; Week 2) conduct research; Weeks 3 & 4) identify stakeholders; Weeks 5 & 6) map user-Journey; Week 7) frame situations; Week 8) share insights.

This plan was set around two key activities the design team decided would yield the best insights: Stakeholder and User-Journey Mapping. A stakeholder map is a visual representation of the key stakeholder (a person, group, or organization involved with a particular product or service) and their relationship (Curedale, 2013; Stickdorn & Schneider, 2012). This is essential to design teams, allowing them to identify user needs and explore areas of potential design offers (i.e. product/service features and benefits). A User Journey Map is a flow map that tracks users’s steps through an entire experience of a targeted segment (Polaine, Løvilie, Reason, 2013; Saco & Goncalves, 2009; Stickdorn & Schneider, 2012). It visualizes the user’s interactions with the product and service through the context of engagement (Kumar, 2013). This process provides a design team with narratives describing the activities that the targeted user experienced while using the product and service. It facilitates the concept exploration process and inspire useful, useable, and delightful design solutions. These activities were supplemented throughout the project with web-based research, observations, onsite user interviews, and meetings with representatives of the university directly involved with correspondences related to orientation activities.

The design team held weekly meetings to share insights, give informal presentations, discuss and white-board ideas, and set upcoming tasks. Throughout the process the design team documented their work by updating a shared digital workspace and photo-documentation. It was decided to frame found problems and opportunities using an end-user timeline. The decided phases were taken from the User-Journey Map: 1) pre-planning, 2) arrival to campus, 3) parking, 4) leaving the garage on foot, 5) returning to the garage on foot, and 6) payment. Additionally, 7) global and 8) public relation categories were added.

A total of 23 opportunities were discovered. These opportunities included “empower with digital technology,” “simplify garage names,” and “car fob finding” (e.g. Figure 1). They were presented as both an informal exhibit and a final presentation. The 23 exhibit poster were displayed in the presentation space. They each framed a specific opportunity: problem statements, current conditions, proposed conditions, included images, and a short discussion.
The presentation documented both the 8-week process and the findings from the workshop. Both the exhibit and presentation were shown together to CampusParc during the project’s final week.

The Summer Workshop served the design team in understanding many of the conditions surrounding the university’s parking experience first-hand and what changes CampusParc could control. It also provided CampusParc an ‘outsiders’ view of their organization, key insights from a design-oriented perspective, and familiarity with this type of open-ended research process and service design thinking approach. It was deemed a success by both parties and the artifacts from it would go on to introduce future team members to CampusParc and inform future projects.

**Design Studio course (August–December 2017)**

The next project phase moved the design team’s work into the classroom. The design faculty adapted the Advanced Visual Communication course to provide the opportunity for senior
visual communication students to be a part of this sponsored research project. The general course’s description is the application of planning, analyzing, and designing in two/three-dimensional visual communications and information design systems; with an emphasis on application of design research, analysis techniques, design strategic thinking, concept development, implementation, and design evaluation. The CampusParc project was a natural fit within this course goal. A graduate student from the Summer Workshop served as a semester-long contributor to the course, providing an additional layer of carry-over between projects.

The semester was divided into four phases: 1) Discover, 3 weeks; 2) Define, 2 weeks; 3) Explore, 4 weeks; and 4) Frame solutions, 7 weeks. These phases emphasize the processes of a user-centered and iterative design approach that first starts with rational and analytical research of current trends, systems, technologies, stakeholders, and environments; second, strategic interpretations and definition of design intent and context-driven principles; third, generating concepts of clear value and innovative approach; and finally, a consistent, flexible, and appropriate design applications. The conclusion of each phase would be marked with presentations to communicate phase findings and design advancements.

The class was divided into 6 collaborative teams with three students per team. Each team would work together throughout the course schedule. Students were required to apply various design methodologies to discover and identify design problems, opportunities and strategies during the first five weeks of the course. The remainder of the course, each student explored and developed design concepts with proposed solution prototypes in narrative and dynamic video walk-through format. At the end of each project phase, each team and individual summarized the outcomes and process with an oral and visual presentation documentation (printed and digital reports).

After the initial weeks of orientation, research, and learning, each team presented their problem direction in their Discovery Phase presentation. The CampusParc Corporate Communications Director and members from the management and strategy team attended these presentations, providing feedback and offering specific insights. The teams settled on six unique directions: Team 1) “A CampusParc brand campaign” to improve the user’s experience by offering peace of mind through clarity of communication, brand campaign, and delight of the experience; Team 2) “Brand identity update and refresh” to create a more approachable brand perception by humanizing CampusParc and enabling their users to see them as a friendly and helpful organization; Team 3) “Evaluative and generative design toolkit” to reposition CampusParc as a business that focuses on design thinking and service design; Team 4) “ParcPerc, an intuitive parking system and delightful customer appreciation program” to simplify the parking service communication and enhance customer satisfaction by providing added value and positive perception to the CampusParc brand and creating an intuitive parking system and delightful customer appreciation program for student permit holders (e.g. Figure 2); Team 5) “Social care to provide responsive customer service” to change the culture of parking on campus by using social media to connect Campus Parc to the people that use their services; and Team 6) “Memorable navigation through elements of...
nature” to target users’s emotional journey from the garage to the university’s James Cancer Hospital and Solve Research Institute (“The James”). Each team was given the autonomy at this point to proceed as needed to further their specific project goals. Activities included scheduling meetings with university staff, site audits, photo- documentation sessions, direct engagement with specific user groups, and on-site observations.

Figure 2: Team 4 research findings (Opportunity Land and Student Journey Junction)

The design faculty used class time to meet with individual teams, providing direction and instruction. Since project topics were divergent, students worked within their team both in- and outside of class, only re-grouping during progress presentations. This provided student control in project needs and offered a set of “fresh eyes” to other student team projects during presentations. The presentations marked phase transitions, providing checkpoints for progress.

Several of the teams found challenge transitioning between phases, particularly between Phases 3 and 4. While Phase 4 allowed for the production of the required video, documentation book, and presentation, many expressed a desire to continue work on their solution during the final weeks. A few teams were caught with the additional burden of producing final deliverables while a team member continued to generate new materials. Upon later reflection, those students stated that this was a valuable learning experience, both for future professional work and in understanding the demands of team design challenges.
Team 1: CampusPac brand campaign
- Engage university units interested in installing temporary Welcome Signage/Rewards for special events, such as Buckeye Visit Day?

Team 2: Brand identity update and refresh
- Friendlier language in our communications
- More intuitive PAC machines (coming this summer?)

Team 3: Evaluative and generative design toolkit
- More of a service approach to our business
- Perhaps pilot PACPoints to a new customer market, such as sophomores living on-campus?

Team 4: PacPac: intuitive parking system & delightful customer appreciation program
- Tutorial, other video content for web, social media
- Enhanced social media presence
- Seek university partners to re-tweet/repost our messages

Team 5: Using social cues to provide responsive customer service
- Explore affordable, impactful ways to enhance the Campus garages (concrete poles, walls)
- The pedestrian walkways have great potential, but may be cos prohibitive. Worth exploring.

Team 6: Memorable navigation through elements of nature

Figure 3: Final Design Presentation Overview
For the final presentations, teams presented their process and design solution as a digital presentation (e.g. Figure 3). Each was accompanied by a 3 to 5-minute video that used a narrative to realized their proposed solution. In attendance for the final presentation were members from the Department of Design, CampusParc representatives, and representatives of the The James Patient Experience team (who students worked with during their project). Documentation books were also submitted at this meeting.

This Visual Communication Design Studio exploration ended with six targeted directions for CampusParc. Some projects, like Team 2 “Brand identity update and refresh” and Team 5 “Social care to provide responsive customer service” offered insights that could be immediately adoptable. Team 5 went so far as to hand over to CampusParc a “How to” booklet the day of the final presentation. Other projects, like Team 3 “Evaluative and generative design toolkit” and Team 6 “Memorable navigation through elements of nature” offered CampusParc a very ‘blue sky’ perspective. One thing was clear, each team offered CampusParc new design opportunities from the user-centered and service design perspectives. CampusParc left the final presentations expressing an eager excitement to meet with the design team and discuss future steps.

The CampusParc representatives responded with valuable feedback for each team from business management and strategic perspectives. Team 1 “A CampusParc brand campaign” Their recommendation reinforces the need for CampusParc to balance regulatory requirements of a parking facility with parkers need for a friendly and approachable experience. Team 2 “Brand identity update and refresh” CampusParc would be able to implement/install/apply the recommendations within constraints of budget and university policies. Realistic costs and production requirements. Proposed design prototypes are effective and relevant. Team 3 “Evaluative and generative design toolkit” Their recommendations align well with CampusParc’s business and strategic interests: possible revenue generation; contributing to a positive parking experience among key customers; enhancing the parking environment. Clear and creative visual approaches that emotionally-connect to stakeholders. Team 4 “ParcPerc, an intuitive parking system and delightful customer appreciation program” Both the university and CampusParc find the ideas appealing and of interest and benefit to key audiences. There is great potential that both CampusParc and the university would find some “news value” and benefit from the implementation of the recommendations. Team 5 “Social care to provide responsive customer service” this project provides a holistic design approach based on insightful discovery, in-depth concept exploration, and forward-thinking solutions. Team 6 “Memorable navigation through elements of nature” this project provides researched and innovative ideas that align with mission of The James and could be implemented in future garage designs and parking service for the functional and emotional needs of the hospital patients, visitors, and staff.
Outcomes

The two sponsored design research and concept exploration projects in this year-long collaboration satisfied the initial project goals to determine how CampusParc can contribute to a more positive parking experience in garages and surface lots around the campus environment. Additionally, while CampusParc knew the Department of Design had something to offer (based in part on positive past experience the Corporate Communications Director had working with the department), this was a design thinking experience with Design Research and Service Design. It was their willingness to be open to allowing the students and faculty determine each project direction that allowed the department to offer new ideas that inspire useful, useable, and delightful design solutions.

To round out the year-long project members of CampusParc and the design team met in the Spring of 2017 to discuss the outcome of these two projects and to discuss research and design approach for the next academic year. The outcomes included discovery themes, user journey maps, observation findings, problem statements, design opportunity proposals, and concept prototypes. The team identified four future project directions: 1) “Brand and Personality” to perform a comprehensive brand audit; 2) “Social Care” to build assets and infrastructure for social media efforts; 3) “Friendlier CampusParc” to potentially pilot campaigns at the Union Garage related to visitor events; and 4) “The future new garage for The James” to form a design/technology partnership to explore virtual reality (“VR”) prototyping for future construction.

The design faculty furthered its model for collaborative research, developing meaningful coursework, and providing ‘real world’ problems in the classroom. Students were able to work with, present to, and receive feedback from design faculty and the CampusParc team. Additionally, students engaged stakeholders, university staff, and transient (visitor) parkers. By immersing students into a complex practice-based project, the students applied their design research and visual communication coursework, used service design tools, and applied design thinking methodology in environmental graphics and branding.

Future work

CampusParc is now realizing new design opportunities, embracing proposed design themes and concepts, and shifting their role from a ‘utility’ to a ‘service’ provider. This new mindset is motivating CampusParc’s focus on the entire customer journey (rather than just the parking transaction), crafting a friendly and approachable brand language that interjects a sense of delight while supporting confidence and loyalty. They are also committed to finding opportunities to collaborate with university experts to inform their decision making.

At the start of Autumn 2017 the team decided to advance “The future new garage for The James” project and formed a design/technology partnership to explore VR prototyping. A 9-month collaboration is now underway for “Human-centered and desirable parking experience”.
This is a collaboration currently has 23 team members from parking system management, patient experience experts, OSU faculty and students, design practitioners, and technology application developers identifying core design values to create a holistic user journey by exploring physical and emotional experiences related to the future parking experience at The Ohio State University.

Adam Fromme is a current MFA Candidate in the Department of Design at The Ohio State University, where he also earned a BSD in visual communication design (2006). His current research activities focus on collaborative design, successful aging, transportation, and public space. He has previously lectured in Visual Communication Design at The Ohio State University. His professional practice areas include wayfinding and environmental graphic design, hospitality and health care design, and identify and visual systems. He also founded the design consultancy firm Wayfind Design LLC in 2014.

Peter Chan, PhD
Peter Kwok Chan is an Associate Professor of Visual Communication Design at The Department of Design, The Ohio State University. He received his BFA from Minneapolis College of Art and Design (1986) and MFA from Rhode Island School of Design (1988) in graphic design. He obtained his Ph.D. from The Ohio State University (2003) in Art Education. He formerly practiced brand identity design and management, created visual communication design systems and packaging design, and conducted design research at Fitch (Columbus, Ohio: US headquarters) and The Procter & Gamble Company (Health Care Research Center, Mason, Ohio). His research focuses on Brand Design, and concerns the methods, techniques, and approaches that design students learn to explore, interpret, and apply emotion-driven design to strategic design problems. He has served as design advisor for many nonprofit, for-profit and academic groups. Peter’s creative works have won recognition from American Institute of Graphic Arts, Columbus Society of Communicating Arts (CSCA), Communication Arts, CA Interactive, HOW, IDEA, IDSA, Print, and Typography.
Building capacities to author change: community-based participatory design as a form of positive youth development and adolescent sexual and reproductive health care intervention design

Abstract

The term “community-based participatory design” (CBPD) recently emerged as a distinctive space in the Participatory Design tradition (DiSalvo, Clement & Pipek, 2013; LeDantec, 2016). This move marks a shift from treating the process of design primarily as a product development method, to one that builds social and technical capacities – or infrastructures – of individuals and communities (Björgvinsson, Ehn, & Hillgren 2010; Karasti 2014; LeDantec 2016). This paper describes participant gains from a design workshop conducted as part of a research collaboration involving a university-based research center, and four NGOs, the participatory design workshop aimed to: (1) build the capacities of young people; (2) guide young people in the creation of novel and locally relevant gender and sexual and reproductive health (SRH) solutions; and, (3) bring voices of young people into research and programmatic questions around gender and SRH in the public health domain. The workshop was conducted with 31 young people aged 15-25, over 2.5 weeks, in Lucknow, Uttar Pradesh, India. The evaluation demonstrates that the workshop resulted in exposure to working in mixed-gender teams, developing problem-solving skills, and increasing SRH awareness and knowledge. The workshop produced six low-fidelity prototypes, five of which were subsequently refined and piloted by three Lucknow NGOs.

Keywords: community-based participatory design, adolescent sexual and reproductive health, user gains, evaluation, infrastructuring

Participatory design (PD) processes have been adapted and reinterpreted for a variety of design contexts and purposes, resulting in a broad range of philosophies in PD. Most recently, “community-based participatory design” (CBPD) has emerged as a small subfield of PD research and practice that aims to foreground social constructs and group relationships in settings that may include, but also reach beyond, the organizational structures foregrounded in typical workplace studies (DiSalvo, Clement & Pipek, 2013). This move also marks a shift from treating the design process primarily as a product development method, to one that builds social and technical capacities – or infrastructures – of individuals and communities (Björgvinsson, Ehn, & Hillgren 2010; Karasti 2014; LeDantec 2016).

The concept of “infrastructuring” has surfaced in PD literature to describe the creation of socio-material assemblies that support sustainability of design outcomes (Björgvinsson, Ehn, & Hilgren, 2012). Star and Ruhleder (1995) were the first to describe how infrastructures emerge in relation
to organized practices. Björgvisson, et al., (2012), have described the socio-material assemblies that emerge from infrastructuring in design processes as “design Things,” suggesting that ‘Things’ are not merely the byproducts of the design processes but the objects of design in and of themselves. This framing naturally calls for a better understanding of the evolution of relationships, networks and resource flows that drive Things forward.

Participation is central to Things. Understanding what participants gain from participation then represents another way for us to understand and evaluate the distributed and diffuse impacts from CBPD. However, not until very recently has the evaluation of “user gains” become of interest to the design domain (Bossen, Dindler, & Iversen, 2010, 2012, 2016). Balka (2010) notes, that despite the ideals the PD community holds close, rarely do we research what participants in design processes gain from their participation, or their views of PD processes and outcomes. According to Bossen et al. (2016), there have been few explicit, systematic process evaluations in PD. Muller (2002) has noted that the dearth of formal evaluation represents a weakness in the literature on participatory practices.

This study seeks to better understand what participants gain from their participation in a design workshop, in order to contribute to discussions in the PD literature about user gains relative to CBPD processes and Things. This study describes how a research collaboration involving a university-based research center, and four NGOs, used a participatory design workshop with the aim to: (1) build the capacities of young people; (2) guide young people in the creation of novel and locally relevant gender and sexual and reproductive health (SRH) solutions; and, (3) bring voices of young people into research and programmatic questions around gender and SRH in the public health domain.

**Kissa Kahani Participatory Design Workshop**

**Background**

The Center for Interdisciplinary Inquiry and Innovation in Sexual and Reproductive Health (Ci3) at the University of Chicago is executing Kissa Kahani, a study that uses participatory research methods, and qualitative and quantitative methods, to understand gender, and sexual and reproductive health (SRH), among young people living in Lucknow, Uttar Pradesh (UP), India. As India’s most populous state with a large percentage of young people ages 15-24, UP has among the highest levels of gender inequality in India. The state ranks 34 out of 35 on the gender development index, which measures differences between men and women in health, education, and economic capital (UNDP). These disparities create intersecting, systemic challenges to the health and wellbeing of women and girls. Nearly 21% of girls in UP get married before the age of 18 (DLHS-3). Almost 18% of women age 15-49 have an unmet need for family planning, and only one-third use any modern method of contraception (NFHS-4). Kissa Kahani addressed these and other such indicators in gender and SRH by exploring the lived experiences of young people in UP.

Kissa Kahani has four phases. In phase one, four narrative-based participatory research methods were employed to help youth discuss gender and SRH. Phase one used four narrative participatory methods: (1) life course interviews that explored critical moments in the lives of young people such as their birth, education and marriage, n=123; (2) body mapping workshop
for visual representation and analysis of young people’s experience with gender and SRH, n=40; (3) narrative-based game workshop to co-create stories related to gender and SRH, n=40; and, (4) story circles that formed safe spaces to conceptualize, share and receive feedback on personal stories around gender and SRH, n=74.

In phase two, grassroots organizations in India applied for funding to develop innovative, adolescent-led interventions to address the issues identified through phase one research activities. In phase three, young people participated in a 2.5-week participatory design workshop to create novel and locally relevant gender and SRH solutions. Phase four involved funding local organizations to refine and pilot adolescent-generated solutions.

The participatory design workshop, the focus of this study, had two goals: First, to use a community-based, human-centered, participatory design process as a form of Positive Youth Development (PYD), in which youth were engaged as equal partners. PYD seeks to build or fortify relationships with adults and social networks, to develop the skills necessary to engage in real-world roles and activities, as well as orient youth toward future goals (Catalano, Gavin, & Markham, 2010). As a form of PYD, the workshop aimed to: (a) be a vehicle for young people to think about adolescent health issues from their point of view and the point of view of others in Lucknow; (b) offer an opportunity to explore everyday problems in new ways; and (c) bring meaningful collaborations into being (‘thinging’). The second workshop goal was to guide young people in the creation of novel and locally relevant approaches to mitigate gender disparities and improve adolescent sexual and reproductive health (ASRH).

Workshop structure
Thirty-one participants (22 girls, 9 boys), between the ages of 15-24, were recruited to the workshop by three local NGOs. Participants were organized into six mixed-gender teams, of 5-6 participants according to the NGO that recruited them, meaning that participants in each team were all recruited by the same NGO. Workshop materials, including a bespoke 70-page human-centered design (HCD) primer, and the workshop itself, were delivered in Hindi. Themes for workshop design challenges were developed from the four narrative-based participatory research methods, used in the parent study, Kissa Kahani, designed to help young people discuss gender and SRH in phase one.

Six design challenges were developed around themes that emerged from phase one data: (1) healthy bodies and healthy relationships: providing SRH education to young people; (2) public safety for girls and young women; (3) gender equality in high school completion rates; (4) supporting young men in their SRH needs; (5) rethinking gender roles; and (6) social media.

The Ci3 team trained five coaches, adults recruited through NGO partners, to co-lead the workshop. They received a two-day crash course in HCD, and worked along Ci3 Design Thinking Lab team members to teach five workshop teams the HCD process through activity-based modules. HCD modules included problem framing and reframing; qualitative methods for contextual research (e.g., identifying research questions and sampling strategy, conducting intercept and in-depth interviews, data collection methods); data analysis (e.g., clustering themes, identifying insights and design criteria); concept generation and evaluation; prototyping (e.g., storyboarding user journeys, role plays, low-fidelity “franken” prototyping); and
Figure 1. Excerpt from workshop primer module on qualitative methods for contextual research.

Figure 2. Overview of Kissa Kahani participatory design workshop.
communicating novel ideas to new audiences (i.e. pitching). Modules were immediately followed by in-context application of methods to explore the design challenges selected by each team. For instance, teams interviewed a variety of people including parents, peers, tut-tut drivers, pedestrians, shopkeepers, a local alderman, a Lucknow police director, a UP cricket coach and a gynecologist.

After the workshop, the five concepts prototyped by the participants were further refined and developed by the three partner organizations in Lucknow and Ci3. These concepts, with accompanying evaluation tools, were piloted in Lucknow in the six-months following the workshop and were recently completed.

Evaluation activities
Baseline and endline surveys were conducted before and after the workshop and took, on average, 30 minutes to complete. Due to time and financial constraints, survey questions could not be pre-tested prior to their use in the field. Surveys were conducted in Hindi by UChicago and Lucknow-based, partner-affiliated research staff, using an android-based tablet with REDCap software. The baseline survey was conducted with participants in-person and over the phone. Endline surveys were completed in-person. The survey aimed to measure participant attitudes and capabilities relative to the skills-based activities that constituted the foundation of the workshop by asking questions about their familiarity with human-centered design, about how likely participants felt like they could participate in new activities, like talking with strangers (i.e., interviewing), et cetera. The survey data was analyzed by members of the UChicago research team using the Wilcoxon signed rank tests and Mann Whitney tests in STATA.

Focus group discussions were completed in a closed room with each team. Discussion topics included questions about what participants liked about the workshop, what could have been improved, what they learned through the workshop, and current challenges they face as adolescents. Focus group audio recordings were translated and transcribed by a third party, de-identified, and coded for major themes by the UChicago research team.

Discussion
Analyses of the data suggest that the use of a participatory design workshop as a form of PYD resulted in user gains in three areas: building relationships and networks, skill building, and an increase in ASRH awareness and knowledge.

Building relationships and networks
Focus group data suggests that the workshop provided a unique opportunity to work in mixed-gender groups resulted in greater exposure and comfort in working with the opposite sex and in groups. For instance, one participant described:

_I had individually worked at a lot of places, but this was my first opportunity to work in a group. So, I gained the experience of working in a group, so that was the best thing for me. There were girls with us in the group as well, so that was an entirely different experience. So that was really good for me (FGD 06)._
Skill building
Both focus group and survey data suggested that participants experienced an increase in their likelihood to generate new ideas in response to a social problem, and to speak to someone they had never met before to seek help for solving the problem. One participant noted:

To make an idea and to present that--it was difficult as well as challenging. We did make it and present it. It was quite fun. I am now confident that if I get a chance again, I can make an idea and execute such kind of job at ease (FGD 03).

Focus group data also indicated that the workshop increased self-confidence for interviewing individuals as well as public speaking. For instance, one participant stated: I liked it because we were able to take interviews and this way we developed confidence to work and interview others (FGD 01).

According to survey data, both young men and women reported an increase in attitudes about and capacity for implementing design activities; however, young men reported a stronger change in this compared to girls.

Increase in SRH awareness and knowledge
The workshop raised awareness about issues in ASRH and gender, and generated further interest in learning about them. One young person stated:

Things like we were not aware about body parts and what happens between girls and boys during sex, but we came to know on that day, and we were stunned to see and hear that these sorts of things happen between girls and boys (FGD 05).

These findings suggest that the workshop may have built participant capacity to act beyond the activity of solving for an acute problem, in this instance, creating locally relevant design solutions for gender and ASRH-related challenges.

Limitations
This evaluation was conceptualized as a formative research to identify suitable measures for assessing user gains in the context of CBPD. The authors recognize there are limitations to the study design. First, evaluation tools were not pre-tested with Indian adolescents to assess potential issues of clarity and acceptability of questions. Second, participants had been involved in community-based work with local NGOs prior to the workshop, therefore they may have had more opportunities to acquire and implement skills taught in the workshop when compared to other young people. Lastly, the overall project structure did not allow for a follow-up survey at a later time interval to assess (a) if the change in attitude toward capacities that were reported at endline were retained by participants for a longer duration, and (b) to learn about their subsequent experiences applying skills.

Conclusion
This study makes a contribution to the small, emerging body of CBPD research concerned with the evaluation of user gains. It illuminates specific affordances that Kissa Kahani design workshop processes had relative to facilitating new socio-material infrastructures for young
people engaged in the design of novel gender- and ASRH-related public health interventions. Exposure to teamwork and mixed-gender teams allowed for new forms of social infrastructuring for participants. Building skills that could be used in real-world roles and activities, and increasing SRH awareness and knowledge such that it could inform orientation toward future goals, represent kinds of technical knowledge infrastructuring.

In turn, these infrastructures also connect to the prototypes and pilots conceived in the workshop, and the subsequent evolution of the relationships, networks, and resource flows that may support the sustainability of their implementation in the community. Therefore, at its center, this study represents a case about how social configurations, give rise to, and then evolve in response to, new kinds of Things.

In the context of gender disparities in Uttar Pradesh, the user gains suggested by this small study challenge the usual ways how social and technical infrastructures might normally emerge in the design of public health interventions, allowing for the evolution of locally relevant approaches to mitigate gender disparities and improve ASRH. In this way, the study connects to the ongoing discourse about the role of PD as means to engage with power structures and marginalization.

Author Biographies

Amanda Geppert, MPH, MDM

Amanda is the Director of the Ci3 Design Thinking Lab at the University of Chicago where she develops innovative community- and clinic-based interventions to advance the health and assets of young people around the globe. Amanda holds a MPH in community health sciences from the University of Illinois at Chicago School of Public Health and is currently pursuing a PhD at the IIT Institute of Design. Her doctoral research explores the development and evaluation of community-based participatory design processes that seek to build capacity. Previously, Amanda led national program replication for Cure Violence, an evidence-based public health approach to reduce shootings.

Suchi Bansal, MPH

Suchi is a research associate on Kissa Kahani. She has extensive experience with adolescent sexual and reproductive health issues in developing countries, specifically in South and Southeast Asia. Prior to joining Ci3, Suchi worked with multilateral and public health organizations including The World Bank and Pathfinder International, where she examined issues of teen pregnancy, menstruation management, and family planning. Suchi has a Master’s degree in Public Health from Columbia University and Bachelor’s degree in Economics and International Relations from Knox College.

Melissa Gilliam, MD, MPH

Dr. Gilliam is the Principal Investigator on Kissa Kahani. She is Professor of Obstetrics/Gynecology and Pediatrics, founder and director of Ci3, co-PI of the Game Changer Chicago (GCC) Design Lab and Vice Provost for Academic Leadership, Advancement, and Diversity at the University of Chicago. Dr. Gilliam’s research focuses on understanding and addressing health disparities among youth. Early in her career, Dr. Gilliam recognized that research and intervention efforts needed to broaden from traditional clinical models to effectively address social and structural determinants of health. Thus, Dr. Gilliam founded Ci3 to leverage technological and academic resources against the ecology of factors that lead to health disparities among youth. Under her leadership, Ci3 undertakes innovative projects with youth, including summer digital storytelling workshops and game-based learning experiences.
Shirley Yan

Shirley is the current outgoing program manager for Kissa Kahani, which aims to understand how adolescents think about gender and sexual and reproductive health in Lucknow, Uttar Pradesh, India. As part of her role she manages all parts of project implementation to ensure stakeholders are involved and deliverables are met. Previously, she has worked on projects that center around how communities can be motivated to make healthy behavior changes, specifically through community-based and human-centered design perspectives. Examples of these projects include job creation in the Indian textile sector; assessing benefits of a food prescription program in Chicago; and developing a waiting room app around contraceptive knowledge. She is currently pursuing a Masters in Science in Public Health in Social and Behavioral Interventions at Johns Hopkins Bloomberg School of Public Health and holds a Bachelor’s degree in Public Policy from the University of Chicago.
Humanizing an Organization through Digital Experiences

Abstract

Student life at a large institution like University of California, Berkeley, is challenging in many ways. Along with the often extreme academic demands, students must discover and navigate numerous services while simultaneously integrating themselves into formal and informal campus communities. Historically, core student services were delivered in a piecemeal and disjointed way via a dozen or more websites. A large investment in a Student Information Systems (SIS) replacement project has since unified these service experiences through CalCentral, a Berkeley-developed service portal, and created with a significant focus on user experience design.

While significant strides have been made to improve and simplify how services are delivered to students, the design team has been challenged to push their vision of the service ecosystem further, to “humanize the institution.” The vision goes through the SIS project and beyond, by first switching mindsets from service producers to service providers, and second by looking at how deeper relationships can be created digitally between students and the institution. The research, with students and different stakeholder groups, shows that beyond usability and learnability, there are greater opportunities through service design to contribute to students’ senses of agency, inclusion, connectedness and wellbeing. The design team is codifying new design principles and developing prototype experiences that look more closely at tone, behavior and contributing to a positive emotional state of mind. The service delivery through CalCentral is humanized and augmented in affirming ways, to use language that is accessible, and to guide students through complex paths.

Keywords: service design, humanizing, student services, organization change, transformation design
Introduction

The University of California, Berkeley is the preeminent public research university in the world, founded in 1868, now with a student body of over 37,000 and a world-renowned faculty that includes seven Nobel Laureates. This large organization forms a unique ecosystem of people, functions and systems that in its scale can have a high complexity. To renew the ecosystem, the University embarked on a large and complex project in 2015 to replace a number of existing aging systems that comprised the Student Information Systems (SIS). The project transitioned to an ongoing operation, mid-2017.

The SIS project aim was to enable the transformation of the student experience during their studies by providing a single portal — Berkeley-developed CalCentral — as the primary service delivery vehicle for students, faculty and advisors. Through easy access and use, the portal supports and guides the student in the processes of admissions, enrollment, registration, financial aid, billing and payment, and advising. In order to deliver the desired student experience, the project included research into the work of faculty and staff. The CalCentral portal aims for a switch from service producers in departments offering piecemeal services, to a model of service providers operating across a common platform with simplified and unified self-service tools and information.

Unlike in a traditional information technology (IT) development project, the sponsors and leaders of the SIS project wanted to position the initiative as a business transformation initiative. The positioning of the project offered opportunities to look at the system from a different perspective and to apply user-centric methodologies in the process.

Within the context of a university, the emphasis and investments in creativity, design and service innovation is not self-evident and are usually made in support of the academic experience. In contrast, less emphasis and few resources are charged with addressing opportunities to reduce the administrative burdens and obstacles that detract from learning, research, degree progress, and self-actualization. Here, risk aversion and budget constraints contribute to a service landscape that can be lacking in creativity, where the incentives to improve service offerings are limited, and where the tolerance for change to administrative functions is at the incremental level. The SIS project however, afforded the University a rare opportunity to look broadly and systematically at administrative services, both technically and from a service delivery perspective.

In the SIS project the user experience (UX) design team worked as a gateway between the technology and users (students, faculty and staff) to find out the real needs and pain points in
their processes, to involve the users in the design process and to create designs that answer to the recognized needs. Even though the UX team is relatively small compared to the size and complexity of the entire project, 4 designers plus 5 portal developers in an overall team of 220 people, it played an essential role in making the voices of users heard. The assessment of administrative services through a user-centered design lens made it clear that there are large opportunities to streamline, simplify and reduce operating costs and significantly improve service experiences for all stakeholder groups.

There is also pressure from outside of the university to improve service delivery. The amount of services in businesses and organizations — the so-called “servitization” (e.g. Lay, 2014) — is increasing. This continuous implementation of services has been shown to be an essential part of providing the most effective solutions to users (Vargo and Lusch, 2006). Just like any other customer, students follow their individual service paths through the crucial touchpoints, and make decisions based on their personal needs and context through the service micro moments (Stokes and Harris, 2012). As students have become accustomed to consuming digital services in a convenient and frictionless way based on their own choices, they have also high expectations for digital services during their education.

Coming from the theory of product-service systems (Morelli, 2003; Roy and Baxter, 2009; Wieland et al., 2012), the paper looks at the SIS project as a digital service ecosystem that provides digital service experience, and introduces an on-going research effort with a focus on how the overall educational experience can benefit from examining administrative service touchpoints, and where opportunities exist across critical journeys to increase understanding and support decision making.

The research is done as practice-based research (e.g. Candy, 2006) through several individual use cases connected to the student’s educational journey. A research goal is a holistic understanding of the opportunities for design and development. The paper explains the process of the current research and introduces the initial results of the research analysis that give the framing for the future research and design activities.

The SIS project recently transitioned into operations. While significant progress was made to reimagine administrative service in a unified way for students and faculty, the paper looks at how humanizing principles can be codified and championed in ongoing user experience design work on campus.
Literature Review

A common practice with technology projects on campus is to focus on delivering the required functionality by gathering requirements from the service provider side and working inside-out to configure and set up the necessary service delivery model. With the SIS project, an outside-in approach was incorporated by the UX designers utilizing the service design methodology with the goal of developing easy to learn and use tools for key end-users.

Service design is a discipline that combines a human-centered approach into a design of deeply considered service systems with concrete and intangible attributes (Stickdorn and Schneider, 2012; Løvlie et al., 2013). For the UX team, service design tools were a way to co-create with users (e.g. Kukk et al., 2014), to include the key stakeholders into the design process, to collect user needs and to understand the customer experience (Mayer and Schwager, 2007). The service design approach helps to form design challenges, ideate, conceptualize and prototype service experiences (Buchenau and Suri, 2000; Miettinen, 2011), design detailed services with holistic user journeys (e.g. Nenonen et al., 2008), and to implement, improve and scale the service solutions (Løvlie et al., 2013; Geuy, 2016).

During the course of the project, the UX team was challenged to expand their original vision of service and to look for ways to “humanize the institution.” Finding the right form of creating the service solutions was guided by a human-centered approach (Cook et al., 2002; Frazer Windsted, 1997) in the organization. The human-centeredness starts from understanding the customer but is realized through the service touchpoints (e.g. Clatworthy, 2011) by noticing the user as an individual and giving them a personal experience.

To “humanize” the digital service experience, the human-centered mindset is needed in the organization (Rytilahiti et al., 2016), which appears in practice also as the adoption of design methods both at the operational level to design the service solutions and at the strategic level for the change of the organization (Sangiorgi, 2011). Focusing first on the operational needs, the UX team saw an opportunity to deepen a student's emotional relationship with the University, and for the student to feel that the institution “has their back” through their academic journey. What this looks like and how to codify it into design principles and designs would be part of the team’s research effort. In addition to expanding and pushing on the team’s design principles, it was clear that the team had a need and opportunity to more clearly articulate and socialize the value and impact of design on campus, as a force for ongoing and transformative change.
Research Methods

The research data has been collected through practice in several use cases following three key student journeys (Table 1). Journey mapping has been a key strategy for the SIS project and the UX team to anchor and design for both macro and micro views of end-users’ experiences. The initial aim of the practice-based research has been to identify what students’ needs are in terms of the provided service elements in the CalCentral portal, and to explore what “humanizing” means and looks like from a design perspective for digital experiences. For this purpose the UX team has conducted a number of research activities including student interviews (Portigal, 2013) and co-creation workshops (Sanders and Stappers, 2008) with students.

Table 1: Description of the use cases included in the research

<table>
<thead>

<th>Student Journey</th>
<th>Hypothesis</th>
<th>Research Methods</th>
<th>Key findings for design needs</th>
</tr>
</thead>
</table>
| Undergraduate onboarding         | Students are overly stressed and confused about the number of tasks and decisions that they must make, from application till their first day on campus as a student. There are opportunities to guide the experience through critical gates. | Student interviews (N=15)  
Experience mapping workshop (20 staff members)                                                                 | Status messages are unnecessarily alarming.  
Required actions are sometimes missed.  
Deeper opportunities exist within service areas, e.g.: housing. |
| Funding and paying for my education | Financial Aid and Billing departments' business functions don’t map to students' mental models and limited knowledge of how to finance their education. | Design Workshop for Students (35 students)                                                            | Language usage and knowledge barriers  
Workflow is poorly signaled through the user interface resulting in questions like: how does this work, what is my status, what happens next and when?  
A lack of tools to support decision making |
| Academic planning and enrollment | The rules, tools and processes around planning for and enrolling in classes are opaque, confusing, and hard to navigate to achieve the desired results. | Student-built strategy map (6 students)  
Student interviews and survey input (N=85)                                                                 | Functional restrictions and a lack of transparency are reducing self-service agency resulting in increased traffic to advisors and academic staff |
Co-creation Workshops

For onboarding, interviews were collected from 15 students as input for a workshop. Each service provider participant was responsible for conducting an interview and sharing the results in an experience mapping exercise that located a number of service improvement areas.

Interviews were also coded to quantify happy, neutral and unhappy sentiments by service to create an opportunity “hot spot” map that highlighted areas for deeper research and investment.

To understand students’ financial service needs — in particular how students understand and interact with financial aid offers and billing — approximately 35 students participated in a design studio workshop where they brainstormed pain points and then used whiteboards to design new digital experiences. The UX team videotaped the student teams as they presented their designs to capture the comments and ideas, and for more detailed textual analysis.

For academic planning and enrollment, SIS project student employees were charged with deconstructing and mapping their processes in a whiteboarding workshop. The journey map looks beyond basic tools and functions, and identifies key decision points including a prioritized set of information sources (Figure 1). Additional input came from students in a “town hall” style meeting and through a survey.
Discussion

The opportunities for service improvements are many. The analysis shows that students are facing many challenges as they navigate campus life. While CalCentral has created a unified service delivery platform with a focus on organizing, alerting and presenting data to end-users in a user-centric way, the UX team has identified some key findings that will inform future research and design activities, including:

- Augmenting alerts and messages for context setting.
- Designing workflows that guide journeys and decision making.
• Improving transparency with university processes to increase understanding.
• Using accessible language and a guiding tone.

These key categories of research and design opportunity areas were defined to help the framing of the future research: information and knowledge; communication; transparency; workflow guidance.

Another key finding is the close connection of digital and in-person services. Even though the services would be provided through different backend systems, in the overall experience all the steps in the process can be assumed to belong together. In order to be successful in a service delivery, and truly humanize the institution, the digital experiences must align with in-person experiences.

Humanizing the Organization

When discussing the topic of “humanizing the organization” with students, they immediately drew upon their interactions with people on campus. The research has shown that in the context of digital services, the cognitive load of students (Mullainathan and Shafir, 2013) and the emotional relationship with the institution can be greatly improved through an investment in service design and through the goal of humanizing the institution. Humanizing the organization can mean taking the time to understand the profound needs of the user, basing the design on user needs (Pinheiro, 2014), involving the student, faculty and staff in the design process through co-creation, and providing human-scaled solutions characterized by reduced complexity and context-appropriate language and communication.

The themes that have emerged from the initial research analysis point towards humanizing the organization. Our focus on the key challenge areas of delivering digital services revealed an opportunity to augment the ability of the students to act (Manhaes, 2015) in their best interests and to be successful in their pursuits of their academic goals. The ability to act comes from having the needed knowledge and support, which can be also an empowering experience (Gantier and Labour, 2015) for the students in their educational journey.

Augmenting the ability to act must be done in a guided manner, with a deep understanding of students and their needs, and through workflows and language that is aimed at students, not administrators. Also the underlying policies and business practices must be transparent to enable students to understand the rules of the system and process, and to navigate and pursue a winning strategy for themselves with minimal uncertainty. Addressing these findings will
contribute to students’ senses of agency, inclusion, connectedness and wellbeing, which in turn will make the institution be perceived as more human.

An output of the analysis is a maturity model (Figure 2) that describes the different stages of humanizing the organization through design. This model addresses an overarching desire to “augment the potential to act” (Manhaes, 2015), and imparting knowledge, through design solutions, that inform and empower decision making. This model is predicated on a design-driven set of methodologies where the context, needs and emotions of users and stakeholders are well understood, and the service focus and pathways of end-users have been mapped out. The model illustrates the starting state of traditional Information Technology (IT) methods, UX design focus for the service system, and the focus on greater personalized experience through Service Design. These three steps are familiar activity for the SIS project UX team, but in order to achieve the humanized organization, organizational transformation is required.

As a discipline, transformation design includes the aspiration of tackling problems that are complex and ambiguous. Through collaboration between different disciplines and by employing participatory design methods, transformation design aims for creating fundamental change.

Building the needed capacities and using the design skills, transformation design provides the first steps towards a changing culture and organization. (Burns et al., 2006)
The transformation of a culture or organization is an ambitious approach that requires noteworthy time and effort as it aims to transition the organization from the current state to the visioned state (Manhaes, 2017). It also necessitates close collaboration between partners and stakeholders. As Pirinen (2016) explained “collaboration is a transformative capability that necessitates the crossing of the structural, cultural and other boundaries of individuals, organisations and networks and can be supported by strategic, operational and cultural integration, by the creation of trust and through the recognition of mutual value among the actors.” With the human-centric skills, designers have the opportunity to support the transformational change from the operational level and to strategic level (Sangiorgi, 2011).

Conclusion

Future Research

The overarching goal of the UX team will be to design in a way that best supports students’ knowledge and sense of empowerment, in context and in support of key service touchpoints. It will be important to benchmark and track metrics that indicate students’ senses of agency, and understanding.

Tactics will include:

- Codifying guidelines around language use and tone
- Designing micro moments that celebrate progress and affirm actions
- Codifying and demystifying complex workflows, and exposing rules and options
- Guiding decision support and strategic choices

In the case studies shared, business cases can be developed to quantify and qualify savings in staff time by improving the self-service functionality for students through the portal as well as addressing staff transactional workflows. Now that the SIS project is in operations mode, and there are fewer resources available to develop improvements, the relative value and impact of addressing these use cases must be weighed to determine where the greatest return in staff time can be achieved. Value assessments are becoming a critical activity in a resource constrained environment. Here, the UX team continues to provide vital input to the question of return on investment, or as they prefer, Return on Experience (ROE).

Against this backdrop, the UX team must continue to advocate for the value of design through use case design and research. Creating a vision for humanizing through design allows the UX team to contrast where they have come from with a future state of services.
experiences on campus. The UX team is early in its implementation of humanizing design principles, which it sees as going hand-in-hand from a cost/benefit perspective with improving the digital experiences of students, staff and faculty. Figure 3 shows the proposed model for how the UX team must interact with business and technology colleagues.
The UX team also values and benefits from sharing design use cases and ideas with members of the design community, in the public and private sector, as well as within academia. For example, a rich source of insights for this paper came from an in-person conversation with Mauricio Manhaes (Professor of Service Design at SCAD) at the Service Design Network US conference in Chicago, June 2017, and through his writings. Manhaes equated “humanizing” with a more tangible and action-oriented framework of “augmenting the potential to act.” “Before we can act, we must have the knowledge,” Manhaes said. As a preeminent university, whose core mission is research and teaching, looking for design opportunities that impart knowledge and empower students is a meaningful cause and pathway for the UX team at UC Berkeley to contribute to institutional goals.

Lastly, to achieve the transformative state from the maturity model (Figure 2), the UX team believes that staff with strong design disciplines must exist both inside and outside of the IT organization working with leadership, to facilitate problem finding and problem solving at a strategic institutional level.

Abstract:

The environment in which patients (need to) reside has a great influence on their wellbeing (Ulrich, 1991). That is why introducing ‘Design for Wellbeing’ is key in the design of palliative environments. People in the last phase of their life become more receptive to environmental stimuli. From our perspective, this triggers design to become even more relevant in such contexts. People’s search for subjective well-being (SWB) has promoted a change in vision in the design of new products, services and environments, with a focus not only on material properties, but also on the personal values that trigger actions that can contribute to people’s SWB. Such considerations contribute also to proposing answers to the question of how design can support people to have a meaningful life and ‘be well’ in the best possible way, according to the circumstances.

The purpose of this paper is firstly, if design for wellbeing can be performed in the context of palliative care, and secondly, how research could be set up in such a precious context. A thorough literature review will be performed to answer these questions. The value of this study lies in aiming to try to enable terminally ill patients and people from their immediate surroundings to cope with these events via design, and to stimulate people to be able to perform activities that they like (most) and which contribute to their SWB.

*Keywords: design for wellbeing, palliative care, interior architecture, last phase of life.*

Nowadays, palliative care promotes advanced care planning and aggressive symptom control in patients with severe illness (Dans & Sheldahl, 2015). In its beginnings, palliative care centers were established for terminal patients diagnosed with cancer, but now palliative care is open to any patient who is terminally ill (Rosenwax et al., 2005). Its goal is not to prolong or shorten life, but to improve the quality of life for both patients and families, for as long as possible. Palliative care integrates physical, psychosocial and spiritual aspects to help patients to live as actively as possible until their
death, and to help family members during illness and pain. Hospital care includes palliative and curative care, but mainly focuses on curing patients.

It is important to emphasize a palliative patient is mostly more open than any other patient to discuss emotional problems more deeply (Hui and Bruera, 2016) and to reflect consciously about actions, decisions and their potential repercussions. Unfortunately, although the need to implement palliative care in patients is necessary and urgent, not all patients who would ‘profit’ from palliative care receive it (Meffert et al., 2016).

That said, we intend to introduce the idea that the subjective well-being of palliative patients could be fostered by means of design for wellbeing and in understanding the role of the environment as a place and as a multi-layered need. We will specifically elaborate about the possible ‘added value’ that architecture, interior architecture and industrial design can have in this respect. In our view, introducing this perspective would allow to work on issues that a traditional palliative care center does not seem to cover, and provide guidance for new approaches.

**Literature review**

**Design for wellbeing**

Inspired by ideas based in positive psychology, Desmet and Pohlmeyer (2013) aimed for positive design to be able to support human prosperity. Their approach promotes a change in vision in the design of new products, services and environments. The framework which they propose, takes into account three key components: (i) design for virtue (which encourages people to be a morally good person), (ii) design for personal significance (which supports people to pursue personal goals) and (iii) design for pleasure (intended to stimulate a pleasurable experience and diminish those who are not). Of these three components, the last is the one that is based on experiencing positive affect (positive emotions) when interacting, which means that a person having positive affective experiences will increase their perception of subjective well-being. Although it is not easy in practice, the ideal form of introducing these three aspects is to mix them together; yet, it is fundamental that at least one of these components is used to work on ‘Human Flourishing’.

Interior architecture may also have another way of promoting the subjective well-being of people in particular places, that is, by implementing the concept of attachment to a place: the emotional bonds formed between people and their physical environment (Manzo & Devine-Wright, 2014). When people live in a particular environment, they try to make a particular space their place; ‘a home’. In this line, Petermans and Pohlmeyer (2014) studied if and how interiors can be feasible to provide subjective well-being to people. There is also literature that shows that there can be an emotional bond between an object and a person (Schifferstein & Zwartkruis-Pelgrim, 2008), so they experience positive emotions towards the object, or experiencing a loss if this object is lost.
Design for well-being in palliative care

In traditional medicine, the palliative care approach is primarily aimed at mitigating physical pain, and although psychological support is provided to the patient, the main efforts usually are not aimed at relieving anxiety (Saunders, 2001). However, in recent years the perspective on health services has changed, taking a holistic approach, and all the factors that produce well-being for patients have begun to be considered as more important; that is, the physical factor, the psychological and the spiritual (Meffert et al., 2016).

People who are in the conditions of a palliative patient become much more receptive to environmental stimuli, so design becomes even more relevant. However, adequately designing the environment for terminally ill patients is only possible through in-depth knowledge of the psychological processes they are experiencing, in order to recognize their needs and wants (Golaet al., 2016).

There are different examples of how design for wellbeing has been successfully applied in the lives of human beings: Ruijs et al. (2012) found a way to transform a negative emotion into a positive experience in children's hospitalization. Miller & Kälviäinen (2012) proposed ways to improve the quality of life of both staff and residents in care homes, considering both the physical design and the design of caregiver roles and responsibilities. Chapman et al. (2012) focused on the design of new services and technologies to help with the management of type 2 diabetes. Barrera et al. (2014) designed a patient-centered innovation that engages all stakeholders and empowers patients to manage chronic diseases. These studies demonstrate that it is possible to aspire to an improvement in human life through design for wellbeing, which inspired us to reflect on how architecture, interior architecture and industrial design in particular can contribute to the wellbeing of people residing in palliative care.

A palliative patient's experience from a general approach

There are currently qualitative studies that discuss the death experience in terminal patients, which explore what is a ‘good death’ for patients and/or caregivers, or approach the issue from the perspective of the quality of death (e.g., Yao et al., 2007; Miyashita et al., 2008; Choi et al., 2013; Darer et al., 2015). In this respect, the quality of dying has been found to be a multidimensional construct, which includes physical, psychological, social, and spiritual experiences, term of life, preparation for death and circumstances about death, as well as the characteristics of health care at the end of life.

To date, research has demonstrated that the quality of death and dying, as well as the issue of experiencing a ‘good death’ (according to studies carried out with caregivers, doctors and terminal patients) is composed of the following characteristics, factors and descriptions:

(i) being free of pain, not with pain or symptoms of stress (Gott et al., 2008; Zimmermann, 2012; Dans & Sheldahl, 2015; Witkamp et al., 2015; Kamal et al., 2015); (ii) being free of psychological symptoms; have a good family relationship; being able to die in a place or environment that has been favoured (Yao et al., 2007; Gott et al., 2008; Hales et al., 2014); (iii) maintaining good relationships with the medical team, being able to discuss treatment with the doctor, having a nurse with whom one feels comfortable (Miyashita et al., 2008); (iv)
not being a burden on others, not having financial worries (Dans & Sheldahl, 2015); (v) to always maintain dignity and feel that you are satisfied at the end of life (Hirai et al., 2005; Miyashita et al., 2008); (vi) maintaining a sense of control (Hirai et al., 2005; Miyashita et al., 2008); (vii) having fought against the disease to its ultimate consequences (Hirai et al., 2005; Miyashita et al., 2008); (viii) keep hope (i.e., have something to spend the last days and that is enjoyable, live positively) (Hirai et al., 2005; Miyashita et al., 2008); (ix) not prolong life (Hirai et al., 2005; Miyashita et al., 2008); (x) being able to contribute to others (i.e., maintaining a role in the family or in occupational circumstances, feeling that one's life is worthwhile) (Goldsteen et al., 2006); (xi) having planned what will happen after death (i.e., having funeral planned, the last will) (Goldsteen et al., 2006); (xii) not being aware of death (i.e., dying while sleeping, dying without being aware that one is dying) (Gott et al., 2008); (xiii) thank and acknowledge others, be grateful to people (Witkamp et al., 2015); (xiv) maintain pride and having faith (i.e., feeling that one is protected by someone with a power beyond oneself, having religious beliefs (Choi et al., 2013).

The fourteen factors mentioned above can be compressed into three: (i) Acceptance of death: accepting death and being calm, free of psychological symptoms such as stress or anxiety; (ii) Physical symptoms and being free of pain (iii) Place and environment: the power to die or spend one’s last days in a favorite environment or place. It is in particular this third factor that opens opportunities to investigate the possible contribution that architecture, interior architecture and industrial design can have regarding the implementation of design for wellbeing in palliative care.

How to improve a palliative patient’s experience via design

After having investigated if design for wellbeing can be performed in the context of palliative care, in this section, we discuss how design can contribute to improving people’s experiences in palliative care. The three factors mentioned above are our guidelines in this respect.

(i) Acceptance of death
The fear of death in palliative patients may trigger a series of emotions that result in great anxiety, which in turn negatively impacts on their physical, psychological and social well-being. Anxiety is a fear that can take multiple forms. Generally, human beings face anxiety before death using the resources offered by our culture, although the reality is that most will spend much of their energies in denying the fact, in an effort to regain that control they have lost (Furer & Walker, 2008). The main problem of denial is that, no matter how much fear is attempted, anxiety will end up manifesting itself in a variety of symptoms such as worry, stress, depression and conflict (Yalom, 2008). Yet, positive oriented individuals who are motivated by their desire of having a meaningful life tend to cope better with denial of death (Wong & Tomer, 2011).

(ii) Physical symptoms and being free of pain
Pain is another key component to consider in the treatment given to patients in palliative care, since while pain is still present, it is very difficult for patients to feel comfortable. It is precisely here where design can generate support in a multidisciplinary field, since design can enable people to mitigate anxiety and pain (Jakob & Collier, 2016) which may generate the appropriate conditions for a holistic treatment (Ramadan et al., 2013), in physical,
psychological and spiritual realms. For that, design uses tools that can directly impact emotions, reducing the degree of anxiety and even mitigating pain.

In the domain of health, multiple studies have shown that exposure to a natural environment by means of biophilic design can provide relief from pain, and accelerate patient recovery. Biophilic design exploits the human need for nature and aims to provide a satisfying natural experience providing health and well-being (Kellert, 2008). In addition, it can also increase the morale of medical personnel (Kellert & Calabrese, 2015). Also, the use of windows that allow the contemplation of natural scenarios directly impacts the amount of analgesic medication needed by patients (Grinde, 2009). Such design not only impacts favorably on the health of the patient; it can also have repercussions on the relatives and medical personnel. According to studies, direct contact with plants in the workplace reduces the stress of medical personnel, while increasing their perception of satisfaction in the work environment (Ramadan & Heat, 2013). Dilani (2001) tells us that appropriate control of the environment through design generates a conducive means of directing energies towards social interactions; this helps to generate a low level of stress and strengthens the abilities of the individual to handle difficult situations.

Walch et al. (2005) conducted a study where the impact of sunlight on pain was determined in patients with spine surgery. According to the study, patients who were exposed to sunlight needed 22% less analgesic drugs, in addition to reporting a significant decrease in stress. Another finding was that patients exposed to sunlight have a shorter hospital stay. Diette et al. (2003) tested the effect of combining natural sounds and images in patients while undergoing bronchoscopy; these patients reported a significant increase in pain control. Another resource that showed its effectiveness, although difficult to use in the hospital environment, is water. It was demonstrated that using water as an element in design or even just integrating the sound of water, increased patient satisfaction levels (Grinde & Patil, 2009). Tse et al. (2002) induced pain to healthy patients who were exposed to a video of natural scenes, resulting in an increase in their tolerance to pain. These results indicate that the patients’ environment can be modified to influence the perception of pain, thus reducing the use of medications and their side effects. In the same way, an ‘improperly designed environment’ can be a source of stress, frustration and therefore affect health (Theorell & Arnetz, 2000). It is clear however that designers operate according to an ‘holistic’ approach of a particular environment, while taking into account different kinds of stimuli which can impact on the eventual ‘experience’ of a particular place.

Golembiewski (2016) argues that aesthetic changes in the design of an environment can improve patients’ health. Architecture can influence psychologically to improve or worsen their conditions, as it can have an effect on the neuroendocrine system of people. So, the use of design can have a significant impact on health care in general and palliative are in particular. In the case of palliative patients, who are exposed to very high levels of anxiety and pain, the use of biophilic design has proved to be an important adjuvant for the control of stress and pain, impacting not only on the patient, but also on their relatives and medical personnel.

(iii) Place and environment

Research shows that dying at home, where most patients want to die (Higginson & Sen-Gupta, 2000), brings higher quality of life (Wright et al., 2010). Therefore, dying in this place or a place that represents this quality within an environment may be associated with better
evaluations of the end-of-life experience than approaching one’s end in a hospital.

The place where death is experienced is related to the age of the patient, the time since (s)he has been diagnosed as a palliative patient, type of illness, how well the caregiver adapts to his or her tasks as such, and the issue of not receiving or receiving little assistance in palliative care (Hales et al., 2014). Research by Yao et al. (2007) showed that patients who responded better to their disease and who were clearly conscious regarding their diagnosis were those who preferred to die at home.

Life experiences have such emotional quality that they create a league with the places where this experience occurs. Also, attachment to a place has the potential to provide predictability in a daily routine, a place to relax from the more formal roles of life and the opportunity to control various areas of life (Low and Altman, 1992). According to literature regarding place attachment, the highest quality environments are those that support a person's goals and activities (Stokols & Shumaker, 1982). Applying such considerations to palliative care, it is clear that a patient in this type of environment will feel supported by living in a place where he has had the possibility to create a bond. Taken into account these considerations, one can understand why a person in palliative care often prefers to die at home or in a home-like atmosphere. Knowing about these factors allows one to control or adapt places to enable them to become a place to which a person can attach, and where a person can feel ‘at home’.

In summary, it is clear that a palliative care environment can be designed in such a way so that it allows patients to bring along objects they already know, as this can generate identity and place attachment. This enables people to experience a sense of belonging, control, self-esteem, meaning and security (Scannell & Gifford, 2016), so that the setting of the place where the palliative patient lives his last days can be composed of objects, artefacts and items, that refer to a place where they felt ‘well’. In this way, making such home-like environments for people in palliative care can enable them to intensify their well-being through the emotional, social and psychological characteristics that attachment to a place triggers.

**Discussion and Conclusion**

Following the above, it is evident that the use of design in the field of palliative care aims to provide the patient with wellbeing which allows him to face his last days with the greatest possible serenity, generating, as far as possible, an environment that allows to spend the last moments in the ‘best possible’ way.

Considering the importance of palliative care in recent years, it is our belief that design for wellbeing can be an inspiring approach to work on conditions so that patients in their last moments can ‘be well’ and be supported by design. Working on the interior architecture of palliative facilities can also be a resource of great help, since it would provide the patient with an environment that is familiar and where he can feel safe and calm. However, understanding patients’ experiences of death is difficult to achieve completely, so it is necessary to focus on gathering enough information to make the design of these environments as close as possible to what patients need and want. This is where the interest and creativity of a designer to find new ways, or adapt existing ones, is important. Finally, it should be noted that, although the concept of ‘the pursuit of happiness’ in terminal patients may seem rather strange or maybe even inappropriate at first sight, in the end, feeling ‘well’ until one’s very end is what most people long for. From our perspective, it is notable that both design, architecture and interior
architecture are capable of providing wellbeing to patients in these circumstances. Beyond the medical care and physical care that these patients need, it is necessary to remember that striving for wellbeing is something that can only be reached in a multidiciplinary context, in which design has a preponderant role. Applying a holistic perspective, while considering a system as an interconnected whole that is part of something larger, is key in this respect.

**Author Biography**

**Ammin Gil Huerta**

Ammin obtained her Master degree in Industrial Design at Universidad Nacional Autónoma de México, at the Faculty of Architecture. She currently works as interior designer. Her research interests are on design for subjective well-being, especially for palliative care, and designing for experiences.

**Ann Petermans**

Ann holds a Ph.D. in Architecture and is affiliated to the Faculty of Architecture and Arts of Hasselt University, Belgium. Her research interests pertain in particular to designing for experience in designed environments and for diverse user groups, and research related to design for subjective well-being in architecture and interior architecture. Ann is co-convenor of the DRS’s Special Interest Group on Design for Wellbeing, Happiness and Health.

**Jan Vanrie**

Jan obtained a PhD in Psychology (University of Leuven) and is currently an associate professor at the Faculty of Architecture and Arts of Hasselt University (Belgium), where he teaches courses on human sciences and research methodology to spatial designers and
coordinates ArcK, the research group for architecture and interior architecture. His own research interests are on Designing for More, perception, environmental psychology, (design) research methodology and education in (interior) architecture.

Tiiu Poldma

Tiiu holds a PhD in Interior design education. She's currently a full professor, teacher and researcher at the Faculty of Environmental Design at the University of Montreal. She won the title 'compagnon de Ferdie', for her work in raising the quality of teaching and promoting excellence in professional interior design. She teaches the importance of integrating design with concern for the well-being of the population being served, particularly vulnerable populations such as children and older persons.
Design sprints and substance: Assessing the spectrum of design education opportunities for non-designers

Bruce Hanington, Carnegie Mellon University School of Design, Pittsburgh, USA hanington@cmu.edu

Abstract

Design education opportunities for non-designers are abundant and growing, many offered as rapid sprints through executive education style workshops or online courses. While these quick immersions may serve to infuse design thinking into the work processes of other disciplines, there is a risk of oversimplification. How can courses impart an appropriate sense of design without minimizing its complexity? What are the essential components of design, and optimal timing and formats needed for meaningful delivery? On the other hand, how can we educate those who seek a robust design complement to their existing professions, and those seeking a full transition of their careers into design practice? This study looks at the inception and early iterations of a one-year degree program providing an in-depth education to non-designers seeking a complementary education to other credentials or a full conversion to design through modular degree options. The first years of the program suggest several findings. For example, interdisciplinary cohorts introduce a mix of rational and intuitive approaches. Students need mentorship into design processes and practices, such as subjectivity in assessments and feedback through critique. Educators are challenged to acknowledge the past education and professional backgrounds of students, capitalizing on their unique strengths rather than homogenizing all students into a singular version of design. Students need tools to assess their professional identity during their transition to design. This work in progress will examine the spectrum of design education opportunities for non-designers, including key factors differentiating a degree program from the proliferation of short course exposures.

Keywords: design, non-design, executive education, graduate, pedagogy.

Design and design thinking has become prominent everywhere. Design processes are promoted as a tool for enhancing creativity and innovation in the workplace. A plethora of opportunities are presented to infuse design methods into professional business practices, or into other areas as diverse as healthcare, education, and public policy. Forms of delivery range from intensive workshops, short courses and webinars, through to certificates and design degree programs.

However, given this proliferation of opportunities, it can be difficult to parse the difference between design offerings as significant adoption, tangential exposure, or misused buzzword. How can courses impart an appropriate sense of design without minimizing its complexity? What are the essential components of design, optimal timing, length, and formats needed for meaningful delivery, depending on the intended purpose by those delivering curriculum, and the goals of audiences seeking a design education?
On the one hand, executive education and short immersive workshops offer an opportunity for efficient exposure to design principles and methods, which may be enough for adoption by those primarily immersed in other forms of work. These formats also may be the only realistic way for busy working professionals to gain sufficient experience within a limited amount of time. On the other hand, those who want to understand the significant complexities of design to competently engage in the practice of design methods and processes will need more education, through either longer or deeper exposure, or ideally, both. And finally, those seeking to fully convert to professional design careers from diverse backgrounds need a comprehensive pathway for this transition.

The Carnegie Mellon University (CMU) Master of Arts (MA) in Design offered by the School of Design is a one-year intensive program attracting three different primary cohorts of students.
First, those seeking a robust design education complementary to their existing qualifications commonly return to professions or transition to new careers with an infusion of design methods, tools and processes to enhance work that is not primarily characterized as design. Second, those seeking to convert their current backgrounds or careers to become professional designers utilize the MA as a prerequisite to continue through the Master of Design (MDES) or Master of Professional Studies (MPS) degrees offered by the School of Design, thus graduating with a terminal credential. Third, a small subset of students use the MA degree as a point of entry into other related degrees, at CMU or elsewhere. The MA in Design program does not, in itself, claim to qualify graduates as designers, clearly positioned as a complementary degree to other professions or as a prerequisite for further design study.

Students enrolled in the MA program span a full diversity of backgrounds, including the social sciences, sciences, and engineering, liberal and fine arts, humanities, and education. Some remarkable examples include an archaeologist, a dancer and choreographer, a language translator, a kindergarten teacher, a florist and wedding planner, a medical illustrator, and a comic book artist, with degrees ranging from anthropology, computer science, business, and chemical engineering, through to philosophy and mathematics, peace and conflict studies, and East Asian studies.

The structure of the MA is predicated on a two-semester sequence, with broad exposure to design fundamentals followed by a more focused introduction to interaction design. First semester coursework consists of a visual communication fundamentals studio paired with a software lab, an introductory seminar on design thinking, and a design principles and practices course. The second semester studio provides an introduction to interaction design paired with a prototyping lab, complemented by a seminar on transition design, and an open elective. The transition design seminar examines design as a potential catalyst toward socially and environmentally sustainable futures (Irwin, 2015).

This paper presents a work in progress. A brief review of literature and precedents will summarize some of the current thinking on educating non-designers, followed by an overview of methods used to assess the MA Design program and other forms of educational delivery. This background summary will then lead to a discussion of the spectrum of potential opportunities in design education for non-designers, outlining the relative merits of various
formats through comparison and contrast. Several key findings will be identified, particularly through ongoing review of the MA program. As this work progresses, the goal is to identify essential elements of design, with timing and formats for meaningful delivery that are effectively and sufficiently comprehensive for a given audience and context.

**Literature Review**

Despite the abundance of educational opportunities, there is a limited body of literature dedicated to the study of design education targeting non-designers. In 1982 Nigel Cross presented work on fundamental ways that designers think and practice (Cross, 1982), ultimately building toward his landmark book on design thinking (Cross, 2011). Texts on the essence of design include the collection of How Designers Think (Lawson, 2005); What Designers Know (Lawson, 2004), and Design Expertise (Lawson and Doorst, 2009). Many of these sources are essential reading for designers, yet would likely have a limited readership among non-designers, unless assigned as part of a formal design education.

Several references target a wider, specifically non-design audience for applications of design thinking, typically in business (e.g., Kunitake, 2017; Lockwood, 2010; Brown, 2009). Still other sources focus on providing technical design skills to non-designers (e.g., Williams, 2015). Others have attempted to demystify how designers think and practice (Kolko, 2015), or explain the differences between design and non-design communication (Drysdale, n.d.). In describing his materials, Drysdale states, “Non-designers will learn the important parts of design, so that you can understand what designers do, achieve your goals, and better communicate your ideas.

Designers: learn to teach and guide others through your design process so they'll better appreciate what you do.” Carrying this one step further, some authors have explicited how to train non-designers on design thinking, with a goal of building more effective teams (Seidel and Fixson, 2015). These lessons have also been the subject of conference papers and workshops (e.g., see Miller, 2015).

However, formalized study of the education of non-designers on design is limited. In 2009 Anne Burdick espoused a view of design that included an analysis of what non-designers (and designers) see in design, as determined through a series of case studies of university programs (Burdick, 2009). Aspects of design seen by non-designers include thinking, making, artifacts, tools, methods, and studio as a model of collaborative working. These terms are further parsed under design as a research paradigm, a way of learning, a mindset, and as literacy. Burdick cautions against a reductive commercial definition of design in business terms, advocating instead for the empowerment of design as “shaping culture, knowledge, and the human-made world, including commerce.” (p. 13).

In a 2013 conference paper, Morehen, Wright and Wrigley presented a case study detailing how an immersion workshop curriculum can play a role in developing design thinking and innovation capabilities in non-designers, including “problem solving, collaboration, adaptation, entrepreneurialism, oral and written communication, critical analysis, and imagination.” (p. 56). Results highlighted common issues of communication and professional language barriers; ambiguous project definition and non-designer tendencies toward solutions
over process; acceptance of failure as part of learning; and challenges and benefits of working in multi-disciplinary collaborative teams. The study also noted “a global lack of evidence-based research regarding the perceived value and role of professional designers in teaching design thinking and design led innovation processes to non-designers.” (p. 62).

Research Methods

A variety of methods were used in assessing the CMU MA in Design program and other design offerings in this ongoing study. Informal feedback was offered by and collected from students during teaching of a required course, Design Principles and Practices. At the end of the first run of this course, a voluntary survey was issued to all students enrolled. Feedback on this course was also provided through formal Faculty Course Evaluations (FCEs) mandated by the University. Limited access to course evaluations for other classes was taken into account. Email correspondence and in-person conversations with students provided further feedback on the MA program, through my advising capacity as Director of Graduate Studies. Ongoing discussions were held with a core of faculty colleagues who were instrumental in developing and delivering the MA curriculum. Confidential exit interviews conducted with all graduating students by a graduate program coordinator provided a final measure of input.

In assessing the range of other forms of educational delivery, an informal audit was conducted of a sample of executive education offerings, as well as short courses, workshops, and webinars delivered by both corporate entities and academic institutions. Information was collected from websites and other forms of promotional materials, examining key common variables such as length of time, themes, target audiences, and cost. These examinations were supplemented with several first-hand experiences teaching executive education workshops, both to other entities within the CMU campus environment, and to outside participants from various organizations. In summarizing executive education offerings, the focus was on general courses such as design thinking, rather than specific skills training. Programs similar to the CMU MA in Design, i.e., degree-granting programs aimed at or accepting students with non-design backgrounds, were also considered.

Future research should include an expanded number of assessed offerings, as well as surveys, interviews, and other forms of direct information collection from administrators, instructors, and student participants, representing this range of programs.

Discussion

Findings from assessments of the MA program begin with student motivations for entry into the degree. Whether they were approaching a conversion of their career to design or adding a design complement to their existing credentials, many have very specific goals. As one student indicated, “I originally came to CMU because, when working at an art museum, I asked myself who in the museum I would most like to trade places with. Hands down, I wanted to do what the UX designers at the museum were doing.” Other common motivations that attracted students to design included collaborative work in interdisciplinary teams, an emphasis on action with visible impact versus theory, the design process, skill building, and employment potential. As articulated
by one student, “I needed a process - from taking ideas, sorting through them and picking the good ones and moving them forward. Design has taught me those things and I feel prepared now in any setting to be a better communicator and make things come to fruition.” Significant findings arose in three areas: student backgrounds, forms of evaluation and feedback, and applied skills.

Although they recognized the need for intense design education, students wanted their prior backgrounds to be respected. It was critical to many that rather than being homogenized as a singular version of designer, that their unique undergraduate education and work experience in other fields be acknowledged, and guidance provided on how they might integrate these backgrounds into their emerging design education and future careers. In one instance, a seminar instructor proposed that a challenging question within a classroom discussion would be better answered by an anthropologist, overlooking that there were students with anthropology degrees in the room. Others saw the potential of merging their past credentials with design to forge new and powerful careers, yet felt ill-equipped to navigate this trajectory or position themselves on the job market alongside competing portfolios aimed at commonly sought-after skills. Students claimed a need for a combination of guided self-reflection and mentorship to see them through this process.

Second, depending on the backgrounds from which they came, many students need help in understanding design approaches to feedback and evaluation of work. Those transitioning from disciplines that operate from a rational or empirical model may feel uncomfortable with the subjective forms of critique common to design, and may expect more rigorous criteria and regular checkpoints to determine if their work is proceeding according to expectations. While some of these results suggest the need for explicit guidance in transitioning non-designers from rationally-based disciplines to some of the more intuitively-based aspects of design, it also suggests that design educators could often times be more clear in their articulation of criteria for grading and feedback, and communication of project assessments.

Third, students appreciated the practicality of hand skills, and applied principles and practices of design. This has implications for degree and long-term programs, as well as executive education. For degree programs, students obviously need the requisite skills to be able to perform well within their coursework, and to present themselves competently on the job market through their portfolios. However, we have also learned in the delivery of executive education, that participants from almost any background with any goal appreciate the simple confidence given to them through even a basic drawing workshop, exposing them to the essential tools and techniques of visualizing to document observations, and to generate and communicate ideas.

Programs competing with the CMU MA in Design in the university market include a similarly based intensive education in design. The curriculum at Illinois Institute of Technology (IIT) Institute of Design (ID), for example, offers a nine-month (two-semester) foundation program in design for students entering the Master of Design (MDES) without a design background. Likewise, for non-designers entering the two year MDES at University of Washington (UW), the school offers “a three-year course of study that emphasizes mastery of core design skills while pursuing graduate-level study.” In these two examples, a two-year degree
becomes a three-year degree with no additional credential granted. While this simplifies things administratively, it provides no opportunity for a standalone credential, awarded to those who only want the one-year intensive to add to their qualifications or to apply within other careers, or to use as a stepping-stone to other programs.

Other degree programs admit non-designers and designers alike, into the same program, with no additional time required for non-designers. The Master of Integrated Innovation in Products and Services (MII-PS) at CMU admits students from design, business and engineering, and cross-trains in the three disciplines. UW offers a Master of Human Computer Interaction and Design (MHCI+D), attracting a diverse cohort from across design, technologies, and other disciplines. The School of the Visual Arts (SVA) has an MA in Design Research, Writing, and Criticism inviting applicants from various backgrounds. The one-year MA in Social Design at Maryland Institute College of Art (MICA) attracts a wide range of applicants, as does the social-change oriented Austin Center for Design (AC4D). These programs provide a rich context for study with an interdisciplinary mix of students, particularly when structured around team projects.

However, there are ambitious challenges to providing an equivalent experience and end-qualification to cohorts of both designers and non-designers alike, especially within such a limited time.

An alternate model offered by both the Stanford d.school, and Northwestern University Segal Design Institute, provides design courses for the campus at large, as well as to working professionals through public workshops and executive education. The courses open to the wider campus allow students studying in various fields to add design components to their education on an ongoing basis, infusing design thinking and skills into their emerging professional credentials and practice. Stanford further categorizes their offerings into core, boost, and pop-out classes.

Core courses represent immersive and comprehensive courses; boost courses are quick skill-builders, and pop-out courses are activity-based weekend workshops. Northwestern offers introductory courses in human-centered design, intermediate courses, capstone courses, and featured courses in specific topics. Some sequences of courses can lead to a Segal Design Institute certificate.

Factors differentiating executive education and other short-course offerings include institutional or corporate affiliation, target audience, key themes, duration, mode of delivery, and cost (see Table 1). The largest target audience appears to be business, broadly defined across other terms including leadership and team management. Key words most frequently occurring in program and course materials include design thinking, problem-framing and problem-solving, team collaboration, innovation, and human-centered, user-centered, or customer-centered design.

Much of the material is then sequenced through the “design process” variously described, with some including elements of prototyping and other forms of hands-on making. Some courses offer a particular focus, such as service design, social design or sustainability. There are a large number of both on-site and online and webinar-based courses, ranging in time from 90 minutes to several weeks. Cost ranges from free, to several thousand dollars.

Note: In 2014 Northwestern University in collaboration with Bruce Mau and the Massive Change network offered an executive education short course called “Design for Non-Designers” described as “an immersive, hands-on experience introducing non-design professionals to the practice of using design thinking as a strategic tool for innovation.”
Conclusion

Executive education and short course workshops could benefit from a study of new and established degree programs, to better understand the key ingredients of a thorough, robust design education. Even if these essential elements are not possibly delivered with the same depth and rigor afforded through longer credentialed education, the subject matter and methods may provide relevant insight into content and delivery. These essential elements will of course vary by design profession and for each intended audience. However, some basic tenets of design would be contextualizing problems before seeking solutions, adopting a human-centered approach (including participatory design and testing of ideas), interdisciplinary collaborative teamwork, combinations of creative divergent and convergent thinking, visualizing to explore and communicate shared ideas, and iteration and critique. Further contextualizing an executive education course or workshop as a sprint, and acknowledging the deeper education undertaken by professional designers, would help convey respect for the profession of design.

While the longer education and a credential offered by a degree program sounds like a preferred option for those who can afford the cost and time, there are elements of executive education and workshop formats that are better suited to the audiences they serve. Furthermore, for those still exploring the potential of design, whether as a complement to or conversion of their existing career, shorter educational opportunities allow them to understand more about the field before deciding to make a significant investment of time and money into a degree program. By referencing degree programs, students of short courses would better understand the context of their abbreviated exposure, and could investigate the longer opportunities if they were interested. Based on the findings of the MA program assessment, for example, students could begin to map their journeys from past and current backgrounds, to their experience with design, and to a desired future career.

Additionally, many of the elements of executive education could be beneficial within a degree program. For example, the short intensity of workshop formats could be integrated as a series of exposure points within a longer program. With a more agile degree program subject matter could be more easily kept relevant as the world changes, in contrast to the investment that goes into crafting a full semester course for longevity. Short workshop formats within a degree could contribute to a more dynamic and active curriculum, and, could create a more professional- friendly schedule with greater flexibility for those navigating full time work and part time studies. A restructuring of a degree program into flexible modules may furthermore resonate and provide opportunities to a wider diversity of people. And finally, the content of executive education courses may highlight relevant topics from current design practice that should be included in mainstream classroom and studio curricula.

Bruce Hanington

Bruce Hanington is an Associate Professor, Director of Graduate Studies, and former Program Chair of Industrial Design in the School of Design at Carnegie Mellon University in Pittsburgh, Pennsylvania. His core teaching includes How People Work, Research Methods for Design, Design Principles and Practices, and The Meaning of Form. Bruce has dedicated his work to methods and practices for human centered design. He has recent chapters in The Routledge Handbook of Sustainable Design, and Emotions and Affect in Human Factors and Human-Computer Interaction. Bruce is co-author of the book Universal Methods of Design: 100 Ways to Research Complex Problems, Develop Innovative Ideas, and Design Effective Solutions (Rockport 2012; Pocket Edition 2017). He holds a BA in Applied Psychology and a Master of Environmental Design (MEDes) in Industrial Design from the University of Calgary, Canada.
Easybottle: A study of metaphor in interaction design
Jeemin Han, Youngsik Cho, Ewha Womans University, Seoul, Korea, jeemin423@gmail.com

Abstract

Lately, various kinds of intelligent products have been invented, and to play a part in the “intelligent” era, I designed an intelligent nursing bottle which can help a user when making up a bottle for a baby in middle of the night. The intelligent nursing bottle, Easybottle is a behaviour induce interaction product, which means that it motivates a user to do something with pleasure. As a mother of one year old, I learned that it is very important for a caregiver to feel satisfied in order to nurse a baby from the heart. Easybottle provides sound modality to notify the caregiver how much water she should pour when mixing powdered formula with water so she does not need to feel agitated to read bottle markings in middle of the night when her eyes are not fully awake.

The methodology that I applied is metaphor. As metaphors, I chose two different sounds to compare; sound of water pouring and sound of a car’s proximity sensor. The main goal was to define more useful interface for Easybottle.

I conducted quantitative within-participants experiment. This study explored whether lifelike sound works better or artificial sound works better as an indication interface. Participants evaluated the water pouring sound interface more positively than a car’s proximity sensor sound interface. Lifelike and hedonic factor appeared to be attractive to the participants and it implies that even though Easybottle is an electronic product, participants appreciate more when it reminds them of nature. Also, entertainment factor is important when doing a chore.

Keywords: Design strategy, interaction, interface, user experience
Introduction

Background of the Study
Lately, various kinds of intelligent products have been invented, and to play a part in the “intelligent” era, I designed an intelligent nursing bottle which can help a user when making up a bottle for a baby in middle of the night. The intelligent nursing bottle, Easybottle is a behaviour induce interaction product, which means that it motivates a user to do something with pleasure. As a mother of one year old, I learned that it is very important for a caregiver to feel satisfied in order to nurse a baby from the heart. Easybottle provides sound modality to notify the caregiver how much water she should pour when mixing powdered formula with water so she does not need to feel agitated to read bottle markings in middle of the night when her eyes are not fully awake.

Objective of the Study
The objective of the study is to determine more effective sound interface for Easybottle. Two sounds were compared in the study; water pouring sound and a car’s proximity sensor sound. Water pouring sound is used as an example of a lifelike sound, and a car’s proximity sensor sound is for an artificial sound.

Related works

Intelligent Products
An intelligent product is a robotic product in which information and robotic technologies are integrated into an existing common product\(^1\). Intelligent products can understand, decide, and act according to the environment\(^2\).

---

In order to design an intelligent product, the product which needs to be redesigned need to be analyzed thoroughly to extract elements that could be fixed or improved. When parts to be reformed are defined, the designer can choose how it should be enhanced using sensors, such as a light sensor, a pressure sensor, a humidity sensor, etc.

In this study, a nursing bottle was chosen to be improved and light sensors were used as enhancements. I focused on milk pouring action into the nursing bottle. Especially at night, I always had hard time reading the gradient marking on the nursing bottle, so I had to bend my body forward and lower to read the marking on the nursing bottle which is on my kitchen counter while my hand is above my head, still pouring the milk into the bottle. It got me thinking how easy it would be if I could pour milk to the point without looking at the markings. This thought lead me to design a bottle that notifies the bottle marking with sound.
Metaphor

“Metaphor” allows designers to design products through more effective process⁴. The word, metaphor was originally used in Linguistics. A metaphor is the expression of an understanding of one concept in terms of another concept, where there is some similarity or correlation between the two⁵.

Conventional metaphor is used for communication or academic purposes. In contrary, conceptual metaphor is used very often to understand theories and models. It uses one idea and links it to another to better understand something⁶. Because of this attribute, conceptual metaphor is useful for designers to develop a new system or concept, and metaphors that are discussed in this paper are conceptual metaphors.

Domain Distance Theory of Metaphor claims that it is attractive to an audience when between-domain distance is far and within-domain distance is close. Jung interpreted that farther the between-domain distance is, the more the audience gets interested. However, when within-domain distance is close, the metaphor makes sense to the audience. Close within-domain distance means that attributes of source element and target element are somehow similar.

Two sounds that I decided to experiment with are water pouring sound and a car’s proximity sensor sound. A car’s proximity sensor is somehow similar to pouring milk up to a point because it notifies when to stop. And the between-domain distance is far because one is driving a car and the other is pouring milk into the bottle.

Between-domain distance of water pouring sound is not very far because the only difference is types of liquid that is being poured into the bottle. Within-domain distance is definitely close as they both are liquid that are pouring into bottles.

According to the Domain Distance Theory, a car’s proximity sensor sound interface, Bibeap should be more attractive to users, however lifelike sound has always been appealing to users. It was very interesting to observe which factor is more tempting to the users.

Hypothesis

The sound interface of an intelligent product is more effective when it is a lifelike sound than an artificial sound.

Study Design

The experiment is designed to compare lifelike sound interface and artificial sound interface. Water pouring sound was used as lifelike sound interface (Pokpo), and beeping sound was used as artificial sound interface (Bibeep).

Participants

Thirty-six people aged from 15 to 85 (twelve males twenty-four females) who live in Seoul Korea participated in the study.

Materials

To begin the experiment, I built the interface using LittleBits\(^7\) which is very useful in the beginning stage of the design process. Two light sensors and two mp3 players are used in the first prototype. The LittleBits circuit is shown as figure 1, and two sets were used in the prototype.

\(^7\)LittleBits makes a platform of easy-to-use electronic building blocks empowering everyone to create inventions, large and small. The description is from https://littlebits.cc
Two light sensors are allocated vertically so when the lower light sensor is triggered, the mp3 player plays repeated short interval beeping sounds, and when the higher light sensor is triggered, the mp3 player plays a continued beeping sound.

The first prototype was used for a pilot survey and based on this survey, I built a developed version with Arduino IDE. In this version, I added one more light sensor to be triggered when milk pouring starts. When milk pouring starts, either water pouring sound or beeping sound will start.

I designed the sound interface in three-steps. As for Pokpo interface, water pouring sound begins when the participants start pouring the milk, smaller volume of water pouring sound will play as milk reaches the middle point, and when it reaches 160ml point, water dropping sound will play to imply to stop pouring the milk. For beeping sound interface, longer interval beeping sound begins to play when the participants start pouring the milk, shorter interval beeping sound will play as it reaches the middle point, and continued beeping sound will play when it reaches 160ml point to signal to stop pouring the milk.

For the first prototype, I used cellphone flashlight to provide light as the light source for, but for the later version, I embedded red LED lights for the light source.

![Diagram of sound interfaces](image)

Figure 4: Water pouring sound interface, Pokpo, and a car’s proximity sensor sound interface, Bibeep.

**Procedure**

Participants were welcomed to the lab and were instructed to pour milk into nursing bottle twice, once with Pokpo interface and another with Bibeep interface, in random order. After participants poured milk into nursing bottle with each sound interface, they filled out questionnaires.
Measures

In the first part of the questionnaire, I asked usefulness of the interface, and product evaluation. Usefulness of interface is for dependent measure, and is an index of two items, “I think this nursing bottle is useful to me” and “It would be convenient for me to have this nursing bottle”. The index is very reliable (α = .957). Product evaluation is an index of four items. The four items are “very bad / very good,” “very poor / very excellent,” “very negative / very positive,” and “very unfavorable / very favorable.” The index is very reliable (α = .969).

In the second part of the questionnaire is composed of questions asking about purchase intension, orientation between utilitarian and hedonic, animacy, machinelikeness and behaviour induce product. Purchase intension is an index of two items, and they are “How much do you wish to purchase this nursing bottle?” and “How much do you really wish to purchase this nursing bottle?” The index is very reliable (α = .979). The orientation is an index of four items. The items are utilitarian/hedonic, useful/fun functional/pleasant, and assists to accomplish one’s purpose/gratify one’s senses. The index is very reliable (α = .944).

For manipulation check measures, degree of animacy is measured by using the six items; dead/alive, stagnant/lively, mechanical/organic, artificial/lifelike, inert/interactive, and apathetic/responsive. The index of animacy was very reliable (α = .913).
Results

The statistic shows that the participants felt Pokpo is more useful than Bibeap (M_{water}=5.78, SD=1.32 vs. M_{beep}=5.43, SD=1.42; t=1.745, df=35, p< .05). The participants wanted to purchase Pokpo more than Bibeap (M_{water}=4.97, SD=1.72 vs. M_{beep}=4.64, SD=1.87; t=1.307, df=35, p< .1). Even though the result is marginally significant, I decided to include in this paper. The participants thought Bibeap has more

---

utilitarian aspect than hedonic aspect, and Pokpo has more hedonic aspect utilitarian aspect (M\text{water}=4.17, SD=1.93 vs. M\text{beep}=3.26, SD=1.86; t=4.040, df=35, p< .0001). Also, they felt Pokpo was more lifelike than Bibeap (M\text{water}=5.32, SD=1.06 vs. M\text{beep}=4.32, SD=1.73; t=3.674, df=35, p< .0005). Obviously, Bibeap was more machinelike than Pokpo (M\text{water}=4.03, SD=1.54 vs. M\text{beep}=5.50, SD=1.42; t=4.751, df=35, p< .0001). Participants felt Pokpo induces their behaviour more than Bibeap (M\text{water}=5.08, SD=1.52 vs. M\text{beep}=4.70, SD=1.75; t=1.290, df=35, p< .1). The hypothesis was supported by the data.

**Interpretations of the Results**

Participants evaluated the water pouring sound interface more positively than a car’s proximity sensor sound interface. Lifelike and hedonic factor appeared to be attractive to the participants and it implies that even though Easybottle is an electronic product, participants appreciate more when it reminds them of nature. Also, entertainment factor matters when doing a chore.

**Limitations**

There are some limitations to this study. First, milk was used in the experiment instead of powdered formula and water as it would be in a real situation. I would like to conduct an experiment with powdered formula and water to mimic the real situation in the future. Second, all the participants were from Seoul Korea. Future studies could include participants from different backgrounds and cultures. Third, the experiment was evaluated also by people who has never nursed babies. In the future studies, I would like to recruit people who is currently nursing babies younger than a year to examine the usefulness of the Easybottle. Lastly, the experiment did not include a section to examine the Domain Distance Theory of Metaphor due to complication. I would like to focus on proving the relation between water pouring sound and beeping sound, and domain distance of metaphor in my future studies.

Design Infrastructuring Toward A Utopian Economy

Maryam Heidaripour, Institute of Design, Illinois Institute of Technology, Chicago, USA, maryam@id.iit.edu

Abstract

The political rhetoric of today economy has framed innovation as reproduced and reserved by specific people in specific locations. This framing has shaped the discourse of who is deserving and who is not deserving and gradually sets the foundation of social discrimination, inequality, and exploitation as part of the neoliberal economy. Given the claim that entrepreneurs are inventing the future, this paper envisions alternative futures in which performing economy contributes to socio-technical transformation. To that end, this paper focuses on two community-based initiatives in Chicago that their contribution to economy is not recognized due to incompatibility with mainstream narrative. In these counter-hegemonic exemplars, different but potentially related future-making practices occur; they are shifting the emphasize from individual entrepreneur to a collective economic development and moving forward the discussion of entrepreneurship to the kind of society and the kinds of citizens that it is creating. By conducting ethnographic study on these exemplars, patterns have emerged that are informative to design strategies for infrastructuring and socio-material negotiations.

Keywords: alternative economies, infrastructuring, entrepreneurship, futures, community engagement

This research attempts to challenge the neoliberal takeover of entrepreneurship. Obsessed with innovation, neoliberal societies are supporting policies of privatization, deregulation, trickle-down economics to pave the way for the next revolutionary and disruptive technological change. But the overlooked aspect is the increased insecurity of workforce along with hard work and low pay (Sennett, 2006; Neff, 2012; Derickson, 2013). A case in point, Silicon Valley, a globally recognized center of innovation and entrepreneurship, is infamous for having a bell curve wage gap that has created a servant/master dichotomy. By recognizing that the hegemonic model has set the foundation for inequality and discrimination, this research proposes a list of principles for infrastructuring toward the realization of an alternative mode of economy. Infrastructuring is an unfolding process of socio-material negotiations to handle controversies by aligning norms and values (Star & Bowker, 2002; Karasti et al., 2010). In design, infrastructuring has been specifically investigated for the realization of democracy and formation of publics around matters of concern (Ehn, 2008; Björgvinsson et al., 2010; Le Dantec & DiSalvo, 2013). Along with the same lines, this research aims at using infrastructuring as a set of strategies to increase awareness around the issues of neoliberal economy and encourage discussion among community members toward the realization of an alternative model.
Background

Entrepreneurship is socially constructed as a masculine experience associated with white mentality, which reproduces the stereotype of women and communities of color as ignorant and incapable in the field (Weber, 2006). This socially constructed of abilities leads to discrimination in access to entrepreneurial resources, which in turn contributes to segregation in the startup index (Popescu, 2012). To illustrate, Wadhwa, et. al., (2009) counted the ways in which systematic or hidden biases in the venture-capital industry filters out minority groups from access to finance. They claim that venture capitalists invest in people who fit into the “pattern” of successful founders, openly identified as “white, male, under 30, nerds, with no social life who dropped out of Harvard or Stanford”. In this stereotype of successful founder, women and many other categories of people are overlooked. Such hidden biases lead to conformity in the community of entrepreneurs that negatively impacts innovation. But more importantly, it raises the question of “how the world is designed and for whom” (Wajcman, 2007). In other words, by marginalization of many groups from entrepreneurial activities, entrepreneurs are “inventing” a future¹ that is not compatible with the fabric of the society.

On the other hand, narrow characterization of entrepreneurs negatively impacts the economy of cities with diverse population. A case in point, in 2013 Chicago unveiled its Tech Plan as an extensive strategy to attract technology companies and provide them the best infrastructure to grow and succeed in order to achieve citywide economic growth and prosperity². Although in 2016 venture capital investments increased almost double compared to 2015 and Chicago was named the nation’s top city for return on startup investment (DJX VentureSource, 2016), its startup growth rate for the same timeframe dropped from 25th to 30th among metropolitan areas in the nation (Morelix, et. al., 2016). Although several contributing factors exist, conventional wisdom holds that economic growth requires population growth and the Chicago area had the greatest population loss of any major city in the nation in 2015 (The United States Census Bureau, 2015). Although the Chicago Tech Plan will create job opportunities for qualified candidates in high-end tech/service industries, it eliminates the need for many middle-class jobs that are dominant in a city with roots in the industrial age. Therefore, in spite of investments, Chicago’s unemployment rank 46 among 51 large metropolitan areas in the United States (Bureau of Labor Statistics, 2016-B). Marginalization of people from entrepreneurial activities by sorting the city resources toward high-tech innovation startups that are incompatible with many residents’ skills and experience. This issue again shows the importance of promoting more diverse categories of entrepreneurs and considering alternatives to the dominant model.

¹ The motto of Xerox Park in Silicon Valley, Invent the Future, has become a virtual mantra: you can’t predict the future, but in Silicon Valley you can “invent” it.
Research Questions

The goal of this research is to create a new myth for a plural form of economy to increase participation of more diverse groups in entrepreneurial activities and to create conditions for them to succeed. This new narrative will respond to the dystopian version of the future in which

the majority of the labor force will lose their economic role due to automation; the new narrative will include today’s capabilities and motivations of marginalized entrepreneurs and unleash their potential by utilizing new relationships and values. In the new narrative, diverse people can contribute to a more dynamic version of economy, and their participation will be a whole new mode of performing entrepreneurship as a common part of a larger ecosystem. To achieve this objective, number of research questions were raised. These include: How are the alternative models of performing economy different from mainstream model? What are the factors that help them to succeed? What kinds of skills, values, and relationships are unique to them? What are the values embedded in their activities? What is the role of existing alternative models in shaping the economy of their locality and creating a cohesive community vibe? How might values around innovation and entrepreneurship be further embedded in their culture of innovation? What could be a new mode of entrepreneurship inspired by them? How can we design infrastructure to promote this mode of entrepreneurship among women?
Methodology

This study started with an extensive literature review to conceptualize issues that form the basis of this research. This also created a set of criteria to evaluate the findings. In addition, during the last year, two studies were completed. In order to address the research questions and design a new narrative for the future of economy, this research looked at initiatives that are already engaged in extraordinary social, cultural, and environmental entrepreneurial activities in Chicago, even if they are not generating revenue. This allows for analysis into how their values are translated into skills, motivations, and challenges, if not revenues. One was the Read/Write Library, an entirely volunteer-run nonprofit organization that preserves community media. Along with interviewing its founder, staff, board members and visitors, participant ethnography was conducted by participating in their monthly book club meetings, volunteer gatherings, and workshop preparation sessions. During the study period, library also ran three BiblioTreka events, and a four-month-long exhibition at the Hyde Park Art Center that were both included as data gathering sites. A lot of infrastructure related needs were discovered along with insights that can potentially inform community organizing activities. The second was the Coder Space, a nonprofit organization where African American teenagers were taught to code, collaborate on local client projects and develop leadership skills for a digital world. It was a four-month participant ethnography of their weekly meetings, interviewing founder, teachers, volunteers, and students.

In addition, the researcher took the role of facilitator for their weekly sessions in which students democratically participated in envisioning the future of Coder Space, exploring its marketing strategies, and expanding community engagement activities. Both of these initiatives are probably closest to von Hippel’s user innovation with the two advantages that Benkler (2016) counts: they have “localized, contextual knowledge of needs, and high degree of practical experimentation”. But more importantly, they were chosen as excellent examples for this research due to their potentiality to reframe economy as a discursive construct that can be reconstructed to contribute to social transformation (Cameron & Gibson-Graham, 2003). In other words, to move forward the discussion of entrepreneurship to the kind of society and the kinds of citizens that they were creating.

---

2 More information on Chicago Tech Plan is available at: http://techplan.cityofchicago.org/. It is the first-ever comprehensive technology plan in the city of Chicago that provides long-term strategies to enable communities with technology.

3 Cowen, Tyler. Average is over: Powering America beyond the age of the great stagnation. Penguin, 2013.
Results

By synthesizing the pile of data that was gathered over a year-long research with the two Chicago-based initiatives, patterns started to emerge that were visibly in contrast with the mainstream startup culture that are following the Silicon Valley model of innovation. These patterns are currently organized under six categories of 1) Comfort, 2) Care, 3) Temporality, 4) Materiality, 5) Reappropriation, and 6) Empowerment. Each pattern is either aligned with or informative for the theories of alternative economy and innovation. The aspect which is specifically informing for design research is how these patterns could expand our understanding of infrastructuring. In a neoliberal society that the fast pace adoption of technology, looking ahead, and being efficient with time and resources are being promoted, these patterns are opening up an alternative look into how the innovation culture can be different, and the very different kind of infrastructures that are needed for promoting and replication:

- **Comfort**: In contrast to cool culture and fun environment of startups, here instead comfort is being embedded in every interaction. One tactic is by being transparent about the values that the initiative is beholding, for example their position in relation to LGBTQ communities, people with disabilities, and illegal immigrants creates a sense of comfort among members of those communities. Comfort is also traceable in their discussion sessions in which experts and city officials are treated equally and have the same say as first time participants.

- **Empowerment**: Although both initiatives are training knowledge workforce, but the empowerment is not in individual skills that they are learning, but through the new relations they are building. Individuals feel empowered by being around people who have the same vulnerability as they have, and their empowerment is in resistance.

- **Temporality**: These initiatives experience a very different relation to time. Unlike the quickening speed of technology that seem inevitable, these initiatives are sanctuary places for healing. Instead of looking ahead, it is encouraged to looking around and be mindful about the consequences of actions taken.

- **Care**: Unlike the obsession with change, care may not bring change. In fact, it is about intentional distractions in the flow of the process to see who needs attention and what needs maintenance.

- **Reappropriation**: Unlike the obsession with “new” and the next big disruption, one strong pattern that emerged is reappropriation, both in materials and content.

- **Materiality**: In order to engage the public and encourage them to reflect on socio-political dynamics, one strategy is to materialize the issues. In other words, provide a context in which participants can reflect on their everyday life and understand the higher level dynamics. The materialization, in contrast to abstraction of expert topics, encourages more diverse groups of people to engage in conversations and reflect on their aspirations for the future.
Discussion

In order to design a new narrative for the future of economy, this research looked at two initiatives that are already engaged in extraordinary social, cultural, and environmental entrepreneurial activities in Chicago, even though they are not generating revenue. This allows for analysis into how their values are translated into skills, motivations, and challenges, if not revenues. The data was used to drive insights which were then synthesized and translated into creation and introduction of a set of principles for design infrastructuring to promote an alternative mode of contributing to economy. These principles are 1) Comfort, 2) Care, 3) Temporality, 4) Materiality, 5) Reappropriation, and 6) Empowerment. The next step is to translate these principles into a set of engagement activities to rehearse participation in an alternative mode of economy. The goal of this phase is not to come up with a polished model, instead these engagements aim at bringing together wider range of audience together and facilitate a deeper reflection on their experience. From the insights extracted from those engagement sessions, a deeper understanding on translation of principles to infrastructuring strategies will be conceptualized. Finally, some frameworks translatable to various contexts will be developed, which will lead to guidelines for other designers.

Designing Physical Interventions to Improve Gestural Interactions with Science Simulations

Amanda Henderson, University of Illinois Urbana-Champaign, Champaign, IL, USA, akhende2@illinois.edu

Robb Lindgren, University of Illinois Urbana-Champaign, Champaign, IL, USA, robblind@illinois.edu

Abstract
This paper explores the collaborative process of designing a physical object to support a National Science Foundation funded educational research project. Researchers involved with this project are exploring the ways in which gesture can aid in a student’s ability to construct explanations of science phenomena, particularly ones that have unseen structures and unobservable mechanisms. In order to manipulate the science simulations, a motion sensitive device captures students’ hand gestures. It can be difficult for students to know how to engage with this device, which impedes both student learning and associated research. In order to reduce usability challenges and enhance the connection between a student’s gestures and the scientific concepts presented on the simulation screen, a collaborative and iterative design process was conducted to create a designed form that would assist students in productively engaging with the simulations. The iterative development process of this project is an exemplar of how designed items can be developed to support multidisciplinary research projects, while also creating new fields of research. Future exploration of this device’s impact on student interaction and learning may bring to light how objects can change how people gesture in learning contexts, leaving a lasting imprint on their understanding and memory.

Keywords: embodied learning, gesture, educational environments, affordances, human-centered design

Designers are frequently invited to participate in research projects after the study has begun. They are welcomed at a time when the research team has already developed the study, but may be displeased with the aesthetics of the experience. Difficulties collecting data from studies with poorly designed user experiences and interfaces is all too common; and ease of use is seen as correlated with a more “pleasant” appearance, as a result of the aesthetic-usability effect (Lidwell, Holden, & Butler, 2003). In many cases studies require the participant to interact with a screen-based user interface, but the participant’s experience of the study is so much greater than simply engaging with the researcher and screen; their entire environment factors into their learning experience. The participant’s perception of their environment influences the data collected as well as learning outcomes in the case of an educational research study. This paper discusses the impact of environmental influences on human perception and cognition; explored through the design development of one form, intended to benefit an embodied learning study.

Background
GRASP Project
The GRASP project (GestuRe Augmented Simulations for supporting exPlanations) is a National Science Foundation funded project focused on the impact gesture can have on learning. Gestures externalize and make visible a participant’s thought processes while learning new concepts, in addition to potentially increasing understanding and memory of the concept. For the GRASP project, these concepts focus on the scientific areas of thermal conduction, gas pressure, and the changing seasons. Each of these concepts can prove difficult for students to understand as the scientific phenomena themselves are unobservable by the naked eye (e.g., molecules colliding), and using gesture in explanations of these concepts has the potential to increase learning. Middle school students participating in the study interact with a variety of computer-based simulations of these three concepts, interacting with each through a gesture-tracking device called the LEAP motion. In order to engage each simulation the student must use specified gesture conventions within the use-zone of the device; participants are guided to use these gestures by the researcher running the study and the on-screen interface.

Two years into the study, the research team had made significant progress articulating the design considerations of the GRASP study as well as considerations for other studies run in gesture- augmented learning environments (Wallon & Lindgren, 2017). With these considerations in mind, the research team determined that bringing a designer onto the team would help enhance the student experience with the LEAP device and on-screen simulations; and amidst the process of implementing user experience adjustments, an opportunity arose to better the student experience through designed form.

Human-centered Design Process
In order to complete a human-centered design process, a designer must engage with the user experience from start to finish. Exploring all potential interactions and opportunities for user error, confusion, and misunderstanding. Empathic modeling, or placing oneself in the position of a unique user group, can be used to consider the experience from the view of the participant or researcher (McDonagh, Bruseberg & Haslam, 2002). Observation and interview are also essential in identifying and predicting user needs (Kelley & Littman, 2001).

In order to test the user experience of the GRASP simulations, it was important to engage firsthand with the experience of the study using only the simulation interfaces as a guide. Relying fully on the simulations and LEAP device for guidance, it was clear which steps in the user experience might be confusing to a new user without researcher instruction. As screen-based changes were identified and observation of researchers working with participants was completed, it became clear that participants were frequently experiencing difficulty understanding where their gestures should take place in the airspace over the LEAP motion device.

The LEAP motion is a small device that offers a low profile system for monitoring gestures, which in turn control computer simulations. While the size of the device is convenient for researchers to carry and setup, there was often interference in the study when student participants struggled to maintain a proper read out from the device. This issue would occur as students’ hands moved too high, too low, or out of the zone of readability for the LEAP motion. It became clear that participants could benefit from a physical intervention in their
environment. To address problems that students had using the tool, visual cues could be added to indicate the appropriate zone for interaction. This might allow students to offload extraneous thought processes as they participate in the embodied learning activity.

**Literature Review**

**Designing Intentional Environments**

Designing an intentional environment in which an embodied learning study will be run, relies heavily on how people perceive and react to elements within their surroundings. Humans experience the world through bodily positioning and senses; according to Johnson (1987), “our embodiment is essential to who we are, to what meaning is, and to our ability to draw rational inferences and to be creative” (p. xxxviii). The situated nature of embodied cognition makes a strong argument for studying the phenomenology of perceived material landscape in order to make more informed design decisions. Each designed form that exists within an environment adds to the material landscape. According to Barsalou (2008) the material landscape as a whole is perceived through the situated nature of all human experience and influences cognitive processes.

Considering a person’s surroundings as a pivotal factor in their cognitive processes provides essential information to the human-centered design research process, with the added potential of inspiring awareness of the need for a new product. As Roy Pea (1993) mentions in his paper on distributed intelligence, human cognition relies on perceived elements of environment in order to promote functional interaction. Pea (1993) states:

> …The environments in which humans live are thick with invented artifacts that are in constant use for structuring activity, for saving mental work, or for avoiding error, and they are adapted creatively almost without notice. These ubiquitous mediating structures that both organize and constrain activity include not only designed objects such as tools, control instruments, and symbolic representations like graphs, diagrams, text, plans, and pictures, but people in social relations, as well as features and landmarks in the physical environment (p.48).

Part of this understanding of the environment is based on schemas created over time; including place schemas that help people understand what sort of human activity should take place in an environment (Davis, 2002, p.80-82). As humans gain experience with varying environmental factors over time, they begin to have a better understanding of the affordances of various elements within a space. Affordances, defined by Gibson (1979), are the perceived potential interactions that people have with elements of their surrounding environment. This ability to “read” the functionality of a space provides an interesting opportunity to utilize implied affordances of a space and the physical interventions within it, in order to create an effective intentional environment. By studying perception of affordance, more informed design choices are able to be made in the creation of new forms and spaces where intentional gesture can be tied into the interaction. Building gesture into interaction with elements of the space may provide a more memorable and engaging experience, while also providing an additional way for a person to understand and explain a learned concept. As Susan Goldin-Meadow (2011) suggests, “gesture not only presages learning but also can play a role in
bringing learning about. Gesture can cause learning indirectly by influencing the learning environment or directly by influencing learners themselves. We can thus change our minds by moving our hands” (p.595).

In order to create environments that reduce cognitive load and encourage intuitive understanding or problem solving, epistemic action must be taken to build designer environments (Clark, 1998, p.511). By creating a built environment with areas structured to take on the weight of thought process, designers can reduce or eliminate cognitive stress points. Margaret Wilson (2002) elaborates on this potential in her third of six views of embodied cognition: people “offload cognitive work onto the environment. Because of limits on our information-processing abilities (e.g., limits on attention and working memory)... we make the environment hold or even manipulate information for us” (p.626). The implications of people using their environment to hold and manipulate information, provides another interesting opportunity for designed interaction. People may be able to use designed forms in the environment to eliminate cognitive stress points, improve learning and memory, and change their understanding of information; which in turn might change their perception of the world around them.

Further considerations regarding the design of the GRASP study can be found in Wallon & Lindgren (2017).

**Research Methods**

While in the process of improving the aesthetic and user experience of the GRASP simulations, it became clear that there could be an improved interaction with the LEAP motion device through some type of physical intervention that might make the user’s gestural experience more intuitive. This designed form’s intention is to help study participants understand where their gestures need to take place in relationship to the LEAP device that is tracking their motion, while not interfering with their view of the science simulation they are controlling. Considerations at the start of the design process included the nature of embodied learning, situated cognition, perceived affordances and the potential for cognitive offloading.

Through a collaborative, iterative human-centered design process a hand guide device was developed. This hand guide device was designed in correspondence with the GRASP researchers as they made advancements to the current study; the goal of designing this device was to customize the learning experience of the GRASP study, and help prepare for future iterations of the study.

**Observation and Inspiration**

Initial experience and observations of interacting with the GRASP simulations and LEAP motion device indicated that there is an optimal functionality zone for the LEAP motion device to properly control the simulations (figure 1). It also became clear that this device would have two very different user interactions. For participants in the study, this device would act as a hand guide that they did not come in contact with, but used as a visual reference to inform their gesture locations. Additionally, based on the function of the LEAP device, students had access to a feedback loop from the simulations, as their gestures either succeeded or failed to control the simulations while referencing the hand guide (Lidwell et. al., 2003, p.
Researchers, on the other hand, would be physically interacting with the device: carrying it, setting it up, making adjustments, and referencing it throughout the study.

The researchers’ needs inspired some of the key features of the device: basic size, need for modularity, adjustability, and identifiable features. The study participant’s interactions with the device, in addition to the content of the science simulations (unseen structures eg. molecules), lead to an exploration of ephemeral imagery (e.g., light, particles, ripples in water, natural forms) as well as aboriginal dot paintings; artworks created as a symbolic representation in the process of telling tribal stories, similar to the way gesture can be a physical representation associated with the explanation of a concept.

Figure 1: the LEAP Motion device has a specific gesture zone for optimal performance.

Early Sketches and Low Fidelity Prototyping
Early sketches of the hand guide focus on the device’s goal of helping study participants visualize the gesture zone where the LEAP device will pick up their motions. This affordance is implied through the use of lines, taking into consideration the gestalt principles of perception: closure and good visual continuation (Ellis, 1999). The device also begins to act as a symbolic barrier between the study participant and the computer screen, with the figure ground relationship of the space contained by the hand guide as the apparent interaction zone (Vecera, Vogel & Woodman, 2002).

Of the initial sketched concepts, one enclosed hand guide and one open format hand guide were chosen by the GRASP research team to be prototyped (figure 3). These prototypes allowed for testing with the LEAP device and simulations. The enclosed hand guide caused some issues with the function of the LEAP device as well as obstructing some views of the simulations. The open format concept can be adjusted for various gesture widths, depending on whether the gesture requires one or two hands in motion.
Figure 2: Initial concept sketches (front view) of the hand guide device. These sketches fall into two categories: enclosed hand guides and open format hand guides.

Figure 3: Initial, low fidelity prototypes of an enclosed hand guide and an open format hand guide.
User Testing
GRASP study participants who had the opportunity to engage with the two hand guide devices greatly preferred the open format hand guide (figure 4). One student stated, “I feel like [the open format hand guide] is more useful, because it’s a show of where you’re supposed to put your hands. Yeah, cause it shows exactly where you’re supposed to put your hands for it to operate most efficiently.” While the researchers reported that the students engaging with the open format device had successful interactions with the simulation. These reactions may indicate that the device offers an expectation effect, improving overall performance based on the expectation of better performance (Lidwell et. al., 2003, p. 68-69). The implementation of the hand guide device could increase a study participant’s confidence engaging with the simulations, leading to an improved outcome.

![Figure 4: Students working in a dyad interact with the enclosed and open format hand guides. Participants that interacted with the low fidelity models provided feedback on their experience interacting with each hand guide.](image)

Design Iterations and Functionality
After testing with the low fidelity prototypes, it was determined that the design would move forward with the open format hand guide system. A number of design iterations were explored for these guides (figure 5); experimenting with various identifiable features used to visually cue participants, but the research team determined that the initial designed form for the hand guides was preferred as it drew inspiration most directly from the molecules depicted in the simulations. The researchers also identified that the device needs to be very easy to set up, tear down, and transport to and from schools. This feedback guided the design process towards a modular carrying system. Multiple conceptual directions were explored to create a device base that functions as both the support for the adjustable hand guides and a carrying case (figure 6).
Figure 5: Multiple iterations of the open format hand guide were created. The research team and participants ultimately chose the initial form concept from the available iterations.

Figure 6: Functionality brainstorming and testing was completed prior to the assembly of the final model.
Findings

The current developed model (figure 7) is constructed out of laser cut acrylic, plywood, magnets, and fasteners. The device can be carried with the detachable hand guides magnetically fastened to the side. When in use, the hand guide pieces magnetically attach to two sleds that can be moved left and right to accommodate for gesture width. The based of the device also features an area for the LEAP motion to rest securely throughout testing.

![Figure 7: The current hand guide device that is being used for the GRASP study.](image)

Discussion

Researchers have begun use of the current iteration of the hand guide device (figure 8). As the researchers include the hand guide device in their explanation of the science simulation, study set up, and gestural interactions the device has the potential to act as a tool for cognitive offloading. The device gives participants a reference within their visual field of where the researcher indicated that they should complete their gestures throughout their interaction with the simulation. In early use, researchers reported that even having the hand guide device in the room to point at seemed to be advantageous. Further testing needs to be completed to document the impacts of its use and continue shaping further design iterations of this device.

Additional takeaways from initial tests with this model include: the need to reduce the weight of the overall device (primarily caused by the plywood base), eliminate the use of exposed hardware, and create magnetic sleds out of a single material for long term durability. The potential for unique hand guide sets for each simulation is also in consideration. The current design is specifically for the GRASP research project, but could support eventual
development for all Leap motion devices.

Figure 8: GRASP researchers using the hand guide device for individual student interviews.

The GRASP research project is ongoing, and the hand guide device has been incorporated into recent and upcoming data collection. As the project moves forward, the research team will continue to complete dyad interviews, utilizing a single computer and leap device, while also beginning to explore applications within a larger classroom context. This shift may lean towards the use of individual tablets for students or could involve augmented reality technology (e.g., Microsoft hololens). The design of future studies will take into account the impact of the hand guide developed throughout the course of this project and potentially incorporate a similar visual cue as part of the simulation interface or augmented reality experience.

Conclusion

The development of this hand guide device provides an example of opportunities that arise from focusing on the design forms and human experience of intentional learning environments, taking into consideration the situated nature of embodied learning. The GRASP research team identified the benefit of taking all aspects of the learning environment into consideration and took action to further diversify the expertise of their team. Each designed form in a material landscape has an impact on the human experience and has the potential to play a crucial role in learning in an educational setting. The initial outcomes of this project bring to light some interesting research questions pertaining to the influence of designed form on gesture, learning, and memory in an educational setting. These emerging questions and research areas act as a reminder of the importance of interdisciplinary engagement, inspiring future collaboration and exploration in order achieve better design outcomes.

**Author Biography**

Amanda Henderson

Amanda Henderson is a design researcher with a background in industrial, scenic, and exhibit design. After completing her undergraduate degree in Industrial Design at Carnegie Mellon University, with a minor in Photography, she spent five years in the exhibit design industry. This experience inspired a curiosity to pursue her research focus: how designed forms change human perception of a spatial environment; with the ultimate goal of creating spaces that allow people to feel comfortable and knowledgeable interacting with their surroundings. She is currently pursuing her MFA in Industrial Design at the University of Illinois (Urbana-Champaign); where she is an Instructor of Record at the School of Art & Design and Designer in Residence at the Beckman Institute for Advanced Science and Technology.

Robb Lindgren

Robb Lindgren is a learning scientist and educational technology designer in the College of Education at the University of Illinois at Urbana-Champaign. He is currently an Associate Professor in Curriculum & Instruction and Educational Psychology. His research examines theories and designs for learning within emerging media platforms (e.g., simulations, virtual environments, mobile devices, video games, augmented and mixed reality, etc.). He seeks to understand how digital technologies can be used to construct new identities and generate new perspectives that lead to stronger comprehension of complex ideas, particularly in STEM content areas. His work investigates how physical, body-based interactions with learning content can facilitate new understandings, and how games and simulations can be effectively designed to take these types of interactions as input.
"Fast" and "Slow" Fashions as seen through the Millennial Mindset

Hernández, Abel MFA Candidate, Design Research and Development, The Ohio State University Columbus, Ohio, USA hernandez.390@osu.edu

Abstract

The term “slow fashion” was coined by Kate Fletcher to counter the growing trend of the “fast fashion” industry. In recent years, the clothing industry has been dominated by fast fashion that has spurred overconsumption whereby people buy more than they need.

This study aims to develop a critical-creative thinking framework based on the understandings and insights of how Millennials view apparel consumption. Lynda Grose and Kate Fletcher’s chapter “Transforming Fashion Product” from their book Fashion & Sustainability: Design for Change (2012) provided useful information regarding the fashion process, helping to reveal new patterns to frame how participants of this study view apparel consumption. This research investigated the way in which consumers viewed material, consumer care, and disposal of their clothing.

In order to understand the Millennial mindset with regard to apparel consumption, responses were collected from over a hundred Millennials through an online survey (Phase One), where they discussed their reasons for placing themselves along a scale from slow to fast fashion. The findings uncovered a new group of consumers, the undecided+exploring, who identified with both slow and fast fashion. Valuable insights extracted from the survey informed the development of a research toolkit for a series of participatory workshops (Phase Two) with the goal to construct a conceptual model of Millennial apparel consumption.

Further understanding of slow fashion, as seen through the Millennial mindset, will inspire and guide designers, manufacturers, and consumers to make more sustainable decision when developing, selling, and buying clothing items.

Keywords: Slow Fashion, Fast Fashion, Sustainability, Millennial Generation, Apparel Industry

With a population of 80 million, the Millennial population, born as early as 1977 (Fromm & Garton, 2013) and as late as 2004 (Horovitz, 2012), is one of the leading forces in consumer spending in the United States (Fromm & Gardon, 2013). Millennials are one of the largest populations to shop at fast fashion brick and mortar retail stores including Zara, H&M, and Topshop (Kestenbaum, 2017), and online at sites like Amazon.com and Nordstrom where sales have increased (Rey, 2017). Millennials spend $600 billion on clothes each year, but their rationale and decision-making processes are rarely studied or understood (Kestenbaum, 2017). While innovation in clothing production speed in the fast-fashion sector has decreased the price of clothing and made it accessible to most of the population, it has also created a throw away
economy where inexpensive clothing products can be easily discarded (Pookulangara & Shephard, 2013).

In recent years, the slow fashion movement has taken shape across the world (Blair, 2015). With internet access and social media, Millennials are becoming more aware of fast fashion’s wasteful supply chain (Mak, 2016). Slow fashion is not completely the opposite of the fast fashion movement. They both deal with the fashion cycles but slow fashion focuses more on longevity (Fletcher, 2008, p. 175). Slow fashion has become prevalent amongst fashion industry leaders and researchers alike because it encourages a clear understanding of the materials, labor, care, and repurposing of clothing items (Fletcher & Grose, 2012). Instead of a just-in-time production process (Pookulangara & Shephard, 2013), slow fashion encourages consumers to hold on to clothing items longer and repair their clothing items when need be.

With the growth of both the fast and slow fashion industries, there is a group of Millennials who do not identify with only one fashion style, these consumers are called the undecided+exploring. This group of consumers exist between fast and slow fashion as they share attributes of both fashion styles. These Millennials grew up buying fast fashion products that were inexpensive and plentiful (Mak, 2016), and still do. Yet, they are aware of more sustainable, slower approaches to fashion and the value of higher quality items versus cheap clothing bought at major fast retailers. They choose to explore by adjusting their style; mixing and matching clothing items by combining slower, higher quality items like jackets, jeans, and shoes with faster ones like t-shirts, swimwear, and socks.

**Literature Review**

**Transforming Fashion Product**

Lynda Grose and Kate Fletcher’s (2012) book *Fashion & Sustainability: Design for Change* was used to develop a framework upon which to base the current and ideal clothing journeys of apparel to be used in participatory workshops with Millennials. Fletcher and Grose stress the importance of looking at aspects of the cycle of clothing production and consumption in order to positively affect change towards a more sustainable future reflecting a way of thinking which sees each part of the fashion industry’s products, systems, and practice as a whole fashion cycle that has to undergo improvement and not just a few isolated parts (2012, p. 11). They pose a critical question: “Are there principles and metrics we can agree upon that are key to a world that is not only sustained, but also actually restored? Second, with these shared principles, can we create a framework for change that guides business activities in the fashion industry, a framework that is practical, scientific, and economic?” (Fletcher & Grose, 2012, p. 4). Fletcher and Grose have used their Transforming Fashion Product concepts (Materials, Processes, Distribution, Consumer Care, Disposal) to explore “opportunities for improving fashion products” (2012, p.11). This research focused on the examinations of how Millennials buy, use, and discard clothing. Participants were not particularly or directly asked in the survey portion to discuss their knowledge of clothing products construction or distribution.

**Deep Metaphors**

This study (Phase Two: participatory workshops) utilized Gerald and Lindsay Zaltman’s
metaphors from their book *Marketing Metaphoria: What Deep Metaphors Reveal about the Minds of Consumers* (2008) as a viewing lens to reveal Millennials’ rational and emotional states of mind on fast and slow fashions. Deep Metaphors as described by the Zaltmans are “enduring ways of perceiving things, making sense of what we encounter, and guiding our subsequent actions” (Zaltman & Zaltman, 2008, p. xv). The seven deep metaphors are: 1) balance, “how justice, equilibrium, and the interplay of elements affect consumer thinking”; 2) connection, “how the need to relate to oneself and others affects consumer thinking”; 3) container, “how inclusion, exclusion, and other boundaries affect consumer thinking”; 4) control, “how the sense of mastery, vulnerability, and well-being affects consumer thinking”; 5) journey “how the meeting of past, present, and future affect consumer thinking”, 6) resource, “how acquisitions and their consequences affect consumer thinking”, and 7) transformation, “how changes in substance and circumstances affect consumer thinking” (Zaltman & Zaltman, 2008, p. x). While the context of the Zaltmans’ Deep Metaphors were geared towards marketing, the seven universals metaphors was used in this research to better understand the thinking of Millennials’ with regard to fast and slow fashions.

**Research Methods**

The research utilized both quantitative and qualitative research methods (Sandelowski, 2011). The quantitative data were collected from online surveys of over 100 respondents from all generational groups including Boomers, Gen-z, and Millennials. Gathering data from all generational groups was done for the purpose of examining the differences between Millennial consumption habits and those of other generational groups. The qualitative data were collected via participatory workshops.

**Phase One: Survey**

The survey invitation was sent out online, with an emphasis on identifying participants that are part of the Millennial generation. The format of the survey consisted of closed, open, and dichotomous questions, as well a slider scale (Law, n.d.) that was used to understand where participants viewed themselves in terms of fast or slow fashion data.

Participants were asked about their clothes shopping and washing habits. Questions included: What’s the average amount you spend on clothing items? Where do you currently buy most of your clothes? How often do you shop for new clothes? How often do you wash your clothes? What do you do with your old clothes when you’re done using them? A slider scale was used to see where participants perceived themselves to be on a scale from one – signifying slow fashion to five –signifying fast fashion. Participants were then asked to write down three attributes (short phrases) that described their perceived position (i.e., where they positioned themselves in the scope of fast and slow fashion).

The open-ended questions asked participants, based on their positioning from the slider scale question, to provide a brief statement describing why they placed themselves where they did. The data from the survey helped identify patterns amongst the different Millennial apparel consumers. The survey was also utilized as a recruitment tool for Millennials who would be willing to participate in the second phase of the ongoing research, the participatory workshops.
Discussion

This research looked to identify the decision-making habits of Millennial clothing shoppers who identify as either fast or slow fashion consumer to develop a critical-creative thinking framework based on the understandings and insights of how they view apparel consumption.

The preliminary findings of this study were analyzed from primary and secondary data, scans of popular culture, and publications related to fast and slow fashion. The preliminary analysis of the data showed similar patterns of consumption tendencies and rationale for purchasing clothing items relative to past studies, particularly Watson & Yan’s *An Exploratory Study of The Decision Processes of Fast Versus Slow Fashion Consumers* (2013). Watson & Yan found similar patterns in fast fashion consumers that seek out trendy and lower quality clothing items, which leads the consumer to dispose of or donate their clothing item at higher rate. They also state that slow fashion consumers generally hold on to their clothing items longer because their shopping tendencies are not based on trends, but rather quality (p. 149).

The following section looks at ways in which Millennials view material, consumer care, and the disposal of their clothes. Please note: test of statistical significance between group differences are underway now and are not reported in this paper. When looking at materials, fast fashion consumers were willing to compromise quality to get a lower price, while slow consumers were the opposite. Slow fashion consumers were willing to spend more in order to buy clothes they felt would last longer and didn’t represent a “trendy” style. They also wanted “timeless” articles of clothing of higher quality, while younger fast fashion consumers would rather buy cheaper clothes they don’t expect to last a long period of time.

In terms of consumer care, fewer fast fashion consumers had their clothes repaired or altered by a tailor than did slow fashion consumer: the percentage of fast fashion consumers was 28% and slow fashion was 39.6%. Altering clothes to fit better can encourage Millennials to hold on to them longer, while repairing them can keep articles of clothing out of the landfill. However, only 25% of the undecided+exploring consumers would repair or alter their clothes.

![Figure 1: The frequency of washes for fast, undecided+exploring, and slow fashion Millennials](image-url)
The number of wash cycles an item of clothing is put through in its life cycle greatly compromises the integrity of the fabric, breaking down the fibers, and accounting for most of the carbon footprint of clothing (Levi’s, 2015). When it came to washing their clothes, 61.9% of fast fashion consumers washed their clothes once a week, slow fashion consumers 41.2%, and undecided+exploring consumers washed theirs 20%. Slow fashion consumers had a highest percentage of monthly washes (19.6%) than fast fashion (14.3%), and undecided+exploring (10%) consumers (Figure 1).

When it comes to disposal, Millennials that identify as fast fashion consumers differ from the other two groups of Millennials. Fast fashion Millennials mentioned throwing their clothes away (3.4%), while slow fashion Millennials didn’t even select it as an answer (0%). Though, fast fashion Millennials were more likely to donate their clothes (79.3%) than slow fashion Millennials (66.7%), but slow fashion Millennials nearly doubled the fast fashion Millennials in terms of selling their clothes at consignment (26.7 % vs 13.8%).

The findings from this study identified that most fast fashion consumers appear to be mostly male (51.2%), while women accounted for 46.3%, and people associated as gender fluid or gender queer made up 2.4 %. These fast fashion Millennials often shop for clothing items while keeping their expenditure low. They value the ability to buy inexpensive clothing items, especially since they do not seem to be concerned with owning an article of clothing for a very long time. This group doesn’t necessarily feel guilty for their overconsumption of inexpensive clothing items because they are more interested in following trends than dressing in a timeless manner. The practice of over laundering is more prevalent amongst these Millennials, therefore increasing their carbon footprint by consuming more natural resources such as water and energy (Levi’s, 2015).

Unlike fast fashion consumers, undecided+exploring Millennials are playing both sides of the field so to speak. This group consists of Millennials in the middle of their age group, 90% are 30 years and younger. They occasionally dabble at buying cheap clothing items from fast-fashion stores but tend to hold on to the clothes for longer periods of time. They are aware slow fashion brands that emphasize product quality and longevity, but they either can’t afford these slow fashion brands or they are more interested in the satisfaction of having trendy and in style. They occasional repair or alter their clothing items and are more likely to buy from consignments stores. These undecided+exploring consumers are both attracted to cheap fast fashion and also invested in slow fashion clothing that lasts longer.
Slow fashion consumers tend to be older Millennials who spend more money on their clothing. 11.8% of this group of Millennials said they would hold on to their clothing items for 5 to 10 years while only 4.8% of fast fashion Millennials would for this amount of time. 10% of the undecided+exploring consumers said they would keep their clothing items for over 10 years (Figure 2). Slow fashion Millennials not only value quality over style, they are willing to pay more for it. Participant #1 wrote, “As I have gotten older, quality clothes are more important to me because it is my hard-earned money and I do not want to buy clothes or shoes again in a month.” In the survey, there were no Millennials who identified themselves as fast fashion consumers that spent more than $200 on a clothing item.

**Conclusion**

To conclude, this research is looking at the ways in which Millennials buy and care for their clothing items and whether they identified as fast or slow fashions consumers. Elements of Fletcher & Grose’s “Transforming Fashion Products” concepts (2012) provide this study with a conceptual framework for understanding the current fashion cycle, from materials, processes, distribution, consumer care, to disposal. Although this research specifically studied slow and fast fashion consumers, a third category of fashion consumer, the undecided+exploring, emerged from the findings. This consumer type is not considered either fast or slow, but rather a group that resides in between the two. They are aware of fast and slow fashions and can decide what avenue to go down. These undecided+exploring consumers are going through physical and economic transformations as they mature.

The preliminary findings from the research revealed characteristics of fast, undecided+exploring, and slow fashion consumers, presenting slow fashion Millennials as more interested in higher quality, long-lasting clothing items and not obsessing over trends. Both donated all their old clothes, while 4.8% of fast fashion consumers stated that they occasionally throw clothes away. The fast fashion consumers were more interested in temporary fashion that does not have to stand the test of time.

As more fast fashion consumers become aware of slow fashion as it grows in popularity, they
will likely go through the undecided+exploring state. As they start to transition to a slower state, they can start to look for higher quality new or used clothing items while minimizing their energy and water consumption when caring for their clothes. More research and data collection can help to understand the transitional state of fast and undecided+exploring Millennials.

Valuable insights extracted from the survey informed the development of a research toolkit for a series of participatory workshops (Phase Two) with the goal of constructing a conceptual model for the final analysis. The findings will support the development of a critical-creative framework that will inspire and guide designers, manufacturers, and consumers to make more sustainable decision when developing, selling, and buying clothing items.

**Next Steps**

The Phase Two research process for this study is still in progress. Three participatory workshops have been conducted and two additional sessions are scheduled for completion in a few weeks. The following descriptions present the research toolkit, process, and preliminary outcomes from the first two workshops.

The first exercise (Figure 3) consisted of a preliminary positioning, where participants were asked to mark on a line where they currently see themselves in terms of fast or slow fashion. Each participant was asked to mark their perceived location on a sheet that read FAST on the left side and SLOW on the right side with a line connecting the two ends.

![Preliminary Positioning Exercise](image)

Figure 3: Preliminary Positioning Exercise, visual summary of preliminary workshop data

Then the participants were asked to work together on creating a current journey map (Figure 4) for a clothing item utilizing the Transforming Fashion Product concept (Fletcher & Grose, 2012). The five steps listed in the journey consist of: Materials, Processes, Distribution, Consumer Care, and Disposal. Fletcher & Grose state that in order for change to be possible and to find solutions, people must understand the current process and what it can be. The participants used toolkits consisting of visual materials that were provided to them to help them be able to communicate and reveal their thoughts and perceptions.
Gerald and Lindsay Zaltman’s “Deep Metaphors” was used as a viewing lens to reveal Millennials’ rational and emotional states of mind on sustainable fashion. The seven Deep Metaphors—Balance, Transformation, Journey, Container, Connection, Resource, and Control— are universal drivers of human behavior that shape what people think, hear, say, and do (Zaltman & Zaltman, 2008). Participants were presented with the seven metaphors and a brief description of each on seven posters. They were asked to fill the posters (Figure 5) with visual and written statements regarding fast or slow fashion. The toolkit included visual materials to help participants to express what they were thinking and feeling, they worked simultaneously on different metaphors.

After discussing their shopping habits, the Millennials focused on the clothing journey of
apparel. They were asked to envision the ideal journey (Figure 6) of a future clothing product utilizing Fletcher and Grose’s Transforming Fashion Product concepts. This second mapping exercise allowed the participants to take their shared knowledge and collaborate on a more sustainable and transparent journey map for a clothing product.

![Figure 6: The Ideal Journey of a Clothing Item, visual summary of preliminary workshop data](image)

To conclude the participatory workshops, participants were asked to again mark on the line where they saw themselves at the end of the session (Figure 7). This was used to document any changes in perception from the beginning of the session to the end.

![Figure 7: Post-Positioning Exercise, visual summary of preliminary workshop data](image)

The author will summarize various aspects of fast and slow fashions mindsets through the viewing lens of selected Deep Metaphors with collages made up of photographs, illustrations, narratives, quotes, visual and written definitions. The final outcomes of this study could be applied to identify new mindsets for educating and inspiring responsible approaches in the apparel industry by encouraging people embrace slow and sustainable fashions.

**Author Biography**

Abel Hernández

Hernández’s Master’s thesis research investigates the subconscious and deeper understanding behind the decision-making process Millennials go through when purchasing, using, caring, and discarding their clothing products. He is particularly interested in “slow fashion”, a term coined by Kate Fletcher in 2007, that counters the growing trend of the “fast fashion” industry. In recent years, the clothing industry has been dominated by fast-fashion that has spurred overconsumption where people buy more than they need, which has created a throwaway mentality. The aim of his research is to develop a critical-creative thinking framework based on the understandings and insights of how Millennials view apparel consumption.
Look Around You, Look Inside You: Exploring Heritage in the Design Classroom

Maria Gabriela Hernández, University of Florida, Gainesville, FL, ghernandez@arts.ufl.edu

Abstract

How can students at a federally-designated Hispanic-serving institution understand and express culture and diversity through art and design? In order to address this inquiry and to exemplify a method that introduces students to critical thinking in the context of design, I am presenting a case study based on the primary results of a project implemented at an introductory graphic design class, which is part of a multidisciplinary arts program. In this project, students learn basics of design research and auto-ethnography in a studio setting, in order to explore heritage and culture, their context of living, family history, and personal connections with their past, present, and future. Results from this discovery stage inform brainstorming, sketching, design, and production of a book that contains multiple visual explorations on “Heritage.” Some of the most memorable and productive conversations and interactions between students took place not only during the development of the project, but at the final project presentation, which exposed their capacity to develop greater tolerance and a more empathic view of the other, to be open to reanalyze their context and personal interactions, to better evaluate the design abilities of their peers as they respond to their own individual approach to the topic, and to develop a better and safer sense of place in the classroom.

Keywords: Design Research, Design Pedagogy, Cultural Identity, Heritage, Empathy, Design Philosophy

Design education in the United States continues to be highly Eurocentric. From the glorification of Gutenberg’s letterpress invention to the systemic praise to the Bauhaus, design students are largely exposed to design history, knowledge and practice that builds on a historically Western, “first world” take on design, where there is very little space for exploration and discovery of the role of design in the development of other global cultures and societies through time. Such learning gaps tend to exclude students from experiencing the influence and impact of design and art in social development and cultural identity in a practical way.

Aiming to explore alternative non-colonialist design teaching methods that seek to correct this dominant representation of the history of design (Adamson, Riello, & Teasley, 2011), in 2016 I developed a project for an Introduction to Graphic Design course that is part of a multidisciplinary arts program (Bachelor of Arts in Fine Arts) at the University of Houston-Downtown (UHD). A Federally designated Hispanic-serving university, UHD had a Hispanic and/or Latino student representation of 48.6% in 2016. In the same year, 22.1% of students enrolled were African American, and 15.8% were White/Caucasian. Asian or Pacific Islander students represented 9.8% of the population (Office of Institutional Research, 2017). This diverse population (much of which has experienced immigration in their lifetime, as well as significant cultural separation from their home countries or their parents’ culture) has limited
opportunities to reconnect or even rediscover their heritage as higher education students. As Juliana Jones points out, to a great extent these students are “shaped by their cultural environment,” the place they now live in, internalizing cultural values (Jones, 2011) that may not exactly be the ones they originally identified with or come from. Many of these students struggle with finding their own place in society and the higher education system as immigrants or children of immigrants in an environment that is dual and many times conflicting, where family and community traditions, language and culture confront the pressure to acquire, adapt and prevail in the American society and economy.

The project, called “40 Ways to Visualize Heritage,” was created to facilitate design learning with a focus on cultural identity and heritage while supporting students with developing a sense of place, self-worth, and understanding of the other. In this paper I present methods and findings from the application of this project during two long semesters in a class composed by freshmen/sophomores, many of whom have never been exposed to exploratory visual methods. The discussion in the following pages includes the benefits of activating design learning methods to support the democratization of heritage engagement (Purkis, 2017) through the implementation of introductory design research activities employing artistic exploration.

**Framework and Theoretical Base**

The class project was first introduced through a series of lectures using simple concepts related to culture, heritage and identity. The Center for Heritage and Society of the University of Massachusetts Amherst offers a very comprehensive definition of heritage, explained as “the full range of our inherited traditions, monuments, objects, and culture. Most important, it is the range of contemporary activities, meanings, and behaviors that we draw from them.” (Center for Heritage and Society, University of Massachusetts Amherst, n.d.). Students in the class were given this and similar definitions and were then invited to discuss what heritage means for them and those around. With the intention to jumpstart critical thinking and to continue building a more tolerant class environment, students shared short oral stories about their geographic origin, cultural identity, and/or family traditions with an approach that supports open-mindedness and self-empathy with their own background (i.e., at first, many students tended to minimize the relevance of their own heritage or culture compared to others’—several White American students, for example, showed lack of interest in exploring their origin because they believed their “whiteness” *is not interesting enough*), in order to identify similarities and differences within their group. Since the beginning of the project, students are asked to identify and reflect on social preconceptions and implicit bias during class discussions, which may limit in-depth exploration of conceptual, artistic, and inclusive ways to express heritage holistically.

In general, these introductory theoretical exercises are based on oral discussions that also resulted in the identification of keywords and central topics that influence the project for the class as a whole. At first, students discover a general tendency to reason their and others’ heritage and cultural backgrounds in a rather stereotypical fashion, showing the imposition of colonized interpretations and representations of indigenous and non-western cultures which have helped construct narratives of cultural reality (Rogal, 2016). A mental shift towards a
deeper understanding of heritage through the progressive discovery of cultural meanings and interpretations allowed them to de-center their worldview “in order to better comprehend different value systems” (Rogal, 2016) even within cultures that they have identified with during their lifetime. This kind of auto-ethnographic research also includes the study of signs and symbols within communities and family/social circles, which in a demographically diverse classroom resulted in a more insightful and inclusive discovery of cross-cultural communication (Jones, 2011), including language differences and similarities and local, national, and global traditions, and how they influence the way we share and develop multicultural relationships.

The class project had a strong art and design focus. Principles of graphic design methods were introduced for several weeks prior and during the implementation of the project, in order to enable students to understand and further visualize their cultural research. All students in the class were given a shared framework where visual thinking (Lupton & Phillips, 2015) was emphasized to facilitate the organization and categorization of research about heritage that could be visually expressed in small parts, each of which addresses a specific design concept.

**Project Methods**

The “40 Ways to Visualize Heritage” project considers one specific mode of design research: *Research Through Design* (Laurel, 2003), focusing on the use of methodologies to address a problem, provoke inquiry and propose solutions through the development of a project. In many ways, *Research Through Design* is not about what is being designed after all, but rather the knowledge it is being produced from the process (Storni, 2015). It informs the development of design from the beginning, resulting in more honest communication separated from persuasion (Laurel, 2003). This approach supported the facilitation of a creative and tolerant environment where students were able to employ art and design principles to identify and research their heritage, discover what it means within their own cultural context, and explore iterative visualizations, in order to produce a series of mini-case studies that would open spaces to leverage empathy and further discuss issues on culture, diversity, and inclusion.

During the project’s introductory stages, mind maps visualizing preconceptions of heritage were used to spark students’ inquiry, followed by discussions on cultural stereotyping (Figure 1). This led to three weeks of discovery complemented by short exercises of experimental artistic creation, such as the development of “cultural” color palettes—reflecting on the use of color within their culture, inspired by foods, fabrics, flags, traditional dresses, and nature—and production/reproduction of textures from rubbing over surfaces (weavings, rough materials, carvings, furniture) or by using multimedia and collaging employing cultural ephemera, storybooks, magazine clippings, newspapers, food wraps, festive supplies (*papel picado*, used traditionally as decoration for Mexican celebrations was a specially popular material among students exploring their Mexican, Aztec or Maya heritage), spices or dry leaves (Figure 2).
Auto-ethnography and observation, as well as 1-on-1 interviews were the most relevant methods students used to investigate their own cultural context (Figure 2). Their first research subjects were themselves; then, their families, social circles, and familial historic documents. Students were asked to also keep a visual and written journal to collect reflections on every tradition they are part of that represents their cultural heritage and identity and to investigate their origin.

During class conversations on these methods, students expressed their findings by orally describing the intricacies of dishes that characterize their cultural identity (a student expressed a mix of surprise and pride after discovering that her husbands’ Australian nationality has progressively changed her Irish/Polish culture gastronomically—*I now enjoy baking Pavlova*...
more than cakes!), the continuity of traditional dances in their family festivities (a student of Cuban descent: learning to salsa dance is a rite of passage for our family), the meaning of traditional dresses, patterns, language, and symbols that perpetuate cultural unity, the relevance of traveling to countries considered the origin of their cultural heritage and their family’s identity (various students with Mexican parents: every year/time I visit Mexico I feel I’m going back to my roots), and the benefits or conflicts that arise from living in the United States while maintaining a multicultural background. One Colombian-American student in particular shared a testimony that led to a class discussion on social pressure and discrimination in the context of cultural heritage:

I was born in the United States—I never learned Spanish well, although I was raised in a predominantly Hispanic neighborhood. Especially during my teenage years, my friends would make fun of me because of my broken Spanish. I grew up being bullied because I wasn’t Colombian enough.

Written testimonies using hand-drawn lettering was one design technique some students used to reflect findings and observations from their journals and after participating in oral discussions.

For the duration of the project (six weeks) students produced forty 3x3-inch visual interpretations of their cultural research using the following design/art principles: color theory, grouping, visual hierarchy, emphasis, framing and containment, figure/ground relationships, texture, pattern/repetition, balance, transparency, contrast, and continuity. At the end of the six weeks, students would participate in a final critique session where all forty solutions were shared with the class (composed by 15-20 students) in a book format (Figure 3). Each student was given time to review all their classmates’ books (an activity that took approximately 30 minutes), leading to a class discussion on how the production of these 40-solution books changed their perspective of heritage, the other, and their own cultural identity, as well as their position on design as a tool for cultural empowerment.

Figure 3: Two “40 Ways to Visualize Heritage” project samples. Individual designs, closed, and open flag books. On top, the project belongs to a student who visualized her Polish-Irish-Australian-San Franciscan heritage. On the bottom, the project visualizes a student’s heritage of Oaxacan/Mexican-American background.
Preliminary Conclusions and Further Steps

The facilitation of opportunities for sustainable, culturally-sensitive, and inclusive creative activities in institutions of higher education that serve multi-ethnic and culturally diverse students is relevant to guarantee safe learning spaces and to generate an equitable sense of place. Students of international origin or from multicultural backgrounds are a source of inspiration not only for their own peers, but also for academics. My former undergraduate students from the University of Houston-Downtown exposed points of view and experiences in class that helped me expand the reach of design teaching and design knowledge into a more pragmatic and context-aware sphere, where the opportunities to explore the resolution of real-world problems with social, economic, or developmental impact prevail while facilitating tolerance and better class dynamics.

Students who participated in the “40 Ways to Visualize Heritage” project demonstrated a deeper understanding of heritage and cultural identity after its completion. As the project progressed and they participated in more lectures, discussions, visualization exercises, and critiques, students gained stronger reasoning of their own world vision, discovering that it is based on different beliefs, interpretations of forms and practices of everyday life that underpin culture, their provided explanations of origin, as well as understanding of their own “self” (Fry, 2017). Many students belonging to first and second-generation immigrant families, for example, exposed an issue that it is not sufficiently explored or visualized within design teaching and practice: journeys from the third to the first world, and the difficulties to replace one way of life with a new one (Alden, 2011). By producing their 40-solution book, they visually unveiled mental, cultural, and social transitions, as well as physical, social and economic changes that occur during and after geographic mobilization, often resulting in the disintegration of cultural traditions (Alden, 2011). For many of these students, being able to unearth and revive their culture was an empowering way to show pride and reveal their identity, allowing their peers to familiarize with non-stereotypical expressions of culture.

Reflecting on the project’s further exploration, I discovered theoretical weaknesses in topics such as design for/with the global south; the relevance of diasporas to inform culturally-conscious design practices; the role of Borderland and Border Thinking design issues in the inclusion and leveraging of diversity and heritage in design research; and the integration of Latinx/Hispanic, African-American, and Native designers, Middle-Eastern and Asian design practices and issues as pivotal sources of inspiration. These topics were discussed only on the surface during class discussions mostly due to time constraints. They require deeper consideration in order to enrich design dialogues and to expand ethnographic practices.

In order to increase the reach and impact of this project, I’m expanding its sources and elaborating on contents, methodologies, and definitions of possible design deliverables in order to start implementing it in the graduate design classroom as well. Graduate students perform in an environment that can enrich social design thinking and research discussions by providing solutions with a more practical, real-world use. These students may reevaluate ways in which their own notion of heritage can produce stronger social awareness, better collaborations, and multi-ethnic co-creation. At this point, graduate students researching heritage and cultural diversity in design can engage in a more involved process of
interpreting content, explore its visualization, and apply critical thinking to determine how best to connect with people empathically, how to successfully craft a message relevant to a particular audience and deliver it through the most culturally-appropriate media (Alden, 2011).

Maria Gabriela (Gaby) Hernandez

Gaby Hernandez is an Assistant Professor of Graphic Design at the University of Florida. Her research interests include social design research, community engagement, and diversity in design. For over 10 years, she has developed collaborative design projects in information design, editorial design, branding, entrepreneurship, and design for development with scientists, multidisciplinary teams, non-profit organizations, minority groups, and indigenous communities nationally and internationally. Her work has been peer-reviewed, published, and presented at multiple design conferences, including the International Design Research Society Biannual Conference and the AIGA Design Educators Conference. From 2013 to 2017, she also worked as Assistant Professor of Graphic Design at the University of Houston-Downtown, where she founded and directed the Graphic Design Research Initiative, a design and mentorship program developing real-world projects with design students from minorities focusing on design research and social design. Gaby is the Education Director of the AIGA (the professional association for design) Gainesville Chapter, member of the AIGA Diversity & Inclusion Task Force, and the AIGA Design Educators Community Committee.
A Matching Test of Task-Gesture on Tablet for Mid-older and Young Adults

Chiwu Huang, Department of Industrial Design, National Taipei University of Technology, Taipei, Taiwan, chiwu@ntut.edu.tw

Abstract

Due to the intuitive controllability and easy to learn the tablet is a very popular nowadays. Many touch gestures are introduced to enhance the convenience usage on the tablet. However, how these gestures match with the tasks? Are they understood by the “technological alienation” of the elderly users? Is there difference existing between the elderly and younger people? This study aims to answer these questions. Seven basic gestures and their correspondent tasks were selected from top 3 operation systems. Thirty mid-older subjects including 15 expert users and 15 novice tablet users and thirty young subjects were recruited to do matching test. As a result, we found that the correct rate of the mid-older is significantly lower than the young. Experience in using might affect the correct rate. Certain intuitive gestures including Tap, Swipe, Pinch and Rotation had higher correct rate were considered to be acceptable for both mid-older and young subjects according to the ISO standard. However, only the Pinch gesture for novice mid-older is acceptable. The research suggests that more coaching might be needed for novice mid-older adults on the use of gestures.

Keywords: mid-older, matching test, tablet, gesture

Literature Review

Since 2010 Apple Company launched its first tablet, iPad, the market share of tablet grow up quickly. Tablets compared to desk-top and notebook computers are easy to learn. The size of over 7-inch screen is better than the small screen on the smartphone in usability and portability. It is an ideal device for older people and children.

The market share of tablets has surpassed notebooks at present. In contrast to desktops and notebooks, tablets are easy to learn and carry around which make them suitable for the elderly. Some studies found that the elderly use their eyes and hands straightforwardly and comfortably while using tablets. It does not require any IT knowledge or experience. Thus, the mental loadings of the elderly are decreased in a considerable degree. Consequently, the tablet has
been used broadly by the elderly to satisfy their needs in webpage-browsing and entertainment.

Caprani et al. (2012) found that seniors using their fingers and eyes in an intuitive way when they using tablet. They do not need any IT products’ experiences. The hand-eye coordination is much better. The intuitive operation can reduced seniors’ mental load. It can meet their needs for internet and leisure entertainment. Morris (1992) pointed out that “Technological Alienation” of seniors in the application of information science and technology, namely, operation of an existing computer, peripheral hardware and software interface used, compared with other age groups, seniors are often more difficult to control, causing psychological and physical disorders.

The maturing of the touch gesture control technology in recent years, touch gesture control is applied broadly in GPS navigation, smart phones, tablets, laptops, touch panels and other consumer electronics products. Compared with the previous mouse control device, touch gesture has become a mainstream control method, a new generation of human-computer interface interaction. According many literature, the touch-control is more intuitive, convenient and easy to learn for the elderly. However, what problems will happen when the elderly converts from traditional input interface to a touch-control operation? Will it be easier to use and give a proper feedback to the elderly. It remains a subject worth to explore.

Seven gestures were selected from the three most popular tablet operation systems, i.e. Android, Apple iOS and Windows. Seven gestures include Tap, Tap and hold, Double tap, Swipe, Pan, Pinch and Rotation. They are considered to be basic and used most often. They are illustrated as Table 1.

**Research Methods**

Matching test is adopted to see how the tasks match the gestures on a tablet. The method is described as following.

**Subjects**

Two groups of respondents, 30 mid-older adults (aged 40-70) and 30 young adults (aged 20-30), are recruited for the test. The gender are as evenly distributed as possible. The mid-older group including 15 expert users (who use tablets or similar devices everyday) and 15 novice users (who use tablets or similar devices less than once a week). In this exploring stage, the convenient sampling method is used. A $200 NT dollars of convenient store coupons was offered to every subject as a reward.

**Tools**

A laptop computer is used to play back the video clips which shows intended tasks and a questionnaire sheet were used to collect the answer.

**Experiment procedure**

1. Collect the subjects’ basic data including: age, gender, education and experiences in using tablet.
2. Seven questions in video clips are played back to the subject one by one randomly. Subjects are asked to reply respectively until finish all the questions.
3. To prevent the subjects from choosing an answer by try-and-error, tablet was not provided during the test. The subjects were asked to choose an answer intuitively.
4. The answers and reactions from the subjects were recorded by the researcher for analysis.

The following seven questions were asked randomly to avoid the guessing bias.

1. If you want to select an App item, which gesture would you use?
2. If you want to delete an App item, which gesture would you use?
3. If you want to zoom in or out a picture or a web page to its original size quickly, which gesture would you use?
4. If you want to turn a page or read the other part of a page, which gesture would you use?
5. If you want to move around an App item to make your desktop more organized, which gesture would you use?
6. If you want to zoom in or out a picture or a webpage in the size you wanted, which gesture would you use?
7. If you want to rotate a map into a direction you wanted, which gesture would you use?
Data process
The Confusion Matrix (Zwaga and Boersema, 1983), a method to evaluate graphic symbols recognition rate, was used to analyze the data. Touch gestures were looked as an analogue to graphic symbols in this study. Seven gestures were placed on the left column while the responding tasks were placed on the first row. The number of the answers was registered into every corresponding box. The final correct rate is decided by the number of correct answer by the total number of subjects. The ISO standard for acceptable symbol recognition rate 66.7% was applied to judge the acceptable correct rate for the gestures.

Results and Discussion
Thirty young subjects aged between 20-28 years old (18 males, 12 females, 23.0 average, 2.27 S.D.) and thirty mid-older subjects aged between 47-70 years old (12 males, 18 females, 60.6 average, 7.03 S.D.) were recruited to do the task-gesture matching test. Half of the mid-older subjects were novice tablet users (use less than once a week) while the other half were expert users (use every day). All the young subjects were considered to be expert tablet users.

Mid-older subjects vs. young subjects
The results of the task-gesture matching test on young group and mid-older group are shown in Table 1 and Table 2 respectively. Overall, it is not surprisingly that the average correct rate on all tasks for mid-older subjects (52.4%) is significantly less than young subjects (78.6%). Except for “Delete”, all the correct rate of every task for the young subjects are higher than their counterpart (see Figure 1). Interestingly, among young subjects, two tasks’ correct rates are below 66.7% (the ISO standard for icon acceptable recognition rate) i.e., “Delete” and “Quick zoom”.

16 subjects choose “Pan” to “Delete” an App icon, whereas only 7 subjects choose “Tap and hold”, the correct gesture. Why? In a following inquiry, we found that might be that the subjects are familiar with their own device in which the android system uses “Pan” (tap, hold and drag) as delete function while Apple IOS uses “Tap and hold”. This reveal a usability issue that the gestures for task are inconsistent over different systems. This might takes time for a new user to get used to a new system although a touch controlled tablet is thought to be easier to use. This is a confusing caused between systems.

Only 17 subjects (56.7%) choose the correct “Double tap” for “Quick zoom” task while 12 (40%) subjects choose “Pinch”, a “Zoom in” and “Zoom out” gesture. The functions of these two gestures are so similar that cause confusing caused within system.
In Table 2, four tasks including Select, Zoom-in/ out, Turn page and Spin for older subjects are over or equal to 66.7%. This means that they are acceptable for older subjects. The rest three other tasks’ correct rates including Move, Delete and Quick zoom are far below the 66.7%. This means that they might be difficult for the older subjects. The Pan (11 selected) may be confused with Swipe (12 selected).

Novice vs. Expert Mid-older

The difference between novice and expert older subjects are further analyzed in Table 3 and Table 4. The average correct rate of the expert older (60.9) is higher than novice older (42.9). In Figure 2, there is only one task’s correct rate, namely Zoom in/ out, for novice older subject is equal to 66.7%. Six out of seven tasks are below 66.7%. However, four tasks for expert older subjects are over 66.7%, namely Select, Zoom in/out, Turn page and Spin.

Figure 2 Comparison between expert older group and novice older group on gesture matching rates
Conclusion

Seven basic gestures, namely Tap, Tap and hold, Double tap, Swipe, Pan, Pinch and Rotation, and their correspondent tasks were selected from top three operation systems to examine the recognition difference between mid-older and young tablet users. Thirty mid-older subjects including 15 expert users and 15 novice tablet users and thirty young subjects were recruited to do matching test. As a result, we found that the correct rate of the mid-older is significantly lower than the young. Experience in using might affect the correct rate. Certain intuitive gestures including Tap, Swipe, Pinch and Rotation had higher correct rate were considered to be acceptable for both mid-older and young subjects according to the ISO standard. However, only the Pinch gesture for novice mid-older is acceptable. The research suggests that more coaching might be needed for novice mid-older adults on the use of gestures.

Abstract
This research expected to innovation designs can develop by more detail user-experience, that also reduce users unfamiliar and depressed; therefore, we investigated that people cognitive process on operated daily commodities, and we planned a tool to analyze users the area of contact and frequency. In experiment, we selected three objects whose size and shape are similar but haven’t limited way of operation. After that, we excluded feature of shape and make them consistent. We studied 30 participants response to operation and affordance, and analysis that by qualitative and quantitative. The result showed the participants have consistent posture of grasp, area of contact and way of operation in the same experimental situation; in addition, even the grip are the same, but following different functional parts, users still response a corresponding way of operation. So we suggest that shape only be as one of design factors on simple design style, and not the main factor. Designer should find other design techniques to enhance the user’s cognitive operation.

Keywords: Affordance, Perceived affordance, Operation process.

1. Introduction
We will contact continuously various products everyday. A great design not only provided aesthetics and function for people’s need but also has to provided users with clearer and easier operation. Even so, “bad design” still full of our life (Norman, 2002). Bad designs couldn’t provide users clearer and easier information to operate correctly and directly; hence, that affect users made a negative experience about wrong operation. Those experience will affect determinant in the users’ selection of products in future (Slovic, Finucane, Peters, & MacGregor, 2002). Therefore, designer should understand about users habit of operation and consider more detail in operation process. In the light of this, the research based on Affordance (Gibson, 1979) and Perceived Affordance (Norman, 2004) and investigates non limited operation product in life. We aim to observing consistency or inconsistency about users posture of grasp, area of contact and way of operation, when the grips the same but have different function part. the result expected that can provide a new factor of design for improve problems.

2. Literature Review
2.1 Affordance and Perceived Affordance
Design is a creative process that through product, environment and information to satisfy consumer (Cooper & press, 1995). In the process, we need to study the interaction between object and users, and that include designer and users how Interpret “the object”. therefore, first of all we have to understand users how to operate product, cognitive processes and possible behavior. And now, also many research studied the topic by affordance (Gibson, 1979) and
perceived Affordance (Norman, 1999, 2004) to developed different perspective. The concept of Affordance was explained people how is way of “direct” reaction on an object. The response doesn’t need to deep thinking processes; in addition, the response of everyone has different result on the same object (Bingham, 2000). But Norman (1999) came up with a different affordance perspective that people’s reaction will according to their experience, culture and skill. Although everyone has different perspective; but they claim have the same result that can help us to improve users process of operation (Gaver, 1991), and related researches confirmed that could effectively connected people’s behavior of cognitive by Affordance (Albrechtsen, Andersen, Bødker, & Pejtersen, 2001; Bingham, 2000). Affordance could explain the process which both user and design object interacted. When user’s aims and object’s affordance come to consistency, user will operate directly and achieve function of the product. But, not only affordance was existence or not, also important thing, the affordance was perceived possibly from people, and how to think the affordance. What is our next step? Most previous researches according either affordance or perceived affordance to studies, but in the case that will combine both to explore cognitive processes that users interact with “experience” and “situation”.

2.2 Operation behavior

Operation behavior was a action which user operated product to achieve function, for example, people grasp the pen to write words, grasp the toothbrush to brush teeths and rotate the cover of bottle to open. We observed behavior can distinguish for three part: (1) posture and area whose people grasp, (2) operation after grasp and (3) the result of operation; however, different the posture of grasp will affect to operation, but correctly grip could assist people to operation more easy. For example, chopsticks was used usually in Asia, but it hasn't consistency the way of operation. Everyone depended on their experience and habit, so have many different way, as fig 1. Although they also can caught food, but strange way will affect their success rate and fluency on operation.

![Figure 1: Different posture of grasp about chopsticks](image)

3. Research methods

3.1. Product selection

The research hoped innovative design that can according detail user-experience on operation in daily commodities; therefore, we selected knife, spoon and wrench that have similar size and shape grasp, but have different operation. After than, we exclude feature of shape and make then consistent; as fig 2.
3.2 Contact frequency
We planned a tool for record users grip area and frequency in operation process in order to explore they have consistent or not, as fig.3. Before users hold props, we have pasted Record Contact Frequency Paper on props, and we used marker pen to markup users grip area in experiment. Finally summed up all of data to analysis.

3.3. Experimental situation
We planned the props that can enhance authenticity of experiment in order to make participants to produce close to real result, as fig 4, we also planned standardized process, as fig 5.
4. Result

We recruited 15 male and 15 female participants by convenience sampling and purposive sampling, and they have to use right-handed; in addition, they have experience by knife, spoon and wrench, but No.11, 17 participants seldom use experience of knife, it lead they have different way of operation with other participants.

We through “Binomial test” to analyze the response of participants were according to “experience” or “situation”. Table 1 shows the participants operated knife and spoon mainly according to experience significant more than situation(p<0.01) that stand for most participants will follow their habit for use knife and spoon. On the contrary, the participants have different decision in operation of wrench, but most people according to situation more than experience. After that, We further analyze detail that users were according “experience” or “situation” in the process of operation by Qualitative analysis. Table 2 show the participants were in grasp posture and operation of knife and spoon, they according to experience more than situation. especially, they were in knife, wrench and spoon of grasp position, and they most according to situation; in addition, they operate knife and spoon according to experience more than situation, but wrench was opposite. The result of table 2 were consistent with the result of table 1. Most participants used knife and spoon according to experience, On the contrary, wrench were according to situation.

*=p<0.05
After that, we through Binomial test to analyze frequency which participants contact area of grip, and the statistical results are visualized and combine video data to analysis. As fig6 showed, the darker the color of the square grid, the higher the contact frequency; in addition, the white number was the area of high-frequency (p<0.05 / significant higher than 50% participants have contact), the black number was the area of medium-frequency (p>0.05), the red number was the area of low frequency (p>0.05 / significant lower than 50% participants have contact) and the gray number was the area of non-contact. Fig 7~11 was 3D visual results which analyze participants contact frequency, area and posture about knife, wrench and spoon.

Figure 10: 3D visual result of contact frequency and posture that participants grasp the posture-2 of wrench.

Figure 11: 3D visual result of contact frequency and posture that participants grasp the posture-1 of spoon.
5. Conclusion and recommendations

According to analysis results showed participant operated product will rely on interaction both experience and situation, and not only depend on either. But participants rely on the degree with experience or situation, that will be difference with different product. For example, they operated knife and spoon refer to according to experience more than situation, but they operated wrench refer to according to situation more than experience. However, more interesting discovery Even participants have different gender, background, the size of hand, product of non-limited operation, but they operation and the area of grasp come to consistency in the same experimental situation. We suggest that shape only be as one of design factors on simple design style, and not the main factor, because we considered aims more important than shape, it effectively affect their perceived process. Therefore, designer except metaphorical design, the cue of shape, printing icon to create the cue, they can try to a new way. For example, pattern design in product surface, before pattern most use to increase non-slip function. Current productive technique better and better, designer could create many complex patterns on product surface, that can provide great visual effect. But that only focus on aesthetic, we could combine more cue to improve that get more information.

Abstract

In recent years, architecture culture study is a popular direction in traditional vernacular dwelling research of China. Architectural culture, as the metaphysical part of a building, not only influences the formation of the building in design period, but also dominates the use-pattern of the building after construction. However most of studies started with material form of dwelling from architectonic prospective ignored that architecture is a phenomenon of culture. The study of vernacular dwelling from cultural and other related academic fields is very necessary. Bei-nong is a transportation space in traditional vernacular dwelling of Jiangnan area in China. This paper tried to use the methods of urban history research to investigate this space. First of all, the particular time and region of bei-nong appearance has been observed and defined from historical and cultural background. Then, appearance reasons have been analyzed based on the social context and mainstream philosophy during the scope of time and region. In the end, the physical and social functions and the architecture construction of bei-nong have been summarized and ratiocinated from the former conclusions according to inductive reasoning theory. A real and comprehensive bei-nong is showed in the result of research, not only the physical form and history of architecture but also a history story about that place and time.

Keywords: Dwelling; Bei-nong; Transportation space; Feudal ethics; Disaster prevention space

Bei-nong, an alley was designed in the Chinese traditional vernacular dwellings. The related study started in 1970s, but there is no monograph till now. The predecessor research results summed up below. First, bei-nong is a unique space in buildings of the Suzhou area (C, Z, Su. 1978; G, X, Pan.1986; S, F, Yu. 1990 and Y, D, Lu. 2003). Second, this space include the function of the fireproofing and the drainage (J, J, Hu. 1987 and Z, J, Peng. 2012). Third, this space was exclusively for the female user (J, R, Teng. 2010 and J, Zhu. 2012). However, all of these studies were established on the survey only in Suzhou City in Jiangsu Province of China. More researches of bei-nong need to be survey in a wilder geographic area and historical environment.
The definition of the appearance time and geographic area of Bei-nong

The "metabolism" of the transportation space in the dwellings

According to ancient book recordings and on-site mapping, bei-nong was a common transportation space in the whole Jiangnan area of China. Since the short life span of the wood structure, most of the architecture heritages were built in Ming, Qing dynasty and Republican China. Therefore, the limitation of the mapping sample created a misunderstanding that bei-nong excited in dwellings from the very beginning. Few people analysis the appearance time of this space.

Buildings in Chinese traditional courtyard house were set in door-halls-bedrooms pattern, and placed from front to the back one by one. This design had already been stabilized during the Chun-Qiu period of China (B.C.770-B.C.476) [1]. Attributed to this in-series layout, the inner house typical transportation method of person called across-mode was along the central axis of the house. That means you have to pass through all of the buildings if you want go to the innermost building. In the Wei-Jin period of China (A.C.220-A.C.420), the winding corridors were used to connect buildings and provided another traffic method in house but without a fixed pattern. From the Tang to the Yuan dynasty, the corridor always designed to be built along the central axis and perpendicular to the two buildings [2]. This layout formed an I-shaped or T-shaped and be widely used in official-type architecture and the dwellings. This can be proved by abundant of the jie-hua (a kind of realistic painting using ruler) such as Along the River during Ching Ming Festival and One Thousand Li of Rivers and Mountains [3] (Figure1). But these new corridors did not change the former traffic mode that crossing buildings one by one until the appearance of bei-nong.

![Figure 1: The I-shaped and T-shaped house in One Thousand Li of Rivers and Mountains by Wang Ximeng in Song dynsty.](image)

Based on the record of ancient classics, bei-nong was never recorded before the Ming dynasty.
What exactly time of the appearance of the new space and replacement of the corridors used before is difficult to trace. The earliest record about bei-nong was found in a book named *Treatise on Superfluous Things*, an encyclopedic book about garden architecture and interior design written during 1620 to 1627 in Ming dynasty [4]. This book point out that the best house on that era must have a bei-nong space, and the I-shaped layout should not be used except the official buildings. That means bei-nong had already appeared and applied in the house before 1620. According to the survey situation of the dwellings heritage in Jiangnan, bei-nong also became the normal design in the dwellings from Ming dynasty. Therefore, the appearance time of bei-nong was supposed in mid-Ming dynasty. As a new traffic space, it improved the typical transportation pattern, and had been widely used in the house during Ming-Qing dynasties.

The usual pattern in the dwellings of Jiangnan area

Different from previous research, in this study bei-nong have been found not only in Suzhou city but also in the whole Jiangnan area through the extension survey. One consensus of various definitions of Jiangnan area is about the geographical range that the core area was include Suzhou, Songjiang (Shanghai), Changzhou, Hangzhou, Jiaxing, Huzhou and Jiangning (Nanjing). This region had grown as an economic and sociocultural community at mid-Ming dynasty since they have similar culture background and closely relationship in geography and finance. Bei-nong have shown in radial structure along Taihu lake bank as the investigation of heritages quantity. Both the shape and size of the bei-nong found in Changzhou, Huzhou or other areas were same to Suzhou. Even in surrounding areas of Jiangnan, such as Huizhou, Yangzhou and Ganzhou, there are several structure similar to bei-nong were found, which have some different characteristics in shape and structures, such as Huo-xiang (shown in figure. 2).

Figure 2: From left to right, Wuxi bei-nong, Changzhou bei-nong, Yangzhou huo-xiang
Explanations of the appearance of *bei-nong*

More and more gentry moved to live in the urban

Jiangnan had become a well-developed area in China since Tang dynasty. One poem written by Hanyu living in Tang dynasty mentioned that in some years Jiangnan accounted for 90% of whole country tax burden. In the Song dynasty, the movement of economic center of country from north to Jiangnan have completed. More urbans were forming in Jiangnan. Experienced years of war from late-Yuan to early-Ming, the political and economic environment became stabilized and recovered, and Jiangnan had entered a new era of accelerated urbanization process. Due to the improvement of living condition, more and more gentry who have the enormous political and economic privileges were attracted and relocated their families from village to urban [5].

The dwellings of gentry were usually built huge and complex for their solid economic capability. These huge house always composed with many *jin*, a unit of architecture. One *jin* include one building and the front yard (shown in figure 3). Accompanied by the expansion of the building scale, more people lived in together, which lead to more transportation requirements. The typical traffic mode cannot satisfied these requirements any more. In order to improve traffic efficiency and mobility in house, *bei-nong* was created.

As figure3 shows, *bei-nong* was set paralleled to the central axis on the most left or right side of all buildings next to the boundary wall, and connected every buildings and yards in the house. Users can walked through this equal-width alley to get every building rapidly and easily. Bei-nong improved transport efficiency and traffic order of the life in the large-scale house.

![Figure 3: The architecture unit *jin*. The typical transportation method and *bei-nong*.](image-url)
A space induced by traditional feudal ethics

Bei-nong has another name bi-nong, recorded in Treatise on Superfluous Things. Here, “bi”, means avoidance in Chinese, and this name shows another explanation of the usage about bei-nong. In the actual process of using, for avoiding the master and the male guest, bei-nong was the dedicated channel designed for the slaves and female family members.

In Ming-Qing dynasties, the common people were divided into different classes, and the different classes were not allowed communicated optionally, especially from the lower class to higher class. Slave was almost the bottom class in society. It was considered as an unlucky thing or an offence if they met the master or guest without permission in the house and would be punished. This consideration and punishment were protected by the law and conformed public opinions. Bei-nong could help the slaves to avoid the master and keep the service work normally and efficiently.

The female family members is the second group of the user of the bei-nong. In traditional life of China, without the permission of husband or master, women have to stay in the room forever except a few chances in a year, such as the mothering days or temple fair. Women still need hide their faces by round fans or handkerchiefs when they take part in these activities. During Ming-Qing dynasties, these restraints for women were protected and encouraged by the gentry, religious organization and the government [6]. In fact, the female family members were always forbidden to walk around in male space located in front of the house. Under this background, many female spaces were designed in dwellings, for example, the female pavilion and the boudoir. Bei-nong with the isolation effect is another representative of these spaces, which could be used by the master to limit and control the action of the female family members.

The hierarchy and the gender difference perception were performance of the feudal ethics in real life. And the feudal ethics is the mainstream thought of the society during Ming & Qing dynasty. After 240 years of the war, the whole country urgently need a peaceful and stable environment to recover the economy and various social undertakings. The government enacted a series of statutes to emphasize the exalted position of the etiquette, the core of the feudal ethics. And the meanwhile, Zhu Yuanzhang, the first emperor of Ming dynasty, was eager to prove the legitimacy of himself because of his humble origin. He enacted and implemented new statutes to get more support and keep the stability of his governing. Driven by both demands, these statutes of etiquettes were unprecedented harshly, and the feudal ethics applied to life broadly and dramatically.

Bei-nong just was a material form of this feudal ethics. Although the birth of bei-nong was for resolve the traffic problem in the large-scale house belongs gantry in physically, but the major
user of bei-nong were the slaves and female family members for abide the statutes of feudal ethics under the influence of the social culture and ideology. Wen Zhenheng, the writer of Treatise on Superfluous Things was a scholar, painter, landscape garden designer, who came from the gentry class. The opinions in his book not only represented the thinking of the writer, but the aesthetic taste and cultural conception of the gentry. The function for upholding the feudal ethics of bei-nong was very significant to gentries, even more valuable than the traffic function.

The functions and construction ways of Bei-nong

A carrier of multiply functions

Based on the analysis of the appearance of bei-nong mentioned above, the major function of the bei-nong can be summarized in physical part and social culture part.

On the physical part, in order to satisfy transportation needs in large-scale house, bei-nong provided a fast channel, which helped people to get to every buildings rapidly in the house. As a transportation space, bei-nong improved the efficiency of the traffic and the utilization of the whole house. On the social culture part, under the influence of the feudal ethics, bei-nong was a material medium to limit and induce the behavior of people. As a spiritual space, bei-nong fostered the hierarchy and the gender difference perception. It was a reflection of the social mainstream ideology during Ming-Qing dynasties.

Besides the major function, bei-nong also was an important space of disaster prevention.

- First, for fire protection. In case of fire, bei-nong can cut off and slow done the fire from one side to another side. Meanwhile, it is a temporary safer passageway which can evacuate the people in house rapidly.

- Second, for water discharge. In most cases, on the one or both sides, drains were dug on the ground of bei-nong, which connected the rainwater head and drains of yard. Because of the straight shape of bei-nong, it is benefit to drain in rainstorm.

- Third, for defense against intruder. People can use this fast channel to stop or chase the intruder in time.

- Forth, other functions. Bei-nong always have a roof which can used to keep out winds, rains and the sun exposure. This space provides a comfort condition for walk and improves the quality of life in the house.

Construction ways of Bei-nong
As figure 1 shows, *bei-nong* is consisted of two different structures that the building-side is next to the building and the yard-side is face to the yard. The doors in *bei-nong* were only located in the yard-side. People can use the doors to get to every yards then to each buildings. According to the arrangement of buildings and yards in the house, two structures were grouped together alternately to form a *bei-nong*. The length of the *bei-nong* always equal to the length of the whole house and some existing *bei-nong* are one hundred meters long in Jiangnan area. The width of *bei-nong* is about 0.8-2.2 m.

*Bei-nong* has a successive roof. This is the most distinctive feature compared with the similar spaces found in other place of China. The roof of building-side of *bei-nong* is the continuation of the building roof. That means, there are no gable between the building and *bei-nong* in aerial view. The roof of yard-side *bei-nong* have two settings, one is single-pitch, and the other one is double-pitch just like the roof of the wing rooms.

The location of the window is selected cautiously as conventional wisdom believe it is important for concentrate strength and wealth. The side walls of buildings are not allowed to have windows. Therefore, the natural lighting for long *bei-nong* is bad. To compensate the lack of natural lighting, some alcoves were placed on the wall of *bei-nong* every meters. Oil lamp or candle can be putted in alcove to increasing the lighting in *bei-nong*. And another way to improve the lighting is add some skylights on the roof. In the traditional private gardens in Jiangnan of China, flower window on the yard walls helped the lighting of *bei-nong*, and decorated this new space.

**Conclusions**

Chinese traditional dwelling is composed of many spaces which have various forms and functions. At different periods, new spaces appeared incessantly with the development of the physical and spiritual demands. As one of these new spaces, *bei-nong* was born in Jiangnan area of China during mid-Ming dynasty, and became the normal setting in traditional dwelling. *Bei-nong* improved the efficiency of the transportation in house, and reflected the social mainstream ideology during Ming-Qing dynasties.

This study draw on the research methods of urban history and sociology to investigate the architecture space. More attention paid to the causality between architecture and historical background. In the survey of this research, several spaces similar to *bei-nong* was found, such as *huo-xiang echo-xiang*, and more study is still needed.

Abstract

The technique and philosophy of traditional crafts are relevant aspects of our culture that should be passed on to future generations. However, using traditional crafts in modern life in their original form can be a challenge. It is essential to reinterpret them in the modern context, keeping the essence of tradition. For this purpose, we conducted case studies of Koishiwara and Yame in Fukuoka Prefecture, Japan, where Japanese traditional crafts are still manufactured. We used Koishiwara Pottery and Yame-Fukushima Buddhist Altar manufacturing as our investigation objects, conducted studies on their historical background and performed detailed observations of manufacturing techniques and processes. Thereafter, we developed the concept of “KATA” in Japanese, generally translated as type or prototype. “KATA” has several other meanings; in this study, we subdivided the concept into three elements, namely, shape, pattern, and style. We used “KATA” to build a framework to be used as a scaffold to help analyze the techniques and background of traditional crafts and reinterpret them to design products in the modern context.

Based on reinterpretations, we developed a series of prototypes of modern tableware with the essential techniques of traditional crafts to verify the usefulness of the framework.

Keywords: traditional handicraft, modern life, shape, pattern, style, Kata

The decline of traditional crafts is a common problem in modern industrialized countries. Wisdom, technology, and thought that traditional crafts have inherited for hundreds of years are important aspects of regional culture. However, with the emphasis on advanced mass production technology and convenience, many of the traditionally produced products are not suitable for modern life in terms of function and preference. These products have gradually disappeared from our daily lives, and their demand has drastically decreased. Furthermore, in terms of economy, prices commensurate with the time and labor involved in traditional crafting are less competitive compared to the price of mass-produced goods.

The starting point of our research was the motivation to inherit the wisdom and technique cultivated over generations in everyday lives as practical goods, by adapting them to our modern life, and evolving them as modern life culture. Therefore, traditional crafts must be transformed to products that are functional and culturally compatible in our age. We explored the techniques and spirit of traditional crafts and tried to find ways to design products including the essence of traditional crafts, which are valuable in our modern daily life to pass our heritage to future generations. This paper aims to discuss a framework that serves as a scaffold for designing traditional crafts in the context of contemporary life.
Literature Review

Three approaches are prevalent in studies that aim to pass on traditional crafts in the future. The first approach discusses how to establish the market economy of traditional crafts, as Rovine (2008), and Rogerson and Sithole (2001) have discussed. The second approach focuses on the method to archive traditional crafts as cultural heritage, noted by researchers such as Manitsaris et al. (2014) and Ide et al. (2005). The third approach focuses on how to use digital technology in the traditional crafts design and production process such as Ishida et al. (2005), and Zoran and Buechley (2013). The first approach concentrates on developing countries where handicraft is viewed as one of the major industries, and a few studies have been conducted on cultural aspects of industrialized countries. The second approach regards traditional crafts as cultural heritage and art objects; the viewpoint of a product closely related to modern life has disappeared. The third approach opens up new possibilities for traditional crafting; however, the perspective of the inheritance of culture and techniques is limited.

Research Methods

We took advantage of the opportunities of design practices in real projects, experimented with a new research process and theoretically studied it. Specifically, based on qualitative research by employing ethnography techniques, we described details of the selected traditional crafts, such as the production process, techniques, lifestyle of manufacturers and their families, and workshop management. Subsequently, we understood the products themselves and the mechanisms that support manufacturing. Based on these findings, we examined the framework that can be employed as a scaffold for acquiring insight and ideas. Using the framework as a scaffold, we developed the design concept, carried out prototyping and implementation and reviewed the process to verify its usefulness.

We focused on two regions in Fukuoka Prefecture in Japan, Koishiwara village and Yame city, and conducted a two-step survey. The former area is known as a pottery (Koishiwara Pottery) production area and the latter by many kinds of traditional crafts such as Buddhist altars (Yame- Fukushima Buddhist Altar), paper lanterns, stone lanterns, Japanese paper, and woodwork.

We dealt with Koishiwara Pottery and Yame-Fukushima Buddhist Altars. The survey and practice of Koishiwara Pottery was regarded as the basic research to formulate a hypothesis, and the survey and practice of Yame-Fukushima Buddhist Altar was employed to modify and verify the hypothesis.

Discussion

Lifestyle of Koishiwara

The Koishiwara area is in a basin with an altitude of 400 meters and is surrounded by
mountains. It was once a crowded town village because of traffic and a pilgrimage to Hikosan, one of the most important religious mountains in Japan. However, after World War II, the population decreased and currently, it is recognized as a very depopulated area. To come to an understanding of the lifestyle found in Koishiwara, we observed a community of four craftsmen and their families by means of the participatory observation method. This survey commenced in 2007 for one year, although intermittently. The findings of this survey are as follows:

Livelihood:

• Most of the pottery workshops are managed by a couple of people in a family. They conduct pottery workshops and agriculture at the same time, both of which form the basis of their livelihood.
• They mainly manufacture tableware for daily use and sell it at affordable prices.
• Although sales have declined compared with the booming economic period between the 1960s and 1980s, they maintain a livelihood but feel uneasy about the future.

Lifestyle:

• The consciousness of the community is strong, and village people, including potters, enthusiastically participate in the activities of the community such as festivals and unions.
• There are many opportunities to gather and eat together in large numbers with families and friends.

Values:

• All four craftsmen were born into potter families, attended college in urban areas, and returned to their hometown to follow in the footsteps of their families.
• They are proud of living in Koishiwara and being the successors of traditional potter families.
• Boys of potter families tend to respect their fathers’ work and want to be craftsmen too.

History of Koishiwara Pottery

In the Koishiwara area, approximately 50 potters’ workshops are currently in operation. There remain 16 kilns ruins that were built in the 17th century; the pottery production began around that time. In those days, craftsmen worked while traveling in the vicinity searching for soil suitable as raw material for pottery. Consequently, Koishiwara Pottery historically had two types of potteries, namely, Takatori Pottery and Nakano Pottery. Takatori historically produced tea cups for tea ceremonies with a traditional aesthetic sense while also manufacturing life tools used in daily life. Nakano manufactured large-sized ceramics such as pots, jars, and other large vessels.

Findings from history reveal the following:

• Pottery not used as artwork but on a daily basis was mainly manufactured.
• There is a history of producing large vessels such as pots and jars because of suitable soil and techniques.
• These are produced while responding flexibly to the natural environment by using locally available materials.

Koishiwara Pottery techniques

While visiting four pottery workshops and observing the production process, we interviewed the craftsmen and surveyed the techniques that were handed down to Koishiwara Pottery. The findings are as follows:

• All products were manufactured by handwork, using potter’s wheels.
• As a pattern of decoration on the surface, “Tobikanna,” “Kushime,” “Hakeme” and so forth are often used (Figure 1). There are many techniques to make patterns while rotating a potter’s wheel.

![Kushime and Tobikanna patterns](image1.png)

Figure 1: Koishiwara Pottery decoration on the surface

• Glazes are made individually in each potter’s workshop using raw materials such as patina, rust soil, wood ash, and straw ash. Straw, in particular, is a by-product of agriculture.

Insights from the findings

Based on the findings of the survey, insights were deduced by the designer of the project team and the design students. We categorized the insights according to the thinking process of design. Identity: Conditions to be met when designing

• Using soil of the Koishiwara area
• Use of natural glaze, which can be taken from the Koishiwara area
• Production using a potter’s wheel

Techniques and modeling: Physical characteristics of Koishiwara Pottery that can be applied to modern products

• Mass production within the scope of handicrafts
• Techniques and raw materials to produce large-sized pottery
• The existence of successors who will hand down their skills
Lifestyles: Contexts, meanings, and values that can be applied to modern products

- Strong community consciousness and opportunities for eating together
- Manufacturing tableware for daily use

Application of the insights framework for concept-making and prototyping

Working together with the designer and the design students of the project team, we developed a concept based on the categorized insights above, produced a prototype, and reviewed the process.

Figure 2-4 demonstrate the prototypes of a new dishware series of Koishiwara Pottery. The design concept was “Timeless and Share.” “Timeless” was conceived from the fact that the potters will have successors, which will enable the continuation of the production of the same type of products and supply necessary quantities of the products at the needed time. “Share” is a concept that suggests a rich lifestyle in the modern age, conceived from the habit of eating and spending much time together with many people because of the strength of community consciousness of the village. The concept of “share” is physically supported by the traditional techniques that can produce large-sized pottery. It enables us to design a large plate with a diameter of 40 cm. Three or four circular dishes are made separately and combined with each other to produce one large plate by using the traditional technique of making large-sized vessels. This shape is suitable to use for different kinds of foods, which encourages users to enjoy their meal by sharing foods and their time.
From consideration to hypothesis

By listing the findings obtained from the survey and sharing them in the project team, we confirmed that effective insights to develop design concepts and apply them to physical prototypes can be obtained. However, this method of categorizing is specialized in the case of Koishiwara Pottery and unsuitable for wide use. Considering that the succession of traditional crafts is not limited to a specific area and is a general problem that many modern industrial countries experience, formatting the flow from findings to insight and applying it to other cases is needed. It would be effective to make it function as a scaffold for setting up a framework from which to obtain ideas. Therefore, inspired by Alexander (1964), we proposed a hypothesis: Structuring based on the concept of “KATA” is effective. The word “KATA” in Japanese means prototype in the manufacturing process and is an essential aspect of ensuring the productivity and quality of product-making. However, “KATA” is essentially a compound word that means shape, pattern, style, form, format, type, mold, and so forth. We focused on the elements that constitute a product: the form, surface, and usage/meaning. Therefore, we decided to draw ideas from three concepts of “KATA” as a framework: shape (formative design), pattern (surface/decorative design), and style (usage/cognitive design).

We applied this framework to Koishiwara Pottery; this is thus described:

Shape: round shape made by potter’s wheels/large-sized vessel made using hard soil from the Koishiwara area

Pattern: rich variation of glazes made from natural raw material from the Koishiwara area/various decorating techniques

Style: handmade semi-mass production/sense of belonging to the community
Our hypothesis is that the three elements of “KATA,” namely, shape, pattern, and style, can be used as a framework to be employed as a scaffold to consider the design concept, shaping, and functions and to create variations. Furthermore, it is easy to classify the characteristics in other cases and it also has a high affinity with database creation. In the next step, we examined the effectiveness of this hypothesis by designing a diversion of Yame-Fukushima Buddhist Altar techniques.

Application of scaffolds in design project of Yame-Fukushima Buddhist Altar

The production of Buddhist altars in the Yame region began in the 19th century; the manufacturing techniques handed down to the present age were established in approximately 1850. The production of Buddhist altars comprise more than 80 manufacturing processes, which are divided among six craftsmen. As there are many complex, technical, and modeling elements, and the division of labor is well-structured, we believed it was suitable as a case for testing our hypothesis. The six steps of manufacturing Buddhist altars are as follows:

1. Constructing the wooden basis
2. Crafting the “mini-shrine” structure
3. Carving the wooden decorations
4. Making decorative copper clamps
5. Gold and silver powder decoration
6. Painting lacquer/gold gilding/assembling

We focused on the first step, namely, “constructing the wooden basis” and the final step of manufacturing a Buddhist altar, namely, “painting lacquer/gold gilding/assembling.” Using the framework of shape, pattern, and style as a scaffold, we conducted a detailed observation survey of the manufacturing process and culture and conducted interviews with craftsmen. We examined the findings obtained from the series of surveys, which are thus summarized.

Shape:
- A delicate shape that can be produced by cutting the timber to make a contour and minutely shaving it by hand
- Techniques to efficiently mass produce parts of the same shape with handwork using prototype
- Technique to prevent warpage by using specially prepared plywood

Pattern:
- Lacquering techniques such as “fuki-urushi,” “gold gilding,” and “maki-e”

Style:
- Using and maintaining lacquered products over generations
Based on the findings classified by the framework of the three elements of “KATA” as a scaffold, the project team members, including the designers and non-designers, reinterpreted traditional techniques and thoughts in the context of modern life. We came up with an idea to use the techniques of wood cutting, lacquering, and gold gilding (used for making Buddhist altars) to make cutlery and trays. Using wood processing techniques that can produce efficient delicate forms with wood, a manufacturing method for plates which do not warp over time (shape), and lacquer, which lasts long and maintains the product (style), it is further thought that surface variations in the product using various lacquering techniques (patterns) will bring new value in modern life. This product conceives ideas from approaches to understand the manufacturing process in the framework of “KATA.” The completed cutlery and tray prototype are shown in Figure 5.

In the Yame-Fukushima Buddhist Altar design project, we further expanded the concept of “KATA” and applied it, not only to the design of the product, but also to the communication design to spread the idea. The exhibition design in New York and the graphic design of a brochure for public relations are displayed in Figure 6-7, respectively.

Figure5: Cutlery and tray series made by using techniques of wood cutting, lacquering, and gold gilding. Shape: Five types of shapes with five types of surface decoration (pattern). By unifying shapes, the difference in the pattern of the surface decoration stands out. Pattern: As clearly seen, variations due to five types of decorative techniques, clear, rubbed lacquer(fuki-urushi), semi-lacquer, all lacquer, and gold gild are displayed and surface processing and decorative techniques are explained.
Figure 6: Exhibition design. Style: Presenting usage scenes on the wall explains how to use unfamiliar products overseas. The product series are displayed to show the aspects of shape and pattern.

Figure 7: Graphic design. Shape: Part surrounded by green. Style: surrounded by blue. Pattern: Part surrounded by orange.
As noted previously, the “KATA” framework focusing on the three elements was useful as a scaffold in the process of product design for aspects such as survey, design concept formulation, idea consideration, and communication design. Using the “KATA” framework as a scaffold helped create a simple, unified product system that reflects traditional essence and enables clear communication with potential customers.

Conclusion

This study aimed to interpret traditional crafting techniques and methods in the context of modern life and to present a framework that can be employed as a scaffold for designing. While designing the Koishiwara Pottery case and organizing the findings obtained from a qualitative field survey using ethnography, we formulated a hypothesis of “KATA” framework consisting of three perspectives, namely, shape, pattern, and style. Using this in the design project case of Yame-Fukushima Buddhist Altar, we examined the usefulness and possibilities of the scaffolding based on the hypothesis; consideration was given to the structure of the survey, thinking process, and inspiration. It was also suggested that it supports as a scaffold, not only for designing products, but also for conceiving and implementing a consistent design from product development to exhibition, as well as communication design with consumers such as various printed materials.
Acknowledgements

I would like to thank K. Shirotani, T. Shiramizu, H. Nakaniwa, R. Watanabe, R. Aoyagi and Y. Kumagai for useful discussions and design practices. I am grateful to Yame Chamber of Commerce and Industry for organizational work for the research project. This work was supported by JSPS KAKENHI Grant Number JP16K00712.

Abstract

Design oriented educational institution around the world, project-based learning is well practiced in local setting as well as global setting. Communication is one of the significant aspect in this learning settings. Currently, many design projects are implemented by members beyond their belonging organization, creating difficulties in face to face communication, especially when members are in different countries. This study proposes a new method for project-based learning in design education program implemented on international design workshop and discuss about outcome through empirical program.

This method is composed in three phases. First phase is online pre-workshop session using SLACK, where each member do their own researching and surveying on the specific topic related to the project, share and discuss them with other members. The second phase is face to face workshop, which all members gather in one place to work on the project intensively to make their group design proposal. The lastly in the post workshop phase, each member get back online to make reflection on the project, feedback them on the proposal, and make improvements. Also, compile and publish a project reports on the overall program for documentation. Through out the program, SLACK platform is used for basic communication and sharing data and information. This program are operated in an international design workshop called “Global Design Workshop” of Chiba Institute of Technology(CIT, Chiba, Japan), with students from Chiba University(CU, Chiba, Japan) and Tunghai University(THU, Taichung, Taiwan). The theme of the workshop was “New work place, space, style using IoT technologies.

Project-Based Learning, International Design Workshop, Multilingual Communication, Online Discussion Platform, ICT, Education

Design oriented educational institution around the world, project-based learning(PBL) is well practiced in local setting as well as global setting. Exchanging the thought and making discussion over specific topic to find and solve the problem is the major goal of PBL education requires high level communication skills. Communication among participants is one of the significant aspect of this learning style. On the contrary, especially in the international scene, IASDR 2017communication is one of the highest barrier for people using a language other than one’s native one. In this study we propose a method for efficient communication among participants and effectively facilitating PBL program where language commonly used are not their native one.
International design workshop program held in summer of 2016 at Chiba Institute of Technology are used for empirical case study for this proposed method.

1. Literature Review

The major problem in this study is how to overcome communication difficulties among people of different native language and cultural background. These problem are described in the literature. First of all, most of the communications are established by linguistic abilities but also depends on the context of their belonging culture. The context culture are roughly dived into two parts: high context culture and low context culture. A communication in high context culture, most of the information are already in person, so the information within the message is implicit. On the other hand, communication in low context culture is totally opposite of one of high context culture, the information in the message is explicitly conveyed. (Hall and Hall, 2001; Hall, 1976)

The communication between members mixed from both high and low context culture, one from high context culture tends try to create comfortable zone for communication. (Suderman, 2006) In the high context culture, people tends to expect context consistency, so communication between people who don’t share common context, disparity in perception appears, resulting possibility of generating difficulties in smooth and proper communication.

Referring to Hofstede’s Cultural dimensions theory by Greet Hofsted, “Uncertainty Avoidance” is the dimension which related to stress level in a society facing an unknown future and dealing with tolerance for ambiguity. (Hofstede, 2011) The reference states that Japan is one of the country with higher Uncertainty Avoidance Score which means Japanese culture which accept uncertain information covered by high context culture. At the same time, Taiwan shows similar pattern but there are small gaps in between. Taiwanese are also have high Uncertainty Avoidance Score but lower than Japanese.

In the low context culture, communications are taking place within the precondition that they share no unique context. Therefore, this is the culture where even though people do not know
the context on the other side, try to present their idea correctly by using gestures and words actively. But on the other side, high context culture relies on the close and long relationships between people sharing unique context constructed through long period of time, to communicate with less stress and more ambiguity. But when communication happens where this kind of relationship does not exist, there are hard time making communication. Because Japanese have high context culture, there are hard time doing group collaborative work, with less linguistic clue and no unique context is shared. Also, in uncertainty avoidance perspective, especially Japanese students, when they propose a new idea, surrounded by uncertain condition takes very careful and cautious approach. In other word, people’s action tends to be suppressed under context are not understood or have differences in high context and high uncertainty avoidance culture.

Under the circumstances of high context and high uncertain avoidance index situation, it can be predicted that misunderstanding and or mislead of context and uncertain situation might occur in international workshop. In this study, we proposed a methodology which supports and overcome communication difficulties caused by cultural differences using SLACK for online text chatting tools and SONY MESH for simple and comprehensive prototyping tools. (Figure 1)

Figure 1. Communications in High and Low Context Culture
(UAI: Uncertainty Avoidance Index)
2. Methodology

Workshop Outline

This workshop program were held in the summer of 2016. Participants consist of three university, 14 students from Tunghai University (Taiwan), 7 students from Chiba University(Japan), 16 students from Chiba Institute of Technology(Japan). Along with the participants, 8 teaching assistants and 2 faulty members from Chiba Institute of Technology for facilitating the overall workshop program. The theme of the workshop “New Design of Work Place, Work Space, and Work Style using IoT(Internet of Things) Technology.” Through out the workshop, slack is used for communication tools and SONY MESH for rapidly prototyping design idea for actualization.

The program consists of three phases. Figure 2 shows the outline of the overall design workshop. First phase was Pre-Workshop, which started on slack platform from beginning of July, 2016. Here, the following discussion topics are given to all the participants: “research and share information about present situation and future outlook of IoT(Internet of Things) technology in design field.” Second phase was Design Workshop, which all the participants meet face to face for five days at the workshop venue in Chiba Institute of Technology(Japan) from August 29, 2016 to September 2, 2017. Figure 3 shows the outline of the five days.
workshop program. And the last phase is Post Workshop which all the communication goes back online on slack. This phase started right after the phase 2 face to face workshop, continue on with their discussion on the proposal which they made for further brush-ups to apply for some arbitrary design competition. Also archive booklet making are done parallel, contents, book design, layout and graphic design all done by the participants.

Figure 3: Outline of five days “face to face” design workshop

Method of Communication

Basically, common language used during the workshop is English. Participants are all non-native English speakers. So to support their communication difficulty we prepared and stated some tools and method for efficient communication among participants.

Slack are being used all through pre-workshop to post workshop for mode of text communication, which help log and record the discussion processes. Also, texting makes some time lag during conversation allowing participants to look up unknown words or phrases in a dictionary or other mode of translation to understand and respond to the statement more precisely than immediate conversation.

Sketched and gestures are also used during the face to face workshop. Because we are dealing with design topics, sketches are very efficient way of communication to tell other participants idea.
3. Discussion

Using SLACK for sharing and recording idea with texts

Though out the whole workshop program, SLACK acted as not only a chat tool but a media for communication. During the face to face workshop, in the first instance, communication difficulties appeared among all the members. Especially speaking in English is the hardest. But as workshop get underway, they started to text the idea. First they write the idea with their own native language and by using online translation service translate the idea to tell and text on SLACK and or write them on paper or stickies to share. The merits of this method are they can share and record the ideation process at the same time so that they can occasionally look back to trace the discussion and also generate some time lags during the communication which helps member to have time to understand what other member is thinking. Demerit is having difficulties to make immediate discussion over a topic. But to share idea avoiding the uncertainty of the contents, slow discussion is better to make the situation robust idea sharing is important to develop and make sophisticated proposal.

Figure 4. Active group discussion during face to face workshop

Using SONY MESH Prototyping Tools

During this workshop, SONY MESH are used to prototype and actualize the idea that they come up with. Most of the members are not very used to this prototyping tools, so first half of the workshop program was simple prototyping workshop. They learn the function of the tools as sensors, actuators, and algorithm in between to actualize their idea. The logic flow are visualized and actualized with the MESH(electronic tags) and visualized on graphical programming MESH application on Apple iPad. This helped participants to discuss and share their idea by not using the verbal communication which is the biggest barrier between them. Actual moving prototype made instantly and shared in front of them help accelerate the members to understand, discuss, and develop their ideas closer to actualization.
4. Conclusion

In this study, we have proposed a new method for project based learning in international workshop setting. As a result, there are two parts. Firstly, for communication, using online group communication tool such as SLACK is effective in high context and high uncertainty avoidance index culture. Sharing idea and information and doing discussion beforehand during the online pre-workshop will help participants to share idea and make discussion immediately and smoothly transfer into face to face workshop phase. Especially, when participants are from high context culture like Japanese and Taiwanese are most helpful which results in upgrading quality of the workshop program itself.

Secondly, using prototyping tools such as SONY MESH will help simple and easy prototyping. Presenting the actualized idea using prototyping tool will help other members to understand the idea presented with minimal verbal communication. By looking at actualized prototype tell more than describing it verbally and will help minimize the mental stress of feeling difficulties in verbal communication.

In future studies, we want to test the method with the members from both high and low context culture to make comparison studies. The communication difficulties will be more apparent
in this situation. Also, consider the development of method to observe the situation to IASDR 2017 acquire evidence data and qualitative and quantitative analysis method and test statistical significance to make this method more versatile.

Proposal for Design Support Application Based on Extended ADT Model

Namgyu Kang, Future University Hakodate, Hakodate, Japan, kang@fun.ac.jp

Abstract

Understanding the user’s situation is very important in the design process. There are many ways to understand a user’s situation – a designer might observe a user’s situation or a user might record their own situation in Human Centered Design (HCD) file. However, the latter of these methods has not been very popular mainly because of the burden it place on the users. This research proposes a new smartphone-based design support application, named “HN camera”, which can be used to record the users’ situation, without any additional burden on them. This application is based on the ‘Extended Alethic/Deontic/Temporal (ADT) model’ concept. A user or a designer can understand and record the user’s situation based on the Physical factor, the Kansei factor, and the Cultural factor using HN Camera. The application was used in visualizing and analyzing tourists’ travel as a service design. Through this, the effectiveness of the proposed application was clarified.

Keywords: Support design, Observation, Service design, Application, Smartphone, Extended ADT model

1. Introduction

As users’ situation with various products and services become more complicated, it is all the more difficult to clarify the user’s potential needs through some questionnaire surveys alone. Understanding a user’s situation is very important in the design process. There are many ways to understand a user’s situation – a designer might observe a user’s situation, or a user might record their own situation in a Human Centered Design (HCD) file.

According to Matsunami, our needs are divided into overt needs and potential needs. Overt needs are clarified (=verbalized) with a questionnaire survey. However, potential needs are difficult to clarify through such a questionnaire survey. Group interview, in - depth interview, and behavior observation are useful to clarify potential needs [1].

Consequently, many studies about the possibility and value of observation have already been conducted in HCD design field, and the significance of this observation process increases not only in the design education but also in the work process in design companies [2]. In particular, digital cameras have become compulsory equipment in the observation process in the design field as they can be used easily record information with high quality. Furthermore, not only designers but also anyone in general can record observation results with smartphones equipped with high-quality cameras, and share the recorded information with others using Social Network Service (SNS) etc.
Previous researches about idea-creation in the design field have reported that a designer’s living experience abroad as an internal factor that has positive influence on interpretation and use of information as an external factor [3]. This means that these learned experiences in different environments are related in finding and interpreting some problems, and were involved in the idea-creation process. For these reasons, there are many cases where the observation process based on the user's viewpoint is incorporated into the design process. In the service design process, the way of finding and interpreting of problems various, depending on the perspectives of the service provider and the service user.

Based on this background, Kang’s research team has been working to improve the quality of observed information by incorporating the Alethic/Deontic/Temporal (ADT) model [4, 5] into the design process. In addition, HN Camera, which is an application to support the observation process using smartphones, has been developed by Kang’s research team.

The purpose of this research is to examine the effectiveness of this application in the observation process, based on consideration of the case study where the proposed HN Camera application was used for visualizing user’s various needs during a tour of Hokkaido in Japan.

2. Literature reviews

2.1 Different viewpoint on observation process

As previously mentioned, the observation process helps designers to create a new idea to solve a problem in our daily life. According to James and Brown, it is very important in a creative process to have a different viewpoint in observation. Ashikawa’s research team reported that personal characteristics influence the process of knowledge activation in creativity work. A different viewpoint in the observation process reveals unexpected users’ needs such as potential needs. However, the personal viewpoint, which is formed through one’s various experiences, is hard to change suddenly. These previous researches highlighted the importance of different personal viewpoints in the observing process.

2.2 Extended ADT model

According to the Suto’s ADT model, which was developed based on the relationship with an artifact, the designer, and users, there are three layers in the design model: 1) Main layer reflects the user's possible states and operations; 2) Top layer reflects the designer's intentions; and 3) Base layer reflects physical laws. It means that the user’s behavior is affected by physical laws and is restricted by designer's intention. Designers need to observe the relationship between cause and effect in design. In other words, designers must observe the user’s experience, based on the relationship with physical laws and the user’s behavior.
In ADT model, user's behavior is affected by physical layer as base layer. However, our behavior is strongly concerned with our emotion situation. Moreover, our behavior is closely related to our culture. Based on this idea, the extended ADT model concept was proposed [Fig.2].

In the base layer, restriction from environment is described. These restrictions are based on three factors: physical factors, emotional factors and cultural factors. The top layer represents designers' intentions which might differ, depending on the individual. The outcomes of their work are shown on the main layer. The circles on the main layer indicate the set of possible solutions of each designer. Design works should convey designers' intention under restriction from environment.
3. Proposal for HN Camera

HN Camera has the advantages of digital camera, smartphone camera and instant camera. They are easy to use without any special experiences, can record repeatedly, and offer the convenience of connection to SNS using the internet. By using a mobile photo printer, the recorded information is printed out immediately, and the printed photos are easy to use for the KJ method for creating design concepts as well (Fig.3).

If a user notices some information when conducting an observation, he/she can record this information, evaluating the physical, emotional and cultural factors immediately. When the user does not have enough time to record the information, he/she can later pick up photos from his/her gallery folder of smartphone and record it slowly. Each detailed explanation is shown in the following Fig. 4, 5 and 6.
When the user notices some information from observation, he/she can tag using physical, emotional and cultural factors. And, each factor can be checked and evaluated as positive or negative using the different color buttons (Fig.5). Moreover, he/she can write some reasons about why he/she wanted to record the situation, and can check and evaluate as positive or negative using the different colors (Fig.6). These different color images are saved and help the designer to easily grasp a whole evaluation construction.
4. Experiment using HN Camera

Based on the request from the Hokkaido southern area (Hakodate, Nanae, Shikabe, and Mori), the evaluation experiment was conducted with four groups (18 persons) to understand the tourists’ actual situation as they visit Hokkaido southern area, and visualize their various needs. The study made use of not only questionnaire method to clarify the conscious and verbal information, but also HN Camera application to visualize the rich information provided by tourists during their sightseeing Hokkaido southern area. The Fig. 7-10 show the results of the evaluation experiment.

The results from this experiment were discussed with some public officers of Hokkaido southern area and managers of hotels and restaurants in Hokkaido southern area. They answered that the results using HN Camera with time-checking was very helpful to grasp tourists’ situation. Especially, they evaluated that the organized images with different colors and tagged with three factors based on the extended ADT model concept was very useful to understand tourists’ needs as compared to the questionnaire method alone. Moreover, they answered that the number of recorded information in a place is important to understand the current service situation, and develop or create new attractive service design.

Fig. 7 A part of example of recording of a restaurant in Hokkaido without time check
5. Summary

Understanding the user’s situation is very important in the design process. Actually, user's needs in the service design field such as travel was said to be harder to visualize and clarify than product design, using only questionnaire method. However, it is easier to understand and grasp the user’s situation or various needs by using HN Camera.
application based on the extended ADT model. Especially, taking a photo during travel is a very natural behavior for users, so participants did not feel any additional burden in recording some information using HN Camera in evaluation experiment. As a result, the effectiveness of the proposed application was clarified. In the future, our proposed application will be developed through further experiments.

Abstract

The rapid development of IoT technology has accelerated the growth of smart services. Despite the proliferation of smart services, academic research is still in its early stage particularly in terms of service experience and service design. Concerning a service experience viewpoint, it is essential to consider the context and environment of smart services, namely “smart servicescape,” as this can influence users’ entire experience. Moreover, the smart servicescape will have different characteristics due to the convergence of online and offline connected environments. With this background, this study aimed to propose a framework for the smart servicescape by identifying new dimensions that reflect the characteristics of smart services. Accordingly, an initial analytic framework of service experience blueprint was established on the basis of the conventional servicescape and service blueprinting. Twenty movie clips on smart home services officially produced by ICT corporations were collected, were analyzed through grounded theory, and were classified according to the analytic framework. Through a series of qualitative analysis, the framework structure was improved to make it more suitable for the smart servicescape. Finally, this study proposed a framework for the smart servicescape derived from the smart home service experience blueprint. The values of this framework can be identified in two aspects: (1) by identifying new dimensions to reflect the characteristics of smart services such as Smart device, Datascape, and Connected scape; and (2) by suggesting the structure of the service experience blueprint infused with the perspective of service experience, which consists of service encounters and the servicescape.

Keywords: Smart Servicescape, Service Experience Blueprint, Smart Home, Smart Device, Datascape, Connected Scape
Rapid innovation and development of information and communication technology (ICT) has accelerated the growth of smart services based on ubiquitous computing and the Internet of Things (IoT). In B2C industries, in particular, various smart services are emerging and expanding their boundaries such as the smart home, smart health, smart media, smart learning, smart car, and so on. Accordingly, more people are paying attention to the adoption and application of smart services and how to use them effectively and naturally in their daily lives. Compared to this proliferation of smart services, academic research is still in its early stage (Wuenderlich et al., 2015). Due to its technology-intensive characteristics, previous research has primarily focused on the development and application of smart service technologies in the engineering field (Wang & Song, 2017). Moreover, the acceptance and usage intention of smart services have been researched in the service management field (Canhoto & Arp, 2017). However, there has been little research on smart services from the perspective of service experience and service design.

In the service management field, research from a service experience viewpoint has emphasized the context and environment in which service interactions take place as well as the service provision itself (Akaka & Vargo, 2015). Service is usually delivered through direct or indirect interactions between customers and firms—namely, service encounters. Focusing on the service provision itself has underscored these service encounters, as each customer can experience different encounters according to their past experiences, preferences, or diverse service providers (Bitner, 1990). Meanwhile, the physical and social environment in which these encounters occur—that is, the servicescape (Bitner, 1992; Rosenbaum & Massiah, 2011)—can also influence how customers experience the service differently. Therefore, focusing on service experience could require the perspectives on phenomenology and social structures that influence the whole experience (Akaka et al., 2015). In that sense, Akaka and Vargo (2015) asserted that the service context in which service experiences are generated consists of service encounters and the servicescape.

Similarly, for smart services from the perspective of service experience, it would be essential to consider the context and environment of smart services—namely the “smart servicescape.” Yet, the smart servicescape would have a different nature and characteristics from the conventional servicescape due to the convergence of online and offline in connected environments. This is also because advanced network technology has enabled real-time data collection and continuous communication of intelligent objects and environments with users (Allmendinger & Lombreglia, 2005). Nevertheless, research on the environmental dimensions of smart services—namely, the smart servicescape—is scarce. Hence, this study aims to propose a framework for the smart servicescape by identifying new sub-dimensions that reflect the characteristics of smart services.
According to this research aim, the article begins with a literature review on the conventional servicescape to which smart servicescape can refer about concept and dimensions. Moreover, due to the lack of smart servicescape literature, the process of identifying new dimensions requires a grounded theory approach that observes users’ service experiences. Thus, the literature review also focuses on service blueprinting to be adopted as an analytic framework for service experiences. Next, the research method illustrates the process of establishing a framework, focusing on the case of smart home service. The outcome of smart servicescape framework is described in a discussion section, followed by a conclusion.

**Literature Review**

**Servicescape: the environmental perspective of service context**

As previously introduced, the servicescape is a manmade physical and social environment in which service encounters are framed (Bitner, 1992). Bitner (1992) extended the service context from the firm-customer interaction to the environment-user relationship and emphasized the influence of physical surroundings. She categorized the physical environment into three dimensions: (1) ambient conditions (background characteristics of the environment such as temperature, lighting, noise, music, and scent); (2) spatial layout (the ways of arrangement/size and shape of machinery, equipment, and furnishings; and the spatial relationships among them) and functionality (the ability of the same items to facilitate performance and the accomplishment of goals); and (3) signs, symbols, and artifacts (explicit communicators displayed on the exterior and interior of a structure).
Table 1 exhibits the servicescape dimensions that many researchers have investigated based on Bitner’s servicescape categorization in different service sectors such as leisure, hospitality, and restaurant. Particularly in smart services, the equipment or artifacts, such as smart devices, could be a critical element, so this study adapted the preliminary components of the physical servicescape as (1) equipment, (2) space, (3) ambience, and (4) design aspect. Moreover, the social aspect of the servicescape, namely the “social servicescape,” was added to this environmental perspective to include non-commercial or social relationships such as indirect interactions with other customers, the need for connectedness, and social density, as well as direct interactions in the form of employee-customer support (Johnstone, 2012; Rosenbaum & Massiah, 2011; Tombs & McColl-Kennedy, 2003). Accordingly, the initial elements of the social servicescape in this study were defined as (1) the in-service relationship and (2) the non-

commercial relationship. Meanwhile, Rosenbaum and Massiah (2011) additionally proposed a socially symbolic (e.g., ethnic symbols) and a natural (e.g., nature and wildlife) dimension, but they were excluded in this study due to their low relevance to smart services.

**Service Blueprinting**

The process of identifying new and realistic dimensions of the smart servicescape would require a grounded theory approach by observing users’ service experiences. Hence, to be utilized as an analytic framework of service experiences, this study adopts Service Blueprinting. Service Blueprinting, pioneered by Shostack (1984), is a diagrammatic method to profile how the process of service provision is understood in service design. Service Blueprinting plots all the key activities and their linkages involved in service delivery and visually separates frontstage/backstage interactions and physical evidence from service delivery to emphasize the perspective of customers (Patrício, Fisk, Cunha, & Constantine, 2011). As shown in Table 2, Bitner, Ostrom, and Morgan (2008) clarified the components of Service Blueprinting as customer actions, physical evidence, onstage touchpoints, backstage actions, and support processes. More recently, Patrício et al. (2011) proposed the Service Experience Blueprint, intergrating the design logics of Service Blueprinting and Activity Diagrams which are more appropriate to structure the (software) service system interface.

Based on two representative concepts in the literature, this study established an initial framework of the service experience blueprint comprised of the following elements:

- **Service encounters** are the main steps a customer takes to interact with an organization’s service, which parallel the customer actions.
- **Physical servicescape** in the literature (i.e., equipment, space, ambience, and design aspect) could correspond to the physical evidence that originally represents the touchpoints that customers interact with.
- **Frontstage interactions** are the visible actions between the user and the service provider that could be matched to onstage touchpoints; the line of interaction distinguishes frontstage interactions from the physical servicescape; the line of visibility separates frontstage interactions from the backstage actions.
- **Backstage actions** are the internal service provision mechanisms that are not visible to the customer but directly impact the customer experience.
- **Support processes** are originally the internal processes that indirectly impact the customer experience, such as interactions between the organization and partners or third-party suppliers. As this study will focus more on the interaction and relationship aspect, the support processes were substituted by the social servicescape of in-service/non-commercial relationships.

In this way, the service blueprint framework could be infused with the service experience viewpoint comprised of service encounters and the servicescape.

Research Methods

As previously mentioned, a grounded theory approach that observes users’ service experiences would be suitable for exploring the new and realistic dimensions of the smart servicescape. However, smart services, including the smart home services on which this study focuses, are not yet widespread in our normal life, and thus certain kinds of simulated smart home environments would be required. Instead, as a preliminary study, the researchers collected 20 user scenario movie clips from the website YouTube™, which were produced and uploaded officially by ICT corporations that have been developing and offering smart home services (e.g., Amazon, Google, LG, Naver, Samsung, and Philips).

The researchers first watched the movie clips to gain a general consensus about the level of smart home services. They then developed a representative user journey—namely, the series of interactions or service encounters—that embraced the various service experiences demonstrated in the movie clips. This user journey was specified into a general phase, more detailed action steps, and service encounters. For instance, “In the kitchen” phase consisted of action steps such as Select menu, Check ingredients, Purchase the ingredients, Look up the recipes, Cook, and so on. In terms of service encounters, Menu recommendation and Menu confirmation were the main interactions of “Select menu” action step. The action steps and service encounters were adjusted repeatedly while checking the reference movie clips. Next, the service experience blueprint framework established from the literature (Table 2) was adopted as an initial analytic framework. The observed content items from the reference movie clips were assigned according to the user journey, and the addition, combination, relocation, and relabeling of content and categories were repeated to improve the framework to make it more suitable for the smart servicescape.

Subsequently, a service experience blueprint of the smart home service, as displayed in Figure 1, has been developed. Accordingly, Figure 2 exhibits the final framework for the smart servicescape, as derived from the smart home service experience blueprint of Figure 1.
Figure 1. A service experience blueprint of the smart home service
Results and Discussion

During the qualitative analysis to elaborate a more explicable framework for the smart service experience, particularly for the smart servicescape, as shown in Figure 2, four modification points have emerged.

First, most parts of the equipment corresponded to smart devices, as smart services are mostly delivered through them, and thus the equipment was relabeled as Smart device. Furthermore, the Smart device was specified in device and interface; the device was categorized as controlling, sensing and monitoring, and actuating types; and the interface type was classified as visual, touch, voice, gesture, eye-gaze, and so on. Although the Smart device encompassed both the device and the interface elements, the line of interaction was positioned in-between separating them.

Second, though the data was not considered in a physical or social environment, it was a critical element in the process of the smart service experience, since real-time data collection and the continuous data exchange of intelligent objects are key characteristics of smart services. Therefore, Datascape was newly added as an independent dimension of the smart servicescape. In addition, input and output data were specified in terms of data content. Besides this, the internal database in which the customized data was accumulated, and the external database (e.g., big data) that the internal database refers to and communicates with,
were added to this *Datascape*. The line of visibility was located between the data content and the database, as the content of the input/output data could be perceptible to service users.

Third, *Connected scape* was also added as a separate category of the smart servicescape to explain the network infrastructure, which enables smooth data communication—namely, the smooth function of *Datascape*. In addition to the network infrastructure, cloud computing or connection with other devices such as N-screen were the example elements of *Connected scape* observed in the movie clips.

Finally, the design aspect, which was the component of the physical servicescape in the initial framework, revealed relatively less importance compared to other dimensions during the analysis, because the elements relevant to the device interface design could be classified as belonging to *Smart device*. If there is any non-device design element, it could be applicable to the space environment. Therefore, the design was located as a sub-dimension of *Space* such as layout and function.

The value of this framework for the smart servicescape can be identified in two aspects. First, this framework proposes new dimensions to reflect the characteristics of smart services that have not been identified in conventional servicescape frameworks, including the addition of *Datascape* and *Connected scape*, and the relabeling of equipment as *Smart device*. Second, this framework suggests the structure of the service experience blueprint based on the service blueprinting and infused with the perspective of the service experience, which consists of service encounters and the servicescape. Consequently, the particular dimensions of the smart servicescape are presented according to the structure of the service experience blueprint.

Nevertheless, several limitations have been observed in the framework for the smart servicescape. The demonstration of service blueprinting clearly distinguishes the range of physical evidence, visible frontstage interactions, and invisible backstage actions. However, smart services have the characteristic of real-time connectedness, and the data collection and communication among users, smart devices, and environments occur in a ubiquitous way. Consequently, the omnipresence of *Datascape* and *Connected scape* could influence and also be influenced by *Smart device*, *Space*, *Ambience*, or *Social scape*. For this reason, the borders of the line of interaction or the line of visibility might be ambiguous in reality. To improve this limitation, therefore, further research is currently underway to ameliorate this framework accurate enough to reflect the omnipresent nature of the smart servicescape and to expand the scope of smart service domains, including smart cars or smart health services.
Conclusion

The growth of smart services has been stimulated by the active innovation and development of IoT technology. Compared to the proliferation of smart services, academic research in terms of service experience and service design is still in the initiation. Particularly with regard to a service experience viewpoint, it would be indispensable to consider the context and environment of smart services—namely, the “smart servicescape,” as it could influence users’ whole experience. Here has occurred the research opportunity about what kind of different characteristics the smart servicescape would have compared to the conventional servicescape due to the convergence of online and offline connected environments.

With this background, the research aim of this study was to propose a framework for the smart servicescape by identifying new dimensions that would reflect the characteristics of smart services. First, literature on the conventional servicescape and on the service blueprinting were reviewed in order to establish an initial analytic framework of service experience blueprint. Next, twenty user-scenario movie clips on smart home services officially produced by ICT corporations were collected, were analyzed in a qualitative way through grounded theory, and were classified according to the analytic framework. During the qualitative analysis process, the framework structure was improved to make it more appropriate for the smart servicescape.

The framework for the smart servicescape, derived from the smart home service experience blueprint, exhibited four differentiated points: (1) Smart device was positioned as a separate dimension and specified in device and interface; (2)Datascape was newly added to reflect the key characteristics of smart services (i.e., real-time data collection and the continuous data exchange of intelligent objects); (3)Connected scape was also added to explain the network infrastructure, which enables the smooth function of Datascape; and (4) design aspect was divided into the sub-properties of Smart device and Space. The values of this framework can be identified in two aspects: (1) by identifying new dimensions to reflect the characteristics of smart services; and (2) by suggesting the structure of the service experience blueprint infused with the perspective of service experience, which consists of service encounters and the servicescape.

Bio Fashion Design: A Study on Design Strategy for Sustainable Production Line through DIY Bio Experiment

Kazuya Kawasaki, Keio University Graduate School of Media and Governance, Tokyo, Japan, kkzy@sfc.keio.ac.jp

Dr. Daijiro Mizuno PhD RCA, Keio University, Tokyo, Japan, daijirom@sfc.keio.ac.jp

Abstract

There is a growing need for sustainable fashion since the 2010s. As artists and designers explore the potential use of innovative materials developed by synthetic biology and DIY bio-hacking (Myers, 2010), recent practice-led research in fashion design aims at building the better relationship between ecological sustainability and biotechnology to cope with the limited resources available on the earth (Fletcher, 2008). Based on this issue on the material sustainability, this practice-led research analyzes the current production processes of the fashion industry to propose possible solutions by incorporating emerging biotechnology and fashion design in the context of sustainable design. As the methodology, the authors adopt two processes to make bio-garment. First, the experiment of DIY bio has been conducted for culturing ecological bio-material SCOBY (symbiotic colony of bacteria and yeast) that produces bacterial cellulose. The material has similar properties to leather. Second, designing the garment through 3D modeling has been tackled because we aim to make the bio-materials grow onto a 3D printed mold as ‘zero waste method’ (Rissanen; Mcquillan, 2016), which can eliminate textile waste at the design stage. By the application of biological materials in the process of dressmaking, this practice-led research has been analyzing the production line of the fashion industry and trying to propose sustainable solutions. Also the research aims to combine emerging biotechnology and sustainable fashion in order to establish the design process as an alternative design process to the polluting industry.

Keywords: Fashion Design, Sustainable Fashion, Bio Design, Wearable Technology, Research Through Design and Design Strategy
Literature Review

Ever since theoretical physicist Freeman Dyson said “The twentieth century was the century of physics and the twenty first century will be the century of biology” in an essay “Our Biotech Future” in the New York Review, it is believed that biology should give an enormous impact on its environmental consequences, its ethical implications, and its effects on human welfare at the age of the coming century (Dyson, 2007). With the help of exploration and research in the field of wearable technology particularly in the 2010s, the fusion between fashion and biotechnology is about to happen (Ginsberg, 2014). The most developed area of integration of biological processes is Material Science. In the research on sustainable materials, designers and engineers have begun to look at the metabolic processes of microorganisms as a way to synthesize natural composites. For instance, Japanese company “Spiber” is developing the synthetic yarn “QMONOS”, a yarn made by manipulating fibroin. Fibroin has environmentally sustainable characteristics and can be spun into strong and flexible yarn.

Sustainability has become a growing issue in the field of fashion design in the late 2000s and early 2010s. The commercial fashion industry highly relies on mass production and mass consumption, and the resulting accumulation of textile waste has become the root of many serious environmental problems. In the context of sustainability, this study aims to speculate an alternative sustainable form of fashion and invert the system of the current fashion industry (Fletcher, 2007). The paper “Emerging issues in our global environment” published by the United Nations in 2011 states that especially in developed nations, the number of serious environmental problems is increasing, and the world population is estimated to exceed 9.6 billion in 2050 (UN, 2011). Population growth will obviously increase human energy consumption and would also impact the textiles and garment industries. Indeed, the global demand for garments continues to rise—the fabric consumption in 2012 was 78.88 million tons. This is around a 40 percent increase compared to the fabric consumption in 2003, and consumption is expected to continue growing. Synthetic fiber consumption was 50.14 million tons and cotton fiber consumption was 23.46 million tons in 2012. According to the World Apparel Fiber Consumption Survey by FAO (Food and Agriculture Organization of the United Nations), the sum of the world’s fiber consumption has been continuously growing from 38.99 million tons in 1992 to 69.70 million tons in 2010 (FAO, 2012).

Based on the background above, this practice-led research aims to speculate more sustainable garment design processes by examining differing stages in the manufacturing of sustainable bio fashion as a single design research project: material development and fashion pattern cutting.

The authors have focused on development of alternative pattern cutting techniques to effectively use the material to shape three-dimensional garments while minimizing fabric waste as remnants. Designers can design garments without any fabric waste using the method of “Zero Waste Fashion” (Rissanen, 2015), however, Rissanen’s proposed techniques is primarily for woven fabrics.

However, a metabolic system of new bio-materials enables us to design a more organic fabric through cooperation with digital fabrication technology such as 3D modeling tool. Hence undertaken research therefore aims to improve the conventional pattern cutting techniques.
Research Methods

The authors argue that the field of sustainable fashion needs to deal with 1) material, 2) process of production, 3) distribution, 4) use of garments, and 5) disposal (Fletcher, 2008). According to Fletcher, the current fashion industry consists of many stakeholders, and it requires holistic solutions for this wicked problem. If designers of the sustainable bio fashion cope with the complex socio-technical issues, they have to challenge not just a single issue but to speculate and implement the holistic manufacturing processes of the fashion industry from the broad spectrum. To achieve this end, this practice-led research aims to speculate more sustainable garment manufacturing processes by examining differing stages in the manufacturing of sustainable bio fashion as a single design research project. This paper specially looks at the following design stages: 1) material development using bacteria and yeast. 2) pattern cutting based on digital fabrication technology. 3) dyeing using living pigments.

Figure 1: The production Strategy of Sustainable Fashion
Discussion

Experiment 1: Incubation of Bio-cellulose

The authors set SCOBY (Symbiotic Colony of Bacteria and Yeast) as their object of study, practically conducted incubation experiments, recorded their process, and collected their data. The process of research is below:

1. SCOBY is a colony of bacteria that consists of Zygosaccharomyces sp, a yeast, and Acetobacter xylinum, an acetic acid bacteria. SCOBY produces celluloses by the principles of fomentation and a sheet of cellulose is layered to expand its volume and capacity.

2. Construction of Incubation Environment: The incubation environment is mainly conducted at home of the author and we made an incubator and a medium. A plastic box was used as the incubator and its size was 800*600*200mm. Medium was made from organic vinegar water, sugar, and green tea.

3. Record of Incubation Experiments: The experiment of incubation was done for 14 days at one room of an apartment in Tokyo. We recorded the temperature, moisture, and water temperature by an infrared thermometer. Also, we noted the process of this experiment.

4. Washing and Drying Materials: As it has been 12 days since the experiment started, the thickness of the material reached 25mm. After that, the material was taken off from the tank and we washed and dried it. After the finish of washing, the material was dried for
Experiment 2: 2.5D pattern cutting

The process of fashion design is mainly premised on pattern cutting for two dimensions except knit and leather. However, a metabolic system of new bio-materials enable us to design more organic fabric. Based on that techniques, the current garments production process that we all are taking for granted today will radically change.

This practice improves the conventional technique of pattern cutting and invents an alternative design process. This research uses a material called SCOBY as a case-study. It would be one of the interesting features of SCOBY that you could control its shape during the cultivation process by constructing its environment or situation. In other words, if you incubate SCOBY on a curved surface of a tank, SCOBY will produces textile along the curved shape. It would be one of the interesting features of SCOBY that you could control its shape during the cultivation process by constructing its environment or situation.

These processes in which SCOBY produces three dimensional fabric have a high affinity with digital fabrication. Also, following this method, designers can design garments without any fabric waste. Then, the authors used a large-scale tectonic 3D-printer that can generate human-scale objects, and created a mold in order to model bio-materials. On the mold, the authors incubated the material. The detailed process of this practice is below:

1. Production of the sleeve pattern: The authors made the fashion pattern impregnated with calcinated plaster.
Figure 4: Physical Scanning with calcinated plaster

Figure 5: Physical Scanning tailored suit fashion pattern
2. Scanning of the pattern with a 3D scanner: The authors scanned, digitized the pattern, and edited the data for printing it with a 3D printer and CNC milling machine.
3. Printing the edited data: The authors 3D printed the sleeve data with the 3D printer and CNC machine, which is specialized for large scaled data, especially for architects.

Figure 8: Milling the pattern with CNC Milling machine
(Shopbot)

Figure 9: 2.5 dimensional fashion pattern
4. Molding the biomaterials: The authors dried the biomaterials out on the catted pattern, and molded the curved surface without straightening materials.

![Molding test](image)

Figure 10: Molding test

5. Sewing: After drying, the authors cut and sewed the material.

![Molding test output](image)

Figure 10: Molding test output
In order to create carve shapes in the design phase, the conventional 2D pattern cutting is based on darts which cause many textile wastes. On the other hands, the 2.5D method enables us to change darts into molds to omit textile emissions. The scale of mold depends on available dimensions of digital fabrication machines. Then, the authors separate the data into components of garments: like the bust, waist, and hip. It suggests a use of 2D straight pattern and 3D mold in combination. The authors developed parts of pattern of 3D carve shape like shoulder, bust and hip with digital fabrication tools: CNC Milling Machine (Shopbot) and 3D printer. The combination of 3d and 2D fashion pattern prototypes have it both ways of the zero waste method and creation for carve shape.

Experiment 3:

To create a comprehensive sustainable production line, it is necessary to develop a finishing process that includes dyeing in relation to the previous research. This is an experiment to develop dyes that uses bacteria with color-pigments. Although there are various ways in which to use the principles of fermentation such as indigo dye, this research aims to invent a new dyeing method that can be applied to bacteria.

1. Incubation of Janthinobacterium lividum : the authors incubated a bacteria provided by the Waag Society, Janthinobacterium lividum, and confirmed microbial growth.

2. Construction of Incubation Environment : The authors conducted the experiments at a laboratory with a clean bench, an autoclave, and an incubator. The incubation was done in a sterilized environment in the clean bench. Then, utensils were treated with the autoclave.

Figure 11: Incubation Environment
3. Record of Incubation Experiments: The bacteria was incubated in the incubator where the temperature was controlled at 30°F.

4. Experiments of Textile Dyes: The authors cut cotton, hemp, and silk fiber into 80mm squares. Also, we transfuse N/A medium into the fabric, and incubated on the medium.

![Figure 12: Textile Dyes](image)

**Conclusion**

So far, the research has revealed the possibilities of the 3D design process for bio-material SCOBY as sustainable material. However, several challenges still remain. For examples, the study of waterproof of the materials and the development of the garment design methodology. The ultimate goal of the research is speculation on an alternative production line and design strategy toward the future of sustainable fashion.

Author Biography

Kazuya Kawasaki
Born in 1991, is a fashion designer who is trying to create a new era of “speculative fashion”. He designs fashion works that speculate about an alternative fashion industry in order to explore the possibility of fusion between fashion design and emerging technology such as biotechnology and wearable technology. Kazuya’s works have been presented at Are Electronica (Linz, 2017), National Museum of Scotland (Edinburgh, 2017), Hong Kong Design Institute (2016, Hong Kong), Design Indaba (2016, Cape town), and AXIS gallery (Tokyo, 2015). He is working as a textile researcher at Poiesis Labs founded by Shiho Fukuhara.

Dr. Daijiro Mizuno PhD RCA
Born in Tokyo in 1979, completed an MA and a PhD in Fashion Design at Royal College of Art. Daijiro’s research projects speculate about how design can make a positive impact on our society. Daijiro is currently working as an Associate Professor at Keio University Faculty of Environment and Information Studies while working as a freelance design researcher. Daijiro also works as a co- editor in chief of fashion design critique periodical, Vanitas.
Challenges and Lessons: Embracing Design Thinking Practices for Website Innovation in South Korea
Yujin Kim, Kongju National Univ., Gongju, South Korea
baramein@gmail.com

Abstract

This research aims to investigate how Korean digital agencies practice design thinking for their website innovation. Based on a literature review on the design-thinking-driven web development process, multiple case studies of award-winning website projects were undertook. Through analyses of these cases, the following challenges and lessons were disclosed: (1) challenges – building a long-term, playful partnership with clients, leveraging decision-making executives’ design thinking awareness, and coping with limited resources (design thinking practitioners, budgets, and schedules) and (2) lessons – cross-functional collaboration, agile mobile-first development process, powerful visual storytelling, and compelling UX strategies and UI guidelines. Moreover, distinct approaches of design thinking practices were identified according to two website types: a brand promotion website – killer branding content-driven approach, and a service channel website – better UI/UX-driven approach.

Keywords: design thinking, design strategy, digital marketing, digital design agencies, website innovation, UI/UX design

The proliferation of digital technologies has diversified digital marketing platforms from web to mobile to social media. Among these platforms, the website is still an important starting point and the centerpiece for digital marketing because its content and operation can be fully controlled by a company, unlike social media sites. In particular, a well-designed website with high usability positively influences visitor retention and purchasing behaviors (Garett et al., 2016). Therefore, companies have paid more attention to how to build innovative websites that implement compelling branding or marketing strategies, while orchestrating other marketing channels.

Along with the companies’ increasing interests in developing competitive websites, leading digital (design) agencies have broadened their expertise and service areas from building websites to identifying new digital marketing strategies and user experiences by adapting design thinking practices, once used primarily in product design (Groysberg & Slind, 2011; Kim et al., 2012). Conspicuously, Korean digital agencies have recently made great efforts to actively incorporate design thinking practices into their website development process; however, many of them are still struggling with the application of these practices.

In this vein, the present study aims to investigate the strategic deployment of design thinking to the web development process in Korea. To reach this aim, based on the theoretical framework of a design-thinking-driven web development process, case studies of four award-winning website projects were performed.
Literature Review: Design-thinking-driven Web Development Process

Over the past decade, the volume of practical writing on the topic of “design thinking” has dramatically increased. In popular management/business books and magazines, design thinking has been described as “a novel problem-solving methodology well suited to the often-cited challenges business organization face in encouraging innovation and growth (Liedtka, 2014, p.1).” As a popularized management version of translating designerly thinking, design thinking is heralded as a way to make managers think more creatively and use designer’s specific methods (Johansson-Sköldberg et al., 2013). In this designerly thinking perspective, Shapira et al. (2017) characterized the term “design thinking” by the following themes based on a literature review: human-centeredness, research-based, awareness of the surrounding context, collaboration, optimism, non-linearity, and experimentation.

Moreover, for driving innovation outcomes, a design thinking process prioritizes deep empathy for end-user desires, needs, and challenges to define the right problem, as well as iterative prototyping and testing phases to find appropriate solution. This design thinking process has been illustrated in various ways such as the following popular frameworks: (1) IDEO’s Human-Centered Design (HCD) process: inspiration, ideation, and implementation (IDEO.org, 2015); (2) Stanford d.school Design Thinking process: empathize, define, ideate, prototype, and test (Plattner, 2010); (3) the British Design Council’s Double Diamond: discover, define, develop, and deliver (Design Council, 2015). Among them, the Double Diamond model most clearly visualizes the iterative cycle between confirming the problem definition and creating its solutions in two diamond shapes. Consequently, the present research sticks to the Double Diamond in order to theoretically incorporate design thinking practices into the general web development process that consists of web planning and design/development stages, as shown in Figure 1.

Figure 1: Design-thinking-driven web development process
Research Methodology: Case Studies

Given the complexity and dynamics of the real website development process, multiple case studies were carried out while increasing the credibility of the results. Four award-winning website projects were selected for investigating how Korean digital agencies practice design thinking for their website innovation. These projects received the following awards from the 2016 Web Award Korea\(^1\), which has become the most prominent domestic web competition: Amorepacific global website (the Grand Prize), Chungjungone brand website (the Brand Innovation Prize), SK Telecom T-world service website (the UI/UX Innovation Prize), and KT Olleh shop website (the Marketing Innovation Prize). The results of the case studies were drawn from in-depth interviews with key people, as well as published and unpublished information.

Results

Amorepacific Global Website\(^2\)

Amorepacific Corp. is the largest beauty company of South Korea, operating over 30 beauty, healthcare, and personal care brands including Hera, Sulwhasoo, Laneige, Etude House, Lolita Lempicka, Happy Bath, Osulloc, and others. It has become the 14\(^{th}\) largest cosmetics company and ranked #16 in the 2017 World’s Most Innovative Companies by Forbes (debuting at #28 in 2015). Moreover, the company garnered more global appeal since inventing and launching its “cushion compact\(^3\),” which revolutionized make-up routines by reducing the make-up steps and time for women. Along with these compacts’ huge success in the domestic and overseas marketplaces, Amorepacific has made further efforts toward global expansion into the Chinese, the Southeast Asian, and even the U.S. markets. In these circumstances, the company requested renovation of its global website from a Korean digital design agency called Iropke, which has undertaken a variety of internal digital marketing projects while maintaining long-term partnerships for several years.

In general, most Korean companies begin with developing their official website written in Korean and then launch their multilingual websites by translating its content in different languages. With Iropke, however, Amorepacific built its global website in a completely different way. They created the global website (written in English) before renovating the domestic official website. In order to establish the global content strategy targeting North American customers, the agency worked with staff in its New York office during the first half of the project period. Based on meaningful insights drawn from a variety of user research with American customers, the project team created new brand communication contents (i.e. texts, graphics, photos, and videos), solely for the global website (Figure 2a). They also used trendy UI patterns suited to the global users’ website surfing behaviors (e.g. drop-down menus showing their sub-menus at a glance). In the development process, the agency focused on worldwide fast access to the relevant brand contents via diverse devices.

---

\(^1\) Since its establishment in 2003 as the first domestic web award competition, the Web Award Korea has annually announced the best websites through online and offline evaluation processes undertaken by over 3,000 professionals in marketing, design, and development fields. Its award-winning websites are evaluated by the following six criteria: visual design, UI design, technology, content, service, and marketing.

\(^2\) http://www.amorepacific.com/int/en

\(^3\) Cushion compacts are built with specially-designed urethane foam that preserves make-up liquid comprised of foundation, sunscreen and skin care formula. Since its introduction in 2008, more than 70 million cushion compacts have been sold.
and browsers with the implementation of mobile-first design, responsive web UI/UX design, intuitive navigation planning, a Content Delivery Network (CDN) server, and a Search Engine Optimization (SEO) process. After the successful launching of its global website, whose UVs, PVs, and mobile access rates increased noticeably, the company has been working on building other language websites including the Korean and Chinese versions under their own respective brand communication strategies.

Figures 2: (a) The landing page of the Amorepacific global website, using a high-quality video background that tells its brand stories (e.g. R&D innovation, heritage ingredients, and sub-brands), and (b) The trendy card-based layout design for displaying a variety of bite-sized brand contents (text, image, video, and others)

Chungjungone Brand Website

Founded in 1956, Daesang Corp. has become the leading consumer food producer in Korea and has manufacturing subsidiaries around the world, with annual sales revenue of 2 billion dollars. Since 1996, its diverse foods have been produced under its flagship food brand Chungjungone, which means “clean and good care of the nature.” Chungjungone has promoted its brand through various offline events for invigorating active housewife communities as well as online marketing activities from Cyworld mini homepages, Naver cafés and blog, to its own community website. After its brand logo renewal for delivering food specialist images in 2014, Chungjungone ramped up its brand experience platforms including online marketing activities (social media and foodcasts), offline events (cooking classes), and development of new cooking tools. As its brand experience contents have been more diverse and widespread, Chungjungone decided to build a new brand website as its own digital hub for integrating and managing offline and online brand experiences systemically and continuously. First of all, Chungjungone undertook user research for encompassing different target groups beyond housewives as well as discovering relevant brand experience contents. Consequently, as shown in Figure 2b, a card-based responsive website was developed as the Chungjungone’s core digital brand community platform. Along with continuous creation of high-quality brand contents (e.g. Foodcast videos and Food knowhow tips), this website stresses interconnecting with its other social media contents such as Facebook, Instagram, Naver blog, and Kakao. Due to these efforts, its UVs and PVs have been increasing along with expanding its loyal customer base.

4 http://www.chungjungone.com
SK Telecom T-world Service Website

As the largest, domestic wireless telecommunications operator, SK Telecom had managed numerous service websites individually. In 2016, therefore, SK Telecom built a consortium with several firms specialized in research, design, and development to integrate its core customer service touch channels into the T-world website. Due to more than 100 menus and 1000 products of SK Telecom, this project took more than two years (one year for establishing UI/UX strategies and one year for developing the website). Through the discover stage, its project team conducted a variety of research including user research, channel requirement analysis, competitive analysis, royalty roof analysis, and others. Based on the research results, they defined systematic UI/UX strategies and guidelines for a meaningful user journey throughout all of the webpages. Next, the project team translated these strategies into systematic web style guides (Figure 4a), focusing on the following aspects: a design language for better information visualization, interactive chat-robot communication, and more personalized contents/services. This T-world website enables SK Telecom to provide more meaningful experiences to customers according to continuous monitoring their needs and preferences, and to deliver consistent service experiences across diverse user touch-points.

KT Olleh Shop Website

KT Corp. (formerly, Korea Telecom) is South Korea's largest telephone company, and it has expanded its business into the wireless market since its 2009 merger with

---

5 http://www.tworld.co.kr
6 http://shop.olleh.com
KTF, one of the previous telecommunication companies. In 2011, KT launched a unified brand "Olleh" for both fixed-line and cellular broadband services. In particular, KT runs the Olleh shop, one of the largest domestic online shopping malls specialized in telecommunication products and services. In order to increase its sales volume and enhance users’ shopping experiences, KT has worked on its renewal project recently. In this project, KT discovered users’ pain points though a wide range of UI/UX studies including heuristic evaluation, stakeholder interview, usability testing, and user gang survey. Based on these findings, they were able to improve its user experiences, focusing on user-centered navigation structures, user-friendly ordering processes, and customized marketing contents or services (Figure 3b). In addition, strategic marketing and sales techniques were suggested by external UX consulting firms. Compared to KT’s practical and stable brand images, its new brand identity (i.e. new, active, and fun) was also established for providing more pleasant shopping experiences, and this new brand image was translated it into the relevant and emotional visuals on the website. Since its renewal, its online purchase conversion rate has been increasing gradually.

Discussion and Conclusion

Through the case studies above, the present study proved that aesthetic visualization or technological advancement is not enough to create compelling digital marketing websites. In order to boost user engagement on websites, the design thinking approach focusing on up-front user research or usability testing is not an option, but a prerequisite; however, it was also discovered that the current digital design agencies have been facing numerous challenges in adopting the design-thinking-driven web development process: (1) playing initiative or participative roles in the strategic web development process while building long-term, playful partnerships with their clients, (2) leveraging design thinking awareness of client-side executives who make influential decisions on financial or managerial supports for their web projects; and (3) coping with limited recourses (e.g. hiring prominent design thinking practitioners, securing enough research budgets or facilities, and setting effective project schedules).

On the other hand, the common key success factors of the four award-winning web projects were identified: (1) cross-functional collaboration among planners, designer, and developers throughout the whole iterative development process; (2) agile mobile-first development approach with the priority on responsive web design, in accordance with the dramatic proliferation of mobile users; (3) powerful visual storytelling about brands or products/services, while following the current web design trends (e.g. flat design, cinemagraphs, micro-interactions, hero images, bigger typographies, smaller color palettes, spotted data, shorter user flows, etc.); and (4) compelling UX strategies and UI guidelines for better user journeys across webpages.

Moreover, two distinct approaches of design thinking practices were identified according to the following website types: a brand promotion website (e.g. Amorepacific and Chungjungone) – killer branding content-driven approach, and a service channel website (e.g. T-world and Olleh shop) – better UI/UX-driven approach. In addition, considering their project schedules and scopes, this research mapped out their web development practices into the aforementioned design thinking-driven web development framework. As shown in Figure 4, their development processes were illustrated while dividing their planning and design/development
stages at the moment when their strategies were mapped out (e.g. Global brand communication strategies for the Amorepacific global website). Noticeably, due to growing bite-seized pieces of its brand community contents, the Chungjungone project allotted more time for the design/development stage, compared with the fixed brand promotion contents of the Amorepacific global website. Furthermore, in order to bind diverse online user touch-points into the T-world website, SKT made more efforts to consistently deploy its service UI/UX strategies and guidelines across different service websites and numerous webpages. On the other hand, through incorporating a wide range of usability testing methods into the planning stage, the KT Olleh project team could come up with divergent ideas about users’ pain-points and convergent insights for better shopping experiences.

Finally, this study revealed that the impact of the design thinking approach on website innovation through the examination of both theoretical works and actual management practices of the leading Korean web projects. Some extended research could improve the practical application of the research results by including international web projects. It is hoped that this research will provide digital agencies with hands-on and practical knowledge in integrating design thinking practices into the new website development process.

Abstract

Design processes are so complex that it is not easy to remember, reflect and record in detail after the actual processes are over. This paper proposes a notation to depict a design process as a whole while keeping its original complexity in terms of visual and structural aspects. The notion affords two types of structures to represent design processes, through activity units, a series of actions of the same kind, and design elements including ideas, prototypes and theories emerged, created, and applied during the design process. We use a design process of an actual design workshop as a case to derive the notation while using the online presentation tool “Prezi” as an interaction framework. We then investigated the depicted design process by re-experiencing the process as a first-person engagement using the designed notation. Prezi’s animation mode allowed us designate a sequence along which viewers can experience the design process by zooming in some activity units and design elements, and its presentation mode allows us to look back the design process from the start to the end by following activity units arranged in the temporal order. Following the transitions among some design elements allows us to focus on essential objects in the design process. The depicted process illustrate that the two structures of activity units and design elements are not corresponding to but independent of each other.

Keywords: design process, depiction, complexity, empirical study

1. Introduction

Design processes are quite complex and chaotic. We are aware from our own design experience that a design discussion sometimes goes to divergence even though the designer wants it to converge, that a quintessential idea emerges unexpectedly without paying much attention on the analysis of the situation, and that multiple ways of thinking proceed simultaneously in the designer's mind. Existing design research has presented two approaches to analyze complex design processes. The one approach is to segment a design process into a series of parts along the timeline. Baker and Hoek (2010) expresses the design processes of workshops in a way similar to a task scheduling chart by categorizing subjects of discussion the designers addressed, and how designers attended to the subjects. One of our previous studies has shown the design processes of twenty-seven workshops in the form of series of time-stamped self-reported activities, which lasted for three days in parallel on different topics (Kita et al. 2016). The other approach is to focus on concepts and ideas emerged during a design process and to plot them at the points of time when they arise along the timeline. Goldschmidt (1990) proposed a concept called design move, which is defined as “a step, an act, or an operation, which transforms the design situation.” Goldschmidt developed a notation called linkography where such design moves and their relationships are visually represented. Design practice generally uses a widely accepted views of a design process, such as analysis-
and-synthesis, divergence-and-convergence, or the Plan-Do-Check-Action cycle. A design firm IDEO proposes a cycle of emphasize, define, ideate, prototype and test. These process models are mainly to understand and guide a design process by dividing it into several phases along the timeline.

We argue that such existing approaches on depicting a design process primarily aim at simplifying what had been actually happening during a design process in order to analyze and better comprehend the process. As such, elements used in those depicted process models are often abstracted and sometimes oversimplified, resulting in the lack of details of some aspects of a design process. Missing details of a design process make it impossible for designers to reflect on some aspects of the process, and for non-members of the design project to understand what happened in some moments during the process. Missing details of a design process may matter in different contexts. It is not possible to know a priori which details would matter later in the time. A seemingly trivial activity at the time of the actual design project might lead to a significant consequence if the project is reflected back years later.

The research presented in this paper is not to suggest yet another design process notation to simplify the process. Rather, we are interested in developing a notation, which would allow us to know what actually happened as a design activity in a variety of details on demand. Such a notation would make it possible for us to look back and re-experience the design process as a whole as needs and interests emerge.

The second aspect of our goal is to investigate the depicted design process by re-experiencing the process as a first-person engagement using the notation. Studying the user experience of a depicted process would help us examine whether the representation of the design process based on the notation actually embodies the design process as it was. It would also help us analyze how the two types of structures, activities and elements, correspond to design process re-experiences.

2. The Approach

The goal of this project is twofold. First, we are interested in developing a notation to depict an actual design process as a whole while keeping its original complexity in terms of visual and structural aspects. We use a design process captured during an actual design workshop to derive such a notation. We propose to use two types of structures to represent design processes, consisting of what focuses on design activities, and what focuses on design elements such as ideas, prototypes and theories emerged, created, and applied during the design process.

The second aspect of our goal is to investigate the depicted design process by re-experiencing the process as a first-person engagement using the notation. Studying the user experience of a depicted process would help us examine whether the representation of the design process based on the notation actually embodies the design process as it was. It would also help us analyze how the two types of structures, activities and elements, correspond to design process re-experiences. We use a free online presentation tool “Prezi” (https://prezi.com/) as an interaction framework to develop a notation for a design process. Prezi allows us to arrange words, diagrams and pictures at various levels of granularity on a vast canvas. We can also set an animation mode on objects on the Prezi canvas to change viewpoints by zooming in elements along a temporal sequence designated by the user. Such features of Prezi make it easy for us to interact with and experience the representations produced as a depiction of a process by viewing it both in its entirety and in details.
3. A Sampled Design Project

We have sampled and studied in detail a design project in order to design the notation for a design process. The sampled project was a workshop titled “about Jimen.” The meaning of a Japanese word “Jimen” is roughly equivalent to ground in English, but not exactly the same. The workshop organizers, which included one of the authors of this paper, chose this title so that the word implies more than a physical ground or surface of ground, such as geography, a land lot, or the earth. The goal of the workshop “about Jimen” was to produce ideas to make and turn our city into more attractive place for residents and visitors by observing existing “Jimen,” and freely imagining an ideal form on it. This was one of the 37 workshops conducted during “Kyoto University Summer Design School 2016,” an event held in September 2016 for three consecutive days (http://www.design.kyoto-u.ac.jp/sds2016/). The design workshop was organized by the first author of this paper (serving as a workshop director) and two other faculty members. Six members consisting of university students and office workers participated in the workshop.

The “about Jimen” workshop was quite challenging both for the participants as well as for the organizers. Focusing on an abstract object to design, the workshop made each member to extensively collaborate with others who have different backgrounds. Because of the ample complexity inherent to the arrangements of the workshop, we have decided to use the data from

![Figure 1: A depicted design process of the "about Jimen" workshop](image)

(Note: The annotations in red and green are later added and are corresponding to the areas in Figure 3 and Figure 4.)
this workshop as a case data to derive a notation for depicting a design process for our goal. When the workshop was over, the first author looked back the workshop and started representing its process. We first sketched out the process roughly by hand, and rectified it by using Prezi. The notation was not originally prepared before the depiction but gradually and incrementally evolved through the externalization process. Figure 1 shows the depicted design process of “about Jimen” using the developed notation, in which the time flows from left to right. The original Prezi data of this depiction is available at the website (https://tr.im/sds2016process).

Note that the designed notation is not limited to the use by those who are actually engaged in the design process: external observers may also use the notation to represent the design process.

4. Designed Notation

Figure 2 shows the legend of the notation developed during the above step. The notation affords two types of structures.

The first type of structure is *activity units*, where the process time is divided into a nested structure. An activity unit corresponds to a series of actions of the same kind, such as fieldwork, presentation preparation, or an organizers’ briefing. Each activity unit is presented with a square bracket which encloses the period of time of the activity in the timeline. The notation defines three relationships among units. The *sequential relationship* is presented by arranging two or more units horizontally. It expresses activities conducted in a consecutive manner along the timeline. The *concurrent relationship* is represented by putting two or more activity units vertically. It expresses such situations as team members separate into some groups and conduct different activities in parallel. The *inclusive relationship* is represented by nesting brackets. It expresses activity units in a hierarchic structure.

The second type of structure is *design elements*. Design elements represent concepts or objects...
which are produced, emerged or mentioned during a design process, such as ideas, prototypes, photos, analysis results, particular theories, or methods. Design elements are represented by texts with signs. If a design element is a visual object (i.e., a picture or a sketch), it is presented by arranging the element on Prezi canvas. When the design element is restated, reused, refined or changed later, or when a cause-and-effect relationship arises between elements, an arrow is used to connect the point of time on which the original element arises and the point of time on which it is restated, reused, refined, changed or effected. Thus, such an arrow represents the transition among connected design elements. Different types of design elements are displayed in different signs as shown in Figure 2. Activity units may also be treated as ones of design elements because we can often find cause and effect relationship among activity units or between activity unit and design element.

5. Experiencing the Notation

Prezi’s animation mode allows us designate a sequence along which viewers can experience the design process by zooming in some activity units and design elements. We designated two types of animation corresponding to two structures. The first type of animation is to follow activity units in the temporal order. Figure 3 shows a part of sequence of designated animation. This type of animation follows activity units in a sequential relationship. When some activity units are in inclusion relationship, the animation displays from a higher activity unit in the hierarchic structure to lower ones. When the members separate to groups and a concurrent relationship between activity units arises, the animation first displays the activities from one group then those of another. When pictures, sketches or thoughts of the writer are arranged on the canvas, animation zooms in such elements to make it easier for viewers to read the contents.

![Figure 3](image)

我们可以从始至终按照活动单位顺序回顾设计过程。这种体验使我们能够追踪过程中发生的事情。包容性关系不仅帮助我们按照一个一个活动单位的顺序进行，而且在活动单位之间并行浏览。我们可以浏览所有不同的在平行中通过并发关系。

The second type of animation is to follow the transitions of design elements. Figure 4 shows a part of the animation of this type. It starts at the point of time on which a design element arises

![Figure 4](image)
and flies along the arrow to the next point of time on which the element transits. When the animation reaches to a final transition point of a design element, it goes back to the start of the timeline and follows the transition of other design element.

Following the transitions of design elements allows us to focus on the key objects in the design process. This type of experience helps us to know what had been important in the design process.

By using animation, we depicted the design process not only as a static figure, but also as a dynamic presentation which makes the process to be re-experienced sequentially by the viewers. Animation works for designers who engaged in the process to profoundly reflect on the process and also for non-members of the design project to better grasp the process.

6. Discussion

6.1. The Role of the Two Structures

Design elements may be left out and not attended to for a long time in the process. For example in “about Jimen,” some contents of the lecture on Day 1’s morning effected on the ideation phase in the latter half of Day 2. A picture taken in Day 1’s fieldwork gave inspiration to a participant in Day 2. In contrast, activity units connected directory with a sequential relationship often shared little from the aspect of design elements. Though participants summed up examinations in the fieldwork on Day 1, the summary, which was a kind of design element, did not have explicit effects on the following activity because it was a lecture on how to do sketching.

The creation of each design element is inevitably situated during an activity unit. How designers think and what kind of design element emerges depend on the activity unit in which the design element is born.

Two structures of activity units and design elements are not corresponding but independent of each other. We have found that this might be the reason why design processes are often found complex.

6.2. Planning a Design Process based on the Notation

The notation may also be useful for planning design activities. Designers may sketch out how to proceed a design process in advance by using the notation. For effective planning of the design process, it would be necessary to prospect what kind of structure of activity units and design...
elements would be suitable. This is one of the future agenda for our research.

Designing Supportive Technology for Teaching Assistants Monitoring Collaboration

LuEttaMae Lawrence, University of Illinois Urbana-Champaign, Champaign, USA, llawarnc2@illinois.edu
Emma Mercier, University of Illinois Urbana-Champaign, Champaign, USA, mercier@illinois.edu

Abstract

Decisions made by user interface designers play an influential role in how people interact with software, this is especially true when it comes to the creation of tools to support teaching. As technology continues to play a more prominent role in schools, it poses an important question about how the design of learning tools influence what teachers do in classrooms. Data analytics is one opportunity technology offers for teachers to foster collaboration in student groups. Data analytics have the potential to provide teachers with a live view of what students are doing when using technology, which research shows is challenging to implement in classrooms. This paper focuses on the process to design a tool that assists engineering discussion session teacher assistants (TAs) to monitor collaboration within groups. We report on findings from interviews with TAs on what they anticipate they would need in order to support group work, and discuss how their responses influenced the design of this tool.

Engineering; Dashboard design; Teaching; Collaborative Learning

Introduction

The design of technology for learning is often influenced by current trends in design, rather than by the theory and research about how students learn and what teachers need to support them (Hirsh-Pasek et al., 2015). Research indicates there are a range of opportunities for technology to monitor and support collaboration (e.g. Dillenbourg & Evans, 2011; Roschelle & Pea, 2002), although, there is little research into how the technology can be designed to provide insight for teachers into collaborative processes. Including teachers in the design process can increase their comfort level when using the technology, which can lead to more successful implementation in the classroom (Cviko, McKenney, & Voogt, 2014). This process, user centered design, has become more prominent in the social sciences in the last few years; by placing the user in the design process there is a greater chance that their needs will be met and the design will be successful (Sanders, 2002). This study includes teacher assistants (TAs) in the design of an orchestration tool, which will be used in their classrooms in future semesters.

In this paper, we describe interviews conducted with TAs, as we are in the process of developing orchestration tools to be used in the classes that they teach. The tools allow TAs to monitor collaboration in an engineering discussion session, and provide insight to them for how to intervene in the groups. This paper builds on earlier work, which found that TAs rarely provided anything more than content-based support to groups, and had little understanding of what successful collaborations would look like or how to intervene when groups struggled
These findings indicate a need to assist TAs using collaboration in their classroom, with one possibility being to provide them with live insight into the groups’ processes to help them understand what is going on in the groups, and how they might intervene if groups were encountering interaction difficulties. In this paper, we focus on the process of designing a TA tool that provides insight into group processes during class activities.

**Literature Review**

One important potential of technology is that it can be designed in such a way as to provide innovative forms of information for teachers in the classroom. When students use technology during collaboration, there is the potential to provide teachers with live data about student’s activities that can benefit the learning process (Van Leeuwen, Janssen, Erkens, & Brekelmans, 2014), and emerging possibilities to use data analytics to provide live analysis of this data to help teachers understand the meaning of the data. Data analytics can be especially beneficial to support collaboration by visualizing information that may otherwise be invisible to teachers, allowing them to attend to activity and interactions that can be difficult to identify (Martinez Maldonado, Kay, Yacef, & Schwendimann, 2012). One example of this is a tool described by Mercier, (2016), where findings show that teachers were better able to notice patterns of activity and allowed them to intervene at the individual, group, or whole-class level as was deemed appropriate.

While there is ample research on the design of software using educational design principles for students (Frye & Soloway, 1987; Krumhansl et al., 2013; Lewis, Brand, Cherry, & Rader, 1998; Najjar, 1998), we know little about how the design of technology influences what teachers do in the classroom. According to Paas & Sweller, (2014) in order to create a successful multimedia experience, interface designers must create a tool to reduce cognitive load so that users are not overwhelmed with extraneous information while completing multiple tasks at once. Teaching is a complex endeavor, and teachers are already processing a high information load while attending to the students in the classrooms, creating the need for an intuitive and informative orchestration tool. One method to address this is to understand how the different components of the software influences the audience directly (Norman, 1983), often by including users in the design process. By including teachers in the creation of these tools, we gain a better understanding to what is needed in the classroom while also increasing their comfort and belief in the tool (Cviko et al., 2014). Another way to reduce extraneous load for the teacher, is to be conscious of the design decisions when creating representations. When using live data from a classroom, it is important to represent graphical information in an intuitive format that allows users to interpret information, notice patterns, and integrate it with their knowledge of what’s happening in the classroom (Carpenter & Shah, 1998). There are various guidelines in the multimedia literature that have been created to facilitation the understanding of graphs (Ratwani, Trafton, & Boehm- Davis, 2008; Shah, Mayer, & Hegarty, 1999) and cue users to relevant information for their task (Richter, Scheiter, & Eitel, 2016; van Gog, 2014). By understanding and using these guidelines designers can create software that allows teachers to extract information without disrupting the classroom or their attention to their students. If tools are developed to provide insight into group work, it is necessary to ensure such tools provide only useful information, and are
visually designed to be simple and quick for users to understand what is being displayed and the appropriate actions they need to take based on the information they receive. In order to address these issues, the research questions addressed in this paper are:

1. What do teaching assistants (TAs) anticipate they need in order to successfully support collaboration?
2. How can their ideas, in tandem with design theory and classroom orchestration research, be used to inform the design of orchestration tools?

Research Method

This study took place in the context of a multi-year design research project (Anderson & Shattuck, 2012) situated in a large, introductory engineering course which is in the process of integrating collaborative problem-solving activities into discussion sections. The project focused on the design of tools to support the creation of joint representations within groups, and the design of tools to support the TAs in these classes. TAs were graduate or undergraduate engineering students, with minimal teaching preparation. This paper focuses on the design of the TA tools.

Participants

Fourteen engineering teacher assistants (TAs) participated in the study. All participants were working as teaching assistants at the time of the study and were recruited during their weekly TA meeting. Ten of the TAs were in their second semester as a TA; the remaining participants had completed between three and six semesters in their position.

Interviews were conducted with one or two participants at a time, for a total of ten interviews. Interviews were separated into two phases, with changes to the information and design between the phases. Each phase had 5 interviews. One participant from phase 1 also participated in phase 2, thus there were 8 participants in phase 1, and 7 in phase 2. Interviews were audio recorded, and consent was obtained from all participants prior to recording.

Teacher tool

Students in the discussion sessions work in groups of 3 or 4 to complete collaborative problems, using synced tablets that allow each member of the group to work on a tablet, while seeing the work of the rest of their group. A maximum of 8 groups participate in a class at one time, leading to a maximum of 32 students in the class. Log files from the tablets, paired with video analysis of the groups, are being examined to identify group processes and will form the basis of information provided in the TA’s orchestration tool. This tool is not intended to replace normal in-person monitoring, but to help advise novice teaching staff, who lack the experience to easily identify the quality of group processes, to more effectively support groups.

Our previous work has found that TAs, who are often the people tasked with implementing collaborative learning in STEM courses, lack experience in identifying collaborative processes, and provide little beyond content support to students, thus they may benefit from more explicit insight into group processes (Mercier et al., under review). In this stage of our work, we created different representations of an orchestration tool, to prompt discussion during the interviews.
The teacher tool displayed all eight groups in the class; each student in each group was represented as a color. The color of each group member was also displayed at the top of the app on each student’s tablet to distinguish which student was which to the TA. The teacher tool presented the TAs with three categories of information for each group: activity, progress, and location. The three categories of information were derived from previously conducted focus groups with K-12 teachers who had experience using collaborative learning in their classroom. These initial focus groups provided insight into the types of things that more expert teachers looked for in their classrooms, although with recognition that their classrooms differed in terms of content, age of students and frequency, and length of relationship with the students (e.g. most k-12 teachers see their students multiple times a week, for at least one school year, and sometimes for multiple years, whereas TAs are likely to see the students for one 50-minute period a week, for one semester). Thus, their insight provided expert views on teaching collaboration, which needed to be adapted for the context of undergraduate engineering discussion sections.

The first category, activity, was used to visualize how much a student had written on the tablet and was displayed in two ways: student activity and group activity. The student activity (figure 1a) displayed how much a student had written on the tablet compared to the other three group members. The group activity displayed how much each group had written compared to the rest of the groups in the class (figure 1b). This was used to allow TAs to identify if one group was writing more or less than other groups.

The progress visualization indicated how much of the worksheet the group had completed (figure 1c). Finally, location displayed which page of the worksheet each student was on within their group (figure 1d). This was to indicate to the TA if a group was progressing through the worksheet at the same pace or if someone was working ahead or falling behind.

![Figure 1: Categories of information in each design. Student activity (a), group activity (b), progress (c), and location (d).](image)

**Interview Protocol**
Two members of the research team attended each interview, one was the interviewer and the
other took notes. The interviewer used a semi-structured interview protocol. Data was collected through notes and audio recordings. The interviewer gathered demographic information, explained the scope of the project, and introduced the participants to the information being visualized. Participants were presented with different designs for the teacher tool, one at a time, and asked the same questions about each. The questions focused on how participants interpreted the information from the designs and how they thought they would use it in their classroom.

To introduce each teacher tool design, participants were first told to take a few moments to look at all 8 groups being presented, then asked:

a) what can be inferred about these groups,
b) explain the process they would use to analyze the information
c) what would they do after viewing this information.

Once the information was familiar to them, the interviewer introduced the same teacher tool design populated with different data and asked to identify and explain what different groups were doing. The moderator completed the interview by asking:

a) which piece of information is most and least helpful during discussion sessions,
b) would they use the technology in their discussion session
c) what additional features would they want it to have.

Analysis
Emergent themes were identified using notes and audio recordings from the interviews, and discussed among the research team.

Phase 1 Design
Participants were introduced to different teacher tool designs during the two phases of interviews. Phase one (see figure 2) included a range of simplified representations. The first phase of the interview only included group activity, location, and progress; student activity was not included in this phase. Group activity was represented as bar and pie graphs; progress was represented as check boxes, on their own and overlaid on the worksheet pages; a student’s location was represented as a dot under the worksheet pages.
Figure 2: Teacher tool designs in the first phase of the interviews.

Phase 1 Results
During phase one most participants valued the bar chart over the pie chart, because they could easily identify who was working the most among groups. Most participants appreciated the third design because it displayed a preview of the content of each page, whereas in the remaining three options it was difficult to remember what the content of the page was.

In order to determine which category of information (group activity, progress, and location) was most useful, in the first phase participants also gave feedback on which of the three pieces of information would be most helpful in their classroom. Results indicate the majority of TAs preferred activity over the other two, but most saw potential in combination of all three. However, one significant suggestion from the first phase of interviews was to include the difference between individual and group activity. In this first phase, activity displayed how much each student had written compared to the rest of their group, but did not include how much each group had written compared to the others. This allows the TAs to identify groups that may not be working.

Phase 2 Design
With feedback from phase one, we were able to redesign and make changes to the teacher tool designs in phase two. In phase 2 of the interviews, participants were introduced to 4 more designs (see figure 3). Using feedback in phase one, phase two included student
activity and group activity, all designs displayed a preview of the worksheet pages, and
used a square tag to indicate location on the pages rather than circles. Progress was
visualized using the boxes in the upper left corner. Group activity was visualized as a line
graph in all four designs. Student activity was visualized using three different graphs.
Design 1 displayed student activity as a bar graph, design 2 as a Gantt chart, and design 3
displayed student activity as a bar graph within the location position, and design 4 excluded
the student activity category. All four teacher tool designs included different visualizations
and altered layouts for the information.

Phase 2
Results

In order to understand which design was most useful, participants in phase 2 chose which of
the teacher tool designs was the best option to use in their classroom. Results show that there
was a consensus across participants, as the majority of participants chose design 4. However,
all participants preferred the student activity visualization in design 3, where it was combined
with the student’s location. Due to this feedback, the final teacher tool to be implemented in
the classrooms was design 4 with the student activity visualization from design 3 (figure 4).
Discussion

This study set out to understand the perceived needs of TAs to inform the development of technology that will enable them to monitor group processes. To answer the research question, what do teaching assistants anticipate they need in order to successfully support collaboration, we analyzed interview responses. Our overall findings from both phases of interviews, suggest that TAs found more value in the activity category, but that in conjunction with the other categories (location and progress) the tool provides valuable insight to what is happening in groups that would not otherwise be observable. Although, as we know from prior research, TAs have little experience with collaborative work. This may indicate that additional prompts or visualizations may be necessary to help novice TAs know how to intervene with groups (i.e. observing before intervening), not just monitoring what is happening.

To answer our second question, we used the TA’s responses in light of our understanding of the literature, to make changes to the design of the software. Many of the responses and ideas from the TAs were consistent with guidelines in the literature. For example, including worksheet pages in the visualizations will reduce working memory needed to remember the content of the pages, using line graphs to illustrate change over time allows TAs to extract patterns without difficulty, and implementing color to signal groups and students will reduce extraneous information from the TAs while also indicating groups that may need help.

Follow up interviews, as well as video analysis of the tool in use, will be used to inform the next stage of design. Future work of this software will investigate how to embed prompts for
TAs to not only identify when collaboration is happening, but understand how to intervene effectively without disrupting group work.

**Conclusion**

Designing tools for classroom orchestration requires that we consider not only the information we can provide, but the type of information that would be most useful to teachers, and the manner in which they can easily review this information and make pedagogical decisions based on the information. After completing this study, we also suggest TAs need flexible orchestration tools, where information can be quickly extracted, and adapted as they develop as teachers, in order to allow them to effectively monitor and support collaboration. We also want to emphasize the importance of user centered design. Including the TAs in the design process gave them the opportunity to reflect on their experiences and give feedback on a tool that will be used in their classrooms, this allows the research team to create a tool that addresses the needs of the TAs and their classroom. Bridging the gap between researcher and user introduces a successful collaboration between the two forms of expertise and increases the likelihood of a successful design.

Her research focuses on the design of classroom technology to support collaborative learning. She is PI on two NSF grants that are focused on collaborative learning in engineering classrooms, and has a number of other grants that focus on collaboration in the K-12 classroom. Recently, her team published an iPad app to foster discussion and collaboration around issues of climate change and food choice (www.foodforthought.illinois.edu).
User’s Expectation on the Feedback of Flexible Interaction

Jaemyung Lee, KAIST, Deajeon, Republic of Korea. mailto:shurei@kaist.ac.kr

Abstract

Flexible interaction technology became a one of key technology in nowadays. On the other hand, there are relatively little works has been done to understand how it should be designed especially for feedback of it. In this study, we investigate the guidelines for design feedback to flexible interaction systems through based on user’s expectation on them. We conducted user participated design workshop to collect user’s perspectives about feedback when they use flexible interactions. We gave 8 sets of actions which are generally used in flexible interaction and let 6 participants to generated ideas about visual, sound, and haptic feedback of them. From discussion session in the design workshop, we found out key factors about feedbacks. As a result of design workshop, we build guidelines of designing feedbacks for flexible interactions. This result will lead system designers to build flexible interaction to create flexible interaction which can improve the user experience.

Keywords: Feedback, Feedback Design, Flexible Interaction, Design Workshop, User-Centered Design

Introduction

Flexible interaction technology is a bright technology that is expected to change user experiences (UX) in future human-computer interaction (HCI) due to its novel characteristic of flexibility and tangibility. On account of its novel characteristic of flexibility and tangibility, many researchers have been finding a new possibility of UX in flexible interaction. Also, many companies in HCI field tried to apply it to their new products.

Nevertheless, there is only few understanding about flexible interaction. Flexible interaction research studies in the HCI field mostly focused on developing an experimental prototype for interaction to find out novel interaction (Dijkstra et al., 2011; Girouard et al., 2015; Gomes et al., 2013; Kildal et al., 2012; Lahey et al., 2011; Ramakers et al., 2014; Schwesig et al., 2004). Most of them concentrate on building a novel input system with the flexible interaction. In contrast, there is the lack of understanding about how a computer should give feedback to a user when they use flexible interaction as an input signal.

Although some researchers tried to understand flexible interaction in the point of view of users, they only focus only how user manipulate them (Lee et al., 2010; Warren et al., 2013).

The main purpose of this study is to explore how user expects feedback to their flexible interaction device. In this study, we conducted user participated design workshop to understand about their expectation. As a result of research, we provide some guidelines that will help to design a feedback in flexible interaction which is an essential part of building an interaction and interface of a system.
Background

Nowadays, the various applications of flexible interaction have been developed, starting with the Gummi, which is a bendable computer prototype (Schwesig et al., 2004). From the starting of the Gummi, many researchers constantly proposed about new concept of interactions based on flexible display technology (Dijkstra et al., 2011; Girouard et al., 2015; Gomes et al., 2013; Kildal et al., 2012; Lahey et al., 2011; Ramakers et al., 2014). However, most of them only concentrate on finding novel and specific methods of the flexible input system. In contrast to the thorough understanding of input situation, there is a lack of understanding about feedbacks of flexible interaction. Most of their system did not include about feedback itself (Dijkstra et al., 2011; Girouard et al., 2015; Gomes et al., 2013; Ramakers et al., 2014). Moreover, although they consider about feedbacks in their system, they just followed traditional feedbacks in desktop, smartphone, and tablet (Kildal et al., 2012; Lahey et al., 2011). Dimitriadis et al. developed notification system based on flexible interaction (Dimitriadis et al., 2014). However, in their new interaction system, they just use flexible interaction as an output of computer system. Several researchers did studies about how user interact with a flexible device (Lee et al., 2010; Warren et al., 2013). They tried to figure out that what kind of action user prefer in flexible interaction. On the other hand, in their research, they did not consider about how computer system should react to the flexible input as a feedback. Thus, in this research, we conducted an ideation workshop to explore the user’s expectation on the feedback of flexible interaction to draw a guideline of feedback styles in flexible interaction.

Study Methods

As this user research was an imaginary future device, a flexible display device, we conducted design workshop (Chen et al., 2012; Mori et al., 2013) to determine what kind of value user wants on the feedback of flexible display. The objective of our design workshop was for participants to generate with design ideas about feedbacks of flexible interaction and unearth why they design in that way. To achieve that aim, we recruited 6 participants who have an experience with design interface and feedbacks of them. The average age was 23 (from 20 to 27, SD=2.46); 4 of them were men, and 2 were women. All participants have their own

Table 2. Result of design workshop (Participants 6 / Action 5-8)
smartphone and tablet at least 1 year. For the first session of design workshop, we gave them 8 different flexible actions (figure 1) which are general actions in two different materials; paper and plastic sheet (Lee et al., 2010). For each action, we let participants generate visual, sound, and haptic feedback. We provide several sheets of A4 size paper and OHP films, pens, post-it, and marker. We gave 48 minutes for the design workshop, which means 6 minutes for each action. Then, all participants shared their ideas and discussed why they designed feedback in that way.

**Result**

We conducted ground theory method (Pandit, 1996) to extract main keywords from participants’ idea result and discussion points. Table 1 and 2 shows results of feedback design workshop. To analyze visual feedback, we focused on where the feedback starts. For sound, we considered the motivation of sound and the pattern of it. Finally, for the haptic feedback, we mainly focused on the duration of haptic feedback. The results are written in table 1. When all participants show same comments, the table was colored green; conflicted opinion was colored blue or red.

**Discussion**

**Visual Feedback**

For visual feedback, there are two tendencies among users. The first tendency is to make starting point of action as a starting point of visual feedback. For the action 1 (Bending Upward), participants 3, 4, 5, 6 make feedback which obumbrating side part where user held and flex. On the other hand, participants 1 and 2 make feedback which highlighting center part where the actual task occurs. These results show another tendency that makes task part as a starting point of visual feedback. This tendency is also shown in another action except action 8 (Bending the right upper corner). In the case of action 8, because the task point is equal to action point, all the participants agree with highlighting that position. In general computer systems like desktop, smartphone, and tablet, the task point is always identical with an action point. For that reason, in a traditional system. However, in the flexible interaction system, disconnection between the task point and the action point frequently happen. When designer design visual feedback, they should pay close attention to decided where should be a starting point of visual feedback.

**Sound Feedback**

In the case of sound feedback, use tends to use the natural sound of that action. For action 3, 4, 5 and 8, participants build sound feedbacks based on the sound when the materials move in that way. Participants 3 mentioned, “Because it sounds like it if the system gives me that sound, I will feel more natural interaction for it.”. Users want to feel more naturalness while they interact with their flexible device by sound feedbacks from a real world. Another interesting point is that user wants continuous sound feedback during the action, not the task. Participants 5 commented “I am not sure that my input is ongoing or not. So, I want to know it when I manipulate the system.”. Moreover, for action 1, 2, 6, and 7, participants designed volume or pitch is proportional to the degree of flexed area for their sound feedback. For action 6, Every participant agrees that while bending right side more, the pitch
of sound feedback should be high. This shows the continuous and tangible characteristic of flexible interaction (Warren et al., 2014). In flexible interaction system, the degree and the angle of action can be changed. For this reason, users want to system reacts to their degree and angle of action while they use flexible devices.

**Haptic Feedback**

For the haptic feedback, as same with sound feedback case, users want to continuous feedback on their action. One different point is that they want to know when the task actually done by the bigger vibration. In case of action 4,5 and 8, participants build feedbacks small vibrating during action, and finished with bigger vibration when task actually happened.

**Conclusion and Future Work**

In this study, we aimed to understand user’s expectation on the feedback of flexible interaction system by user participated design workshop. By doing this, we could extract design guidelines which designer should consider. For designing visual feedback, designers should consider where will be the starting point of visual feedback between action point and task point. In the case of designing sound feedback, designers should consider about continuity and degree of action. As the last, for haptic feedback, designers should consider about both action and task.

It is true that our study has a limitation on adapting real flexible interaction prototypes. However, we hope that this study will provide both designers and engineers helpful implications and reference for developing interaction system which increases the user experiences.

Pioneers of Sensory Development Education: Christof Drexel and Hugo Kükelhaus

Andreas Luescher, Bowling Green State University, Ohio, USA, aluesch@bgsu.edu

Abstract

Two German pioneers of sensory development education, Christof Drexel (1886-1979) and Hugo Kükelhaus (1900-1984) pursued methodical investigations into perceptual principles of cognition and design in order to discover the ways in which aesthetic principles can develop and guide sensory response. Drexel and Kükelhaus traveled parallel investigative paths, both merging formal aesthetic practices with perceptual psychology. It was not until 1950, when these visionary thinkers finally met in person, that they joined forces to present their discoveries which determined that experiences are momentary intersections between internal and external realities, and are intrinsically intertwined in the deepest levels of consciousness, publicly. Both Drexel and Kükelhaus believed in the value of using the senses as pedagogy and that they should be integrated into every level of education. Correspondence between Drexel and Kükelhaus after 1950 illuminates the theoretical paths and applicative forms generated through the interplay of experimental psychology and applied aesthetic practice. This paper provides insights into the artistic and scientific dynamics based on Drexel’s examination of archetypical imagery and the psychic line, and the sensory development applications designed by Kükelhaus.

Keywords: Autodidacticism, Design environments, Models of design processes, The sensuous idea, Intuition

A Sense of Connectedness

Christof Drexel (1886-1979) and Hugo Kükelhaus (1900-1984) were two men, 14 years apart in age, who travelled virtually parallel paths as artists, educators, and theorists until 1950, when they finally met. Since both Christof Drexel (Figure 1) and Hugo Kükelhaus (Figure 2) are not well known in the English-speaking world, a short outline of their theoretical paths and applicative forms generated through the interplay of experimental psychology and applied aesthetic practice is needed. Drexel grew up in the charming town of Königstein, near Frankfurt along the Rhine River, where artists, intellectuals and the wealthy gathered to partake in the healthy air, natural spring water, and exquisite local wines. He studied medicine and architecture in Munich for one year before switching his focus to art. His early subjects, primarily people, animals, and landscape, were aligned with the German Post-Expressionistic Movement (Das Bundesarchiv, 2017). However, after WWII, and the shift toward a greater internalization, his paintings became more abstract in nature. His work ultimately evolved into a concentration on physiognomies and human representations so viewers could observe human behaviors and emotions as social-critical content (Günther, 1977). In contrast, Kükelhaus lived near the city of Essen and grew up as the oldest of five children, all of whom were connected to the crafts because his father was chairman of the Carpenter’s Association. In 1919, Kükelhaus finished his Abitur (certificate of general qualification for university entrance) and began his apprenticeship as a carpenter and travelling journeyman. In 1925, he received his Master Carpenter’s Certificate.
and as a natural-born pedagogue, began lecturing to common carpenters on the subjects of
“Proportion, Harmony and the Golden Section” using only a sunflower and a dandelion as
objects for demonstration (Schenkel, 1991). Drexel, on the other hand, changed his career path,
traveling to Paris (Academy Julian), Rome, and London before settling in Hagen in 1911 to join
avant-garde art patron, Karl Ernst Osthaus and the Folkwang Circle, known for espousing the
interconnection of the arts and interdisciplinary teaching, learning and producing. Osthaus
envisioned a Gesamtkunstwerk that would transform Hagen, a city plagued by all the ills of
industrialization, into a model of social reform. This group of artists were charged with the task
of discovering the defining principles of form and the psychological effects that art and design
could have on reinvigorating this industrial region. Drexel searched for insights into the
configurative process of image-making in the art of children and the mentally ill (Petzet, 1950).
The experience of anxiety and fear became a dominant theme for Drexel who became
increasingly interested in choric drawing (from German Chorisches Zeichnen), in which patients’
drawings became a form of creative therapy that creates a more positive self-view. When Carl
Jung heard about this technique, he was very interested, because of his own goal to deepening
this aspect of physio-psychic group therapy. In contrast and continuation, Kükelhaus started to
pursue methodical investigations into perceptual principles of design in order to discover the
ways in which aesthetic principles of design can develop and guide sensory response (Luescher,
2015). Constructive Perception is grounded in the understanding that mental action and
perception share a common representational substrate which mediates between the two through
inference and associative operations. Eventually Kükelhaus’s focus became centered on the
aesthetic dimension as an essential quality of auto-didacticism and finding deep meaning in
everyday forms (Willi, 1995). The result became Spielzeug Allbedeut (All Things All Meanings,
1939), first toys for infants based on the observation of the need for development of
opportunities to enhance the creative arrangement of simple to complex forms. However, it was
not until the 1950’s that these two pioneers of sensory education were introduced to each other,
which gave rise to an intellectual correspondence on Mensch zu Sein (To Be Human) which lead
to a deep friendship. Many years later, when Drexel passed away, Kükelhaus wrote a eulogy for
him entitled Den Menschen Ermöglichen (Allow to Be Human).
Figure 1: Christof Drexel self-portrait, undated. Source: Unknown.
Chorische Zeichnung

Drexel and Kükelhaus’s interest in the psycho-physiological substratum of learning, the *erfahrbar* (can be experienced), led them to experimental investigations into creative consciousness and sense-based learning (Luescher, 2006). There are two ideas: Drexel’s Chorische Zeichnung (choric drawing), an experimental method of whole body, whole mind restorative physiotherapy, and Kükelhaus’s wooden toys, *Greiflinge* (there is no exact translation word for it but teething and rattles comes to mind), for infants and toddlers which help foster the comprehension of deeper and subtler patterns within the conscious experience as an analogue to forms in the natural environment where the endless interplays and variations of shape continually stimulate curiosity (Figure 3).
Much of the correspondence between Drexel and Kükelhaus has reference, in some form, to the choric drawing Drexel developed with the help of the Folkwang Circle. Choric drawing initiates an inferential process of exchange between mind and body that becomes manifest through visualized gestures (Figures 4 and 5). Drexel and Kükelhaus believed that formal sense pedagogies should be integrated into every level of education. For instance, Drexel wanted to make it clear that the cultivation of sight should be considered a discipline, a responsibility, that needs to be consciously pursued. This type of sight goes beyond the sight of conventional reality by focusing on intuition, feeling and the psyche. Similarly, Kükelhaus lamented the dearth of opportunities to use our bodies, to turn off and repress our senses. Over hundreds of years people have been replacing experience with knowledge, living in a world of artifice. Per Drexel’s writing, the essence of art is not the aesthetic and decorative, but rather its capacity to heal. In Drexel’s mind occurs when a person reconciles with and becomes at one with the world. Kükelhaus’s interest and support of choric drawing was instrumental in its promotion and recognition for art as therapeutic practice, as well as a plea for active sensory learning.
Figure 4: Postcard with a drawing from Kükelhaus titled Träumling mit Blütenzweig (child with a Blossom Branch), uncertain about date (1960), sent to Drexel which highlights Kükelhaus’s notion of aesthetic principles of design and sensory learning. Source: Hugo Kükelhaus Archiv, City of Soest, Germany.
Between 1911 and 1920 Drexel created a series of emotionally impacting charcoal drawings which explore the expressive qualities of primary visual elements. In these works, lines, dots, x’s, circles, and space communicate complex familial and social relationships (Figure 6). The child appears in Drexel’s work as both demonic and divine. This inwardly directed process of drawing, practiced by Drexel, emerges as a primal sketch, rooted in a universal schema. Drexel’s experimentation into a line as a transcribed gesture, led him to develop a form of restorative group therapy. He described his method in 1950: "The choric drawing is guided by development, in which the visible formation is to be assessed only as a passage or a metamorphosis. In a deliberate renouncement of the standards of marketable success, the aim is to free oneself up for personal immediacy in the sense of an autogenous training. The natural interplay of the gifts and the free physical mobility of the process generally result in a sociable solitude from which the thematic domination and personal variation in mutual fertilization comes to unity" (Wankmüller, 1979). In Kükelhaus’s work, he refers to choric drawing as Symmetry Drawing (Symmetrischen Malen), a longing for the discovery of the body which must be seen within universal dynamics because symmetry (from the Greek: agreement in dimensions, due proportion, arrangement) refers to a sense of harmonious and beautiful proportion and balance (Figure 7). Human feelings, properties, and characters, along with forms of facial expressions, gestures, body language and movement in space (as in miming), can all be recorded as a technique of symmetry drawing. Only in the conditions of symmetry, where all things are equal, can invariance be experienced.
Kükelhaus explains this as a decisive step in which following generations will discover the body as a dynamic universe (also known as universal dynamics). People are now starting to use the external universe to discover themselves: to see the world as a process, and experience as momentary intersections. Symmetry drawing brings the movement of people and their view of their environment into one composition.

Figure 6: Drexel’s undated drawing, an eclectic composition of three men, three clowns, contempt and longing. What do the children see? What do they hear? Source: Unknown.
The human body is normally bilaterally symmetrical with a single, vertical axis, as seen in the right and left hands with respect to the center of the body. This relationship is deeply and complexly anthropomorphic, and provides a schema for the recognition of the faces and bodies of others, as well as one’s own self-image. The bilateral symmetry of the organization of bodies also provides the conditions for upright movement, and the aesthetic and metaphorical values balance a fascinating interaction between right and left, which directly relates to on-going studies of the split-brain: the left hemisphere makes up stories to explain what the right hemisphere is up to. It also refers to the *interpreter phenomenon* and other findings, which indicate that the right hemisphere is inventive and interpretive, while the left brain is more logical and literal (Gazzaniga, 1998). Presumably Kükelhaus believed haptic (from the Greek, meaning to touch) motion, as in drawing, creates the ability to mirror ones-self. From his perspective, Kükelhaus (1980) saw a direct correlation between simultaneous movement of the right and left hands as a mental process that is able to divide an object into two mirror images (Figure 8).
Today, the idea of choric drawing has emerged as relational drawing, defined as a way of approaching the experience of drawing that allows us to feel and explore our relationships to ourselves, the world and others (Figure 9). This method is taught by the Drawing Lab at variety locations like at the Whitney Museum of American Art. “We begin with gentle movements, drawing our attention to our sensations, attending to the deep relationships of our own bodies: gravity and pressure in contact with the floor; a push generating an opposing lift or turn; lengthening, shortening; how these postures are interdependent. We gently explore the physical relationships that express themselves in how we move, breathe, and feel, and then in turn open these relationships up to seeing and resonating more fully with the movements of the world and other people” (Drawing Lab, 2017).
1975 Exempla

In the 1970s, Drexel focused primarily on the theme of *Formen des Menschseins* (Forms of Human Beings). In 1975, the artist showed, for the first time, his film *Maske und Gesicht* (*Mask and Face*) at the special exhibition Exempla in Munich, an International Crafts Fair, organized in 1970 by the Chamber of Crafts for Munich and Upper Bavaria. At the same Crafts Fair, Kükelhaus presented his installation “Field for the Development of the Senses” for the first time. An antecedent version titled “Field for the Senses”, was on display at the German Pavilion in the 1967 World’s Fair in Montreal. There were 12 stations selected from “Field for the Senses” placed in a gallery within the pavilion: roundabouts, swings, spring boards, rolling balls, swinging ropes, loops, a bicycle that drove a water vortex, a bell tower and more. Both children and adults gravitated toward these unusual play stations. Kükelhaus himself wrote the following for the EXPO 67 Handbook: “The principle demonstrated here, the discovery and development of which can be attributed to Goethe, has two very particular consequences. One is that art education must be recognized and integrated as a part of a systematic training for the ability to experience. This is not concluded with the maturation of the organism but is pursued and contributes to the conceptual processing of experiences, which begins at the same time as puberty. The second principle is that this processing takes place primarily in vocational schools and schools of applied arts, as well as community colleges and museums, because the experience
of art is integral in the great distinction of the organism’s capability to experience life” (Kükelhaus and Zur Lippe, 1982). The Field for the Development of the Senses grew to some 40 experimental and play stations, and then migrated to numerous locations in Germany, Switzerland and abroad. The stations are intended to offer visitors an opportunity to experience – in organic proximity – the laws of external nature (oscillation, gravitational force, polarity, reflection, color, etc.) and their interrelationships with the physiological laws of their internal nature (sensorial processes and bodily movements). These fields serve to extend a person’s capability to experience with their senses, so they may to experience things in a different way: as eyes see – ears hear – noses smell – skin feels – fingers touch – feet understand – hands grasp – the brain thinks – lungs breathe – blood pulses – the body swings (Figure 10). For, as Kükelhaus added: “It is not the brain that thinks but the human that experiences with their skin and limbs!” (Kükelhaus, 1978).
Figure 10: Hugo Kükelhaus demonstrated his swirl play station at the Expo’67 in Montreal. Source: Hugo Kükelhaus Archiv, City of Soest, Germany.
Currently, Drexel’s and Kükelhaus’s forms of sensory education are being further explored by Tommaso Lana’s (2017), an Italian teaching artist and educator trainer that offers workshops on rediscovering and heightening one’s sensory perception, *Embodied Learning*, where people use their senses at work, and in everyday life, in a distinctly mindful way. Lana’s research focus on how to nurture self-guided learning experiences in a very hands-on way through sensory perception, motion, and body awareness mainly targets adults who work with and for young children. Like Drexel and Kükelhaus, Tommaso Lana believes every single child’s identity is not only shaped by his/her brain, but by the collective whole of all his/her muscles, nerves and organs. A MOMA exhibition from 2012, *Century of the Child: Growing by Design 1900-2000*, acknowledged the importance of children experiencing for themselves the laws of external nature directly, and with all their senses.

Acknowledgment
I am grateful to Allison Faye, educator and visual strategist who introduced me to the work of Christoph Drexel. Jürgen Münch, Chairman of the Hugo Kükelhaus Society, and also Wolfram Graubner, a carpenter and author who provided me with archival insight in connection to Hugo
Kükelhaus. I am deeply indebted to Nancy Parsons, my writing coach, for her eloquent editorial assistance.

**Author Biography**

Andreas Luescher

Dr. Luescher is a Swiss architect, conceptual artist, and writer who is currently a Professor and Chair of Architecture and Environmental Design at Bowling Green State University, Ohio. His research is on design processes in architecture, design and urban design from an aesthetic, social, public policy, sustainability as well as visual culture perspective. He has written more than 80 papers for presentation at national and international conferences and for publication in leading international academic journals such as *The Journal of Architecture, Journal of Design Research, International Journal of Art and Design Education*, and *ArchNet-LIAR: International Journal of Architectural Research*. His first book, *The Architect’s Portfolio* (2010), has been translated into Chinese. His second book, *The Architect’s Guide to Effective Self-Presentation*, was published in 2014. He has authored two chapters published by Ashgate Publishing, and edited a special issue for *Urban Design International* entitled “Shrinking Cities and Towns: Challenges and Responses.” His latest book (with co-author/ editor Carolyn Loeb) The Design of Frontier Spaces: Control and Ambiguity, was published by Ashgate Press in 2015.

Eva C Lutz, MDes, Design Concepts, Inc.
Tricia Hertz, Ph.D., Principal Scientist, Procter & Gamble

Abstract

Outside of academia, it is often hard for researchers to find the opportunity to continue our scholarship. As graduate students and PHD fellows, we spent years creating and testing our hypotheses, designing new methods, approaches and technologies and we are anxious to ascertain if our theories can survive in the real world.

How does a lone researcher engage the business community and convince them to test and use new cutting-edge research methods? The flipside is also true, you are a corporate researcher who would like to engage new methods and approaches to advance learnings, but you have limited resources and a business that demands results. How can you trust new methods and engage in new approaches while minimizing risk and exposure? The authors will give a 50,000-foot view of a new design research methodology, The FlashDraw, and how it can be complimentary alongside traditional research methods. An overview and example of the research process will be illustrated. The poster will also explore the challenges and successes of the partnership between two researchers, a recent graduate student and a corporate researcher, and their on-going journey to explore and establish best practices for researching on the “edge of the new”.

Key Words: Design Research, User-generated Drawing, Methodology, Visual Language,

When innovation is the currency in which you trade, practitioners are often searching for new ways to identify the key insights that are the fuel for FEI, Front End Innovation. FEI, is defined as, “The starting point where opportunities are identified and concepts are developed prior to entering the formal product development process.” Wikipedia, 2017

With the increasing focus on business deliverables, designers, researchers, and innovators and consultants are being challenged to do it faster, better and cheaper. While traditional methods such as large global research studies and ethnographic research methodologies are were and, sometimes still are, considered best practices, innovative researchers are seeking new, lean (yet robust) learning avenues - the disconnect can be profound. This tension was one of the primary motivators to create a new methodology that would enable rich learnings via the collection of deeply emotional data quickly, effectively and from diverse populations. Creating the methodology is the easiest part of the journey to widespread adoption, the hardest part is acceptance and implementation in the field. This is especially true when the researcher is practicing in the private sector. This brief paper describes a new research method, The FlashDraw. It also briefly explores
some of the tensions associated with “selling a new method” and establishes general guidelines to aid internal and external researchers in the implementation of new methods to enable innovation.

**The FlashDraw, an Introduction**

How can we unearth deep insights remotely? We need to think beyond traditional methods, most of which rely on the collection of verbal or language-based data. Inspired by on-going research at the University of Cincinnati, a new methodology based on user-generated images was born. The research method, the FlashDraw, was designed to design to suss out the iconic images stored in the visual memory of a designated user population.

The FlashDraw method is based on theories and principles that how we remember, process and perceive images is different than for language or words. The human brain is hard-wired for image processing and image retrieval. Studies at MIT and the analysis of Magnetic Resonance Imaging (MRI) support this theory showing that the same parts of our brains are activated when we are looking at an object as when we imagine an object. This supports the theory of creative meta-seeing. Meta-seeing or creative imagery is virtual imagery that is visualized internal but externalized through our physical doodles, scribbles, charts and diagrams. When users are asked to draw, they are tapping into this virtual imagery. The images created by the research subjects are the projections of the virtual imagery they are seeing in their brains. (Kosslyn, Thompson, & Ganis, 2006)

These theories and understating the emotional content that are contained in images are why they help tell such profound stories and unearth such deep insights. Gathering user insights starts with listening to the stories of our research subjects. Storytelling is intrinsically a uniquely human quality. We began sharing stories as soon as we mastered the rudimentary skills that enabled us to communicate complex concepts. Our first shared stories were shared fireside; tales of beasts and conquists punctuated with gestures and pantomime. But our first recorded stories were drawn, images scratched into the sand or painted on hides and rocks; and visual narrative has continued to be a profound way for humans to share our fears, hopes, and needs.

A simple explanation of The FlashDraw method is illustrated below. Two groups of respondents were asked two similar, yet different questions. The first group of research subjects, a class of master of design students (n= 21) , were asked Question 1 “Please draw a picture of lunch?”. (Figure 1) is a representative sample of the images collected. The responses seem to very broad with many different types of food represented. But when we begin to analyze the data distinct differences emerge. (Figure 2), shows the same sample but it has now been filtered into US and International students. The two data sub-sets have now shifted into two homogeneous data sets, with multiple similarities in style of food, food temperature, serving container and utensils and inclusion of beverages.
The second group of research subjects, a US panel of adults ages 18-65 n= 100, where asked Question 2, “Please draw a picture of your most memorable meal experience.” A representative sample of these results are shown in (Figure 3). Both questions are very similar and are focused on food and dining, it’s immediately apparent that we have shifted focus from what is on the plate to the emotional context of meals in society and in our personal lives. Over 65% of the research subjects did not depict food in their images, instead images depicted concepts of togetherness, community, happiness, family, love and even our favorite brands. (Figure 4)
Implementation

You have managed to create something profound. You have tested your hypothesis, perhaps even written about it; but how do you move from theory to practice? How can you move into the adoption phase? It all starts with crafting a good story and finding someone to tell it to.

To help you on this journey we have created a check list of “What must be true to launch a new methodology in the real world”:

The Outside Consultant:

• Be brave! Find a creative curious champion who has access to funding.
• Create a simple and clear narrative and then simplify it again.
• Create a relevant demonstration of the value.
• Develop a generic case study you can share
• Create affordable and scalable engagement models
• Be willing to revise and amend deliverables
• Be open to challenge and change
• Don’t try to force fit your approach into the wrong opportunity

The Internal Champion
• Methodology is well-suited to enable me to learn against my business objectives
• Methodology is based on sound research principles & theories
• Trust and believe in this consultant
• Case study is relevant and believable, enabling ‘What’s Possible? / How Might We?’ thinking enabling me to adapt to my business needs
• Cost is reasonable, so that it is realistic to authorize or secure ‘seed’ funding
• Learning is experimental with high potential.
• Be willing to accept “This might fail!” yet know we will still learn
• Clear methodology and examples, enabled internal Corporate champion to justify and communicate business value to corporate sponsors and management

We have been on this journey for over three years and are still learning how best to optimize our project partnerships. We are willing to learn from each other and from the process; most importantly we adapt and change to achieve successes. This is all possible because of the factors we have outlined above.

Conclusion

Throughout the last three years that we have been experimenting with the FlashDraw. The two constants have been in our desire to learn and our faith that there are profound insights that can be found in user-generated imagery. Rigorous repeatable research practices are needed to validate new methodologies. Data only has value if it is trusted. The FlashDraw was developed specifically to address the need for a more rigorous method that could be applied to the collection and analysis of user-generated imagery. We are hoping to share a full case study with actual data in 2019.

User-generated visuals could fuel the design of visual concepts across the entire sphere of design and innovation and is a natural fit for the FEI research and discovery phase. The stored visual memory of the user needs to be elicited through user-generated drawing versus keyword searches or even standard participatory visual methods such as collage. It is our hope that this brief case study example and our “soon to be” shared projects provide a starting point for the validation of a design research methodology, The FlashDraw, based on a user-generated drawings.

Author Biography

Eva C Lutz

Eva Lutz is a seasoned industrial designer, design researcher and innovator. She is a design leader who delivers innovative human-centered design solutions that are grounded in the business strategies of her clients. Ms. Lutz obtained her Masters in design from the University of Cincinnati. Her thesis and research focus is on user generated images and how they can be leveraged for insights and innovation. As a practicing consultant and General Manager for the San Francisco office of Design Concepts, she designs products, strategies and research methods that create paths of success for clients in the US and world-wide. She has innovated and co-created across service, healthcare, CPG, automotive, and food and beverage categories. As a toy inventor and designer at Kenner, she co-created the Littlest Pet Shop, which has brought joy to children across the world for over two decades.

Tricia Hertz

Tricia Hertz is an expert innovator, scientist and R&D leader at P&G for over 25 years. She has delivered both upstream and downstream business results across many fast-moving consumer good categories by translating complex consumer and technology insights into actionable business recommendations and meaningful product propositions. Dr. Hertz earned her Ph.D. in Analytical Chemistry from Duke University (’92) where she pioneered the application of phase-resolved fluorescence spectroscopy & unique data analysis approaches to real-world problems.
Triangulation as an experimental approach: Interpreting the synergistic relationship between the visual syntax, practical mechanisms and theoretical frameworks of typography used in brand marks of cultural festivals.

Abstract

Typography is an important visible element of a cultural festival’s brand mark, yet is overlooked within cultural festival research. An abundance of work has been published that examines cultural festivals from cultural, economic, tourism, and place-making perspectives, yet there is a shortfall in scholarly research addressing the key role typography performs to engage audience participation through cultural festivals’ primary brand driver – the brand mark. This paper critically considers triangulation as a constructive and effective research framework for enquiry into typography deployed in the brand marks of cultural festivals and provides a roadmap to further research. Offering an analysis of how and in what way typography is being used in the brand marks for cultural festivals, this paper contributes a discussion of appropriate research methods in the examination of this material. Triangulation is engaged as a research technique combining the methods 1) content analysis, 2) case study (text analysis) and 3) a semiotic analysis of typography as a framework to advantage three perspectives on typography, capturing the complexities of the phenomenon. Through a pilot study of 20 cultural festival brand marks from English speaking countries in 2016, the findings show that triangulation of three methods is beneficial to uncovering a rich and nuanced understanding of the role of typography in brand marks. Although many research methods are available to design researchers, the authors argue that triangulation, is an appropriate method to analyze typography used in the brand marks of cultural festivals as it allows for the emergence of a heterogeneous understanding of the discipline.

Keywords: typography, brand marks, triangulation, content analysis, design research

This study was motivated by the discovery that we know little about how typography’s visual syntax, practical mechanisms and theoretical frameworks are deployed in branding cultural festivals. A substantial amount of literature exists that explores various economic, geographic, cultural development and social elements of the festivalscape (Gibson, Waitt, Walmsley & Connell, 2008; Johansson & Toraldo, 2017; Taylor & Kneafsey, 2016). The shortfalls in scholarly research investigating typography used in branding cultural festivals was discovered through enquiry conducted across academic journal articles and publications from the fields of communication design, marketing, cultural interpretation, branding and place-making. This paper presents a roadmap for researching typography used in the brand marks of cultural
festival marks from English speaking countries in 2016. The preliminary results determined that 70% of the typefaces used in the brand marks emerge from text and not display typeface categories. Additionally, no typefaces resided in the Blackletter category. The authors suggest that the Gothic script of Gutenberg’s era bares no correlation to the contemporary cultural festivals brand positioning. Similarly, the omission of any Topical typefaces which reference time, place or style, highlights a lack of appropriate communication within these typefaces as is demanded from cultural festival branding. Initial findings also suggest that the primary role of case study (text analysis) in this pilot did not successfully generate the intended results and a change of approach within the case study is a course of recommendation. However, what was discovered indicated that 45% of the festivals in this study mentioned the key phrases— major, premier, famous or leading; indicating a place for further research into brand positioning statements. The preliminary findings from the semiotic analysis of typography uncovered a clever dichotomy within the meaning potential of the Edinburgh Art Festival brand mark highlighting the significance of a semiotic discussion in such a study. Lastly, the authors argue that although triangulation has been used frequently in science research and rarely in typography research it is a worthwhile instrument in the study of typography’s visual syntax, practical mechanisms and theoretical frameworks used in the brand marks of cultural festivals.

**Literature Review**

In the style of Bruce Archer, (Bayazit, 2004; Cross, 2006) it may be stated, that typography research is systematic inquiry whose goal is knowledge of, or in, the embodiment of configuration, composition, structure, purpose, value, and meaning of man-made letterforms, characteristics and systems. This definition of typography research, captures the breadth of previous research and proposes scope for future research strategies. The range of research methods used in typography research is comparable in its variety to the diversity of methods used in design research with a vast range of approaches drawn from the social sciences, the arts, the humanities and science among others traditions. An examination of the most appropriate research method with which to investigate typography, has not been previously attempted. With the evolution and maturation of the emerging field of typography research this is an important consideration and presents a challenge for researchers in typography.

**Research Methods**

Research methods are a systematized plan whose purpose is to establish the strategy for research and the course an investigation will follow. Although there are numerous definitions of what a research method is, Crotty (1998) states that, ‘research methods are the concrete techniques or procedures we plan to use – the certain activities we engage in so as to gather and analyze our data’ (p. 6). As mentioned, the assortment of research methods available to design researchers can be tricky to navigate. The use of qualitative research methods is
popular in design research. However, there are many research methods available for use including action research, surveys, interviews, questionnaires and meta-analysis. Though, for this pilot study which is part of a larger project with the purpose of examining typography used in the brand marks of cultural festivals, the authors have chosen triangulation as the key research method, intending to reveal the complexities of reading cultural festival’s brand marks. The three methods trialed are 1) content analysis, 2) case study (text analysis), and 3) a semiotic analysis of typography. The rationale is to facilitate a quantitative and qualitative interpretative approach allowing the visual syntax, practical mechanisms and theoretical frameworks of typography to be identified and characterized across a pilot study.

Triangulation

The purpose of triangulation as a research method is to enable three ways to examine material; to substantiate a study; and clarify disparate results by placing them in dialogue with one another (Mertens & Hesse-Biber, 2012). By incorporating three research methods the authors aimed to facilitate deeper examination of typography used in brand marks for cultural festivals. With the depth and breadth of findings and nuanced appreciation of the cultural subject matter greater than what either 1) content analysis, 2) case study (text analysis) or 3) a semiotic analysis of typography used in isolation might offer. An analysis capable of extending across the visual syntax, practical mechanisms and theoretical frameworks of typography obliges employing research methods supportive of contradictions, allowing for an exploration of the tensions of the phenomena (Olsen, 2004). Gaining three viewpoints upon the elements studied – that is the essence of opinions in qualitative methods mixing with quantitative methods will ensure that the study is robust facilitating a deep understanding of the topic (Olsen, 2004).

![Figure 1. Triangulation of Research Methods used in this Study. Meyrick, T. (2017).](1)

1) Content Analysis

Content analysis is a quantitative method which allows for patterns in communication to be made visible. Described as the study of human communication, content analysis is surprisingly, rarely used in design research. However, it is the longest established method of text analysis among the set of empirical methods of social investigation (Titscher, Meyer, Wodak, & Vetter, 2000).

Scholars have claimed that the only way to logically assess communication content is
through quantitative content analysis (Riff, Lacy, & Fico, 2014). The approach to an assessment of communication content is to reduce the text being studied to a unit by variable matric and to analyze that matrix quantitatively against a study’s research questions. Achieving this, enables unique insight into the structure of the content of the text. The approach is rule based and systematic, placing categories centrally within the analysis which allow distinct patterns in the typography to emerge. Here, the visual syntax and practical mechanisms of typography are assessed through the application of a quantitative content analysis. The iteration and frequency of typeface attributes is quantified illuminating patterns of use and application. However, the authors proceed knowing that meaning within the cultural artefact under investigations is complex and a content analysis will only capture a part of the whole under investigation.

2) Case Study (text analysis)

A qualitative empirical enquiry situated within a study’s real-life context, the case study method is widely used in design research. Its role in this paper as part of the triangulation framework is tested to survey written information from accompanying websites of the selected brand marks. Yin (2012) proposes, case study objectives are to gain a deep understanding of the case through guiding frames. Yin (2012) maintains, there is no recipe book for analyzing evidence, he recommends it is critical to piece together fragments into broader themes, relationships and matrixes. The case study method lends itself well to substantiating the content analysis and uncovering the theoretical keystones of typography, adding a layer of complexity and offering richer description of the case being studied.

3) Semiotic Analysis of Typography

In social semiotics, the process of communication is not reduced to a linear pathway with a singular accuracy of reproducing the message, rather communication is an open dialogue that allows for meaning exchanges within the site of cultural production and the social context (Halliday, 1978). When understood as a semiotic resource, typography performs as a social and culturally shaped mode used in representation and communication to make meaning within our environment (Kress & Van Leeuwen, 2001). Conceptualizing typography as a semiotic resource with its own actions and modes offers researchers a rich palette for an analysis evaluating typography’s role in branding cultural festivals. Here the use of semiotics serves to elucidate the visual syntax - the arrangement and construction of letterforms; the practical mechanisms - of placement, mediums and display; and the theoretical frameworks that underpin the history, usage and meaning potential of typography thus revealing the scope of significance and implication of usage. Brownie and Van Leeuwen (Brownie, 2009; Van Leeuwen, 2006) maintain that semiotic potentials of typography occur when pictorial qualities and expressive elements are evident in letterforms. This moves beyond what Warde’s and the Modernist argued for, that of ‘invisible typography’. Massimo Vignelli didn’t argue for typography to be expressive either. Noting that one can write the word ‘dog’ with any typeface and it doesn’t have to look like a dog, yet Vignelli offers that there are people that [think that] when they write ‘dog’ it should bark. The typography used in brand marks for cultural festivals often do indeed ‘bark’ combining a full suite of graphic features and as such semiotic potentials are rich, thus a semiotic analysis is well suited to this study.
Discussion

The 20 brand marks for this study were randomly sampled using a numerical survey on the top 200 results from a Google.com search for the term ‘2016 cultural festivals’. The resulting 20 brand marks emerged as 8 from the UK, 3 from Canada, 1 from Singapore, 5 from Australia, and 3 from the United States of America. A content analysis was achieved by placing the brand marks in a matrix against Bevington and Chong’s (2013) typeface classification system. Indicators of typeface attributes demarcated the brand marks into unit-by-unit variables. Bevington and Chong’s system (Figure 2) formally divides typeface attributes into either, display or text categories. Grouped under text is serif, sans serif and slab serif. Grouped under display are blackletter, topical and freehand. Although further groupings and extensions of typeface classification are allowed for, these were not applied in this small study.

Figure 2. Typeface Classification System. Bevington and Chong (2013).
1) Content Analysis

The content analysis revealed that although, as Cahalan (2007) states, there is a proliferation of typefaces, the typefaces deployed in the cultural festival brand marks populated only 4 of 6 categories. We hypothesise that the exclusion of typefaces from the Blackletter category emphasizes that the heavy angular Gothic script of Gutenberg’s era bares no correlation to the contemporary cultural festivals brand positioning. Similarly, the omission of any Topical typefaces which reference time, place or style, highlights that the effective communication demanded from cultural festival branding drew no connection within the characteristics of these typefaces.

From the analysis, (see Figure 3) the following patterns surfaced; of the 20 brand marks, 70% (14) of typefaces reside in the text category. This broke down to 25% (6) sans serif fonts, 30% (7) serif fonts and 5% (1) slab serif fonts present. With a prevailing 70% of typography falling in this category, clearly the text category resonates with cultural festival brand positioning. This category is wide reaching and traverses over 500 years of typeface designs. A prevalent 30% of these fonts reside in the serif category further demonstrating that the classic, bracketed feet of the serif typeface which originally emerged from carved inscriptions to the printing
press and lead type continues to be relevant in the digital age. 25% (6) of the pilot study brand marks were positioned in the display category, notably occupying the freehand section. These letterforms possess adorning flourishes with decorative and illustrative characteristics.

1) Case Study (text analysis)

The second method conducted as part of the triangulation framework is a case study where a text analysis was trialed. The aim is to examine the written information, namely key text phrases available on the festival websites in the hope of making visible explicit links between those discovered and the patterns which emerged from the content analysis. We analyzed the festival positioning statement, the history of the event and any other available descriptive text. Positioning the key text phrases in a matrix, specific themes emerged. 45% of the festivals in this study mentioned the key phrase group– major, premier, famous or leading. 35% of festivals mentioned community. 30% of festivals mentioned culture and, or cultural tourism with at least 5% mentioning the terms up to 3 times. Engaging was mentioned in 25% of festival text and unique settings was noted in 20%. Other phrases noticed at minor percentages were sustainable 15% with at least 5% of these mentioning the keyword up to 3 times. An unusual theme that surfaced highlighted that 10% of the festivals didn’t note any mention of the top 6 keywords; instead presenting, either no information – for a brand position statement; or the festival website used terms ‘delicious food’ and ‘contributing to betterment’. This 10% were the largest of the festivals in the study, namely Coachella Valley Arts and Music Festival and Glastonbury Festival.

![Figure 4. Case Study – Text Analysis (Festival websites mention of keywords Major, Premier, Famous or Leading) Diagram. Meyrick, T. (2017).](image-url)
2) Semiotic Analysis of Typography

Thirdly, a semiotic analysis of typography was conducted as the final method in the
triangulation framework. The analysis is performed on the Edinburgh Art Festival (Studio’, 2013) brand mark.

Initially, the visual appearance of the brand marks’ typography appears as a serif typeface. Connoting homage to the history of the city of Edinburgh in Scotland, this deployment of the serif seeks to communicate with an audience acquainted with reverence intertwined with the prestige and provenance of the old style of letterforms. However, upon closer examination, the typography performs synchronously on an ancillary level, communicated via the decorative embellishments present in the letterforms in this brand mark. Graphic cyan elements appear as contrasting diagonal lines overlaid on the yellow characters. These are positioned in the exact location one expects the serif brackets. This reforms what may have been a modest older style typeface symbolic of stereotypical serif attributes to aesthetically communicate a value system that possesses an enhanced, fresher and more vibrant outward façade. The calculated line break in the words Edinburgh and Festival function in unison with the vibrant graphic overlay cleverly cementing and connecting the festival with a fun, fresh, cool and youthful audience appeal.

Figure 8. (Studio, 2013) Edinburgh Art Festival, brand mark.

Thus, connotatively the brand mark communicates to both a prestige audience through the initial visual appearance of the serif typeface and resonates, or denotatively communicates with a youthful, modern audience through embellishments. When this dual meaning potential is read in combination with the diverse array of festival acts performing at the events, there is a stable and assured communication well suited to achieve the desired market share. From the initial findings of this pilot study the third method demonstrated the rich possibilities of a qualitative analysis which were undiscovered though quantitative methods. Further research is recommended that would consider how typography performs as a socially and culturally shaped mode across a number of festival brand marks.
Conclusion

This paper offers a reflective approach to examine typography within a triangulation research framework. Revealing the complexities of typography’s discourse this approach combines the triangulation of 1) content analysis, 2) case study (text analysis) and 3) a semiotic analysis of typography. The preliminary results of the content analysis, determined that 70% of the typefaces used in the brand marks in this study emerge from text and not display category typeface. No results resided in the Blackletter category, with the authors suggesting the script bares no correlation to the contemporary cultural festivals brand positioning. Similarly, the omission of any Topical typefaces highlights a perceived lack the effective communication within the characteristics of these typefaces. The authors aimed to align the identified patterns of typeface usage with the case study (text analysis) yet this resulted in an unexpected dead end.

The keywords identified in the case study (text analysis) presented no correlation with the typeface usage patterns. However, there are gains to be made here. This pilot study is part of a larger project and a secondary outcome is now possible with future investigations using triangulation steering away from a text analysis within the case study as the findings in this pilot study reported in this paper suggest it may not be worthwhile following this line of enquiry.

In addition, a semiotic analysis of typography deployed in the Edinburgh Art Festival brand mark uncovered a clever dichotomy within the letterforms. Accomplished through the potentials for meaning evident in underlying forms and overlaid graphic representations this highlighted that the letterform attributes effectively sought to reach a broad market audience.

A promising start to the triangulation framework, these findings suggest further research is advisable and although triangulation has been used frequently in science research and rarely in typography research it is a worthwhile method in the study of typography’s visual syntax, practical mechanisms and theoretical frameworks used in the brand marks of cultural festivals. This paper set out to critically consider triangulation as a constructive and effective research framework for enquiry into the typography used in cultural festivals brand marks. The triangulation framework allowed the emergence of a heterogeneous understanding of the area which would have otherwise been obscured. Offering a solid foundation to evaluate the typography used in brand marks of cultural festivals, the significance of this paper lies in its potential contribution to typography research and in providing a roadmap to further research.

Tonya Meyrick
Tonya Meyrick is an academic and communication designer based in Melbourne, Australia. She is a faculty member at Deakin University and Course Director of the Bachelor of Design (Visual Communication Design). Her research focuses on the intersection and boundaries of typography, place branding, semiotics, education, technology and design. As a communication designer, Tonya works with national and international corporate, community and not-for-profit organizations. She is also a PhD candidate with Swinburne University investigating the application and implications of typography used in the brand marks of cultural festivals. Tonya is uncovering systematic and emerging practices to develop and test new methodologies that chart the ways metropolitan and nonmetropolitan cultural festivals engage typography to express, explore and celebrate a community activity, place, a history or event. Tonya has taught, studied and spoken internationally about typography and design and is generally a typography nerd.

Simone Taffe PhD
Simone Taffe is Associate Professor in Communication Design at Swinburne University of Technology, lecturing in branding, participatory and inclusive design methods. When joining Swinburne as an academic Simone formed a research focus that builds on 15 years of practical experience in the design industry. This experience includes seven years as design manager for the City of Melbourne and design manager for the leading Melbourne design consultancy Flett Henderson Arnold (now Futurebrand), being involved in large scale high public profile branding projects. Simone's research addresses participatory design in communication design. Her research has involved external funding and real-world projects that have gained national and international recognition in the field of Communication Design through published research papers and through real-world design applications available on the World Wide Web.
The Development of Modern Design Methods through an Actor-Network Theory (ANT) Analysis of the Pre-modern Social Customs of Japan

Abstract

We analyze life in urban district on the outskirts of Tokyo by ANT. This research is used to identify social and technological elements that are regarded as essential in the modern day and to develop methods that will link to a practical approach. Our presentation describes these methods in detail. We believe that it may be possible to identify particularly important elements in design methods that respond to the complications of the modern day in early modern wisdom and customs, which until now have been overlooked. Today, as the foundations of social norms and traditions that have previously been regarded as self-evident are swaying and the risk society is advancing, these new design methods can be used to respond to an array of issues with a high degree of complication, such as the deterioration of the mental environment and environmental problems without any discernible solution. Since the modern era began, design has solved social problems through the development of objects and systems. However, in terms of the problems stated above, it can also be pointed out that design is both unable to suggest basic solutions and, in addition, forms a part of the social structures that cause these problems. Approaches that follow laws of causality tied to modern methodology cannot be applied to complicated problems where the relationship between cause and effect is unclear. The use of new design methods makes it possible to decipher complicated relationships and apply pre-modern systems to modern life.

Keywords: Methods &Tools, Fundamental Research, Design theory

1. Introduction

We believe it is possible to find elements of pre-modern customs and wisdom that offer important design methods appropriate to complex modern times, but that have been overlooked as outdated. In pre-modern customs and traditional practices, one can find structures for handling risk as a whole community, methods for community maintenance, and ways of connecting individuals, society, and tradition.

Under the conditions of modernity, in which foundational structures that have long been taken for granted, such as social norms and traditions, now shake and tremble, this way of thinking is an appropriate approach to the highly complex problems afflicting modern society, such as the devastation of the mental environment, and environmental problems that go on without solution. Since modernity took hold, design has played a social role by discovering social problems and developing goods and systems to address them. However, regarding the problems of modernity, not only has design failed to present fundamental solutions, it is also part of the social structures
that cause such problems. Is this not because design is itself bound by the law of causality, and thus to modern methodologies? Approaches conforming to the law of causality cannot cope with the set of complex problems in which relationships between cause and effect are unclear. Therefore, new design methodologies are necessary.

In this paper, we use Actor-Network Theory (ANT) to analyze a case study in the municipal suburbs outside Tokyo. By doing so, we show how it is possible to understand complex relationships and apply pre-modern systems to modern life. The purpose of this research is to use that juxtaposition to develop a method that leads to a more concrete approach to finding the social and technical elements necessary for the present age.

2. The situation of modern design and the necessity of reconsidering design methodologies

Risk Society (Beck, 1992) is a society in which the risk reaches a dimension that puts life at risk on a global scale, and risk becomes increasingly influential to the development of society and the living environment. The dangers of the Nuclear and Chemical Age are diverse, and include the collapse of the food chain, global environmental destruction, the possibility of global financial collapse, and other human-made risks that threaten society itself. Beck and Anthony Giddens (1994) use the term Reflexive Modernization to describe the present condition of modernity, which is entering a stage in which the self loses aim and purpose as it modernizes. The mechanism of self-harm in Risk Society is a distinguishing characteristic of Reflexive Modernization.

However, design developed in hand with the industrialization of the 20th century, and has been focused on solving the “problems” of inconvenience and discomfort. Design has succeeded in solving social problems by creating new products and services. While there is a certain significance in this form of “problem-solving” structure, it also has its limits. The design methodology that succeeded was one that, in the process of modernizing subjects such as nature and tradition, understood epidemics, famine, natural disasters, and so on, as “problems” and improved society by solving those problems. However, contemporary problems with heightened levels of uncertainty have more complicated backgrounds, making it difficult to read and understand the causal relationships pertaining to these problems using scientific rationality alone.

On the other hand, if we look back on life in the pre-modern era, we find embedded ways of coping well with epidemics, disasters, and other of the inevitable dangers of life. Among the customs and traditional events in each region, one can find mechanisms for dealing with risk as a whole community, methods of maintaining communities, and ways to connect individuals with society and tradition. Furthermore, it becomes apparent that Nature and Society were not always divided in two. Thus we search for clues for coping with the seemingly insoluble problems of modernity by drawing on the social scientific theory of ANT, which tries to elucidate modern phenomena by reconsidering them as networks of things and people.
3. **On the Possibility of Incorporating ANT into Design Methodology**

Beginning in the 1980s, ANT spread widely as a theory for analyzing the formative processes of science and technology from a social scientific perspective. In ANT, not only human beings but also artifacts such as machinery, legal institutions, and organizations, as well as non-human entities in the natural environment are analyzed as having real agency. Actors' actions and cognition, interactions between actors, and the sum total of network effects are all described chronologically within their social context. It is good at criticizing the subject of analysis by seeing its network not as a fixed thing, but as an organic thing that changes with the negotiations and interactions among actors.

Although research incorporating ANT into the field of design is still relatively sparse, two broad trends can be distinguished. One is a group of research that attempts to incorporate ANT into the design research process. These studies, by treating subjects and situations both as actors for analysis, attempt to establish ANT as a method to achieve some insight that could not otherwise be had with traditional research methods. The other is a group of studies centered primarily in Scandinavian countries that incorporate ANT into the process of co-creation design. These two trends both draw heavily on the theoretical insights of STS and innovation studies. However, previous studies in these areas of design have limited their use of ANT to mere invocation of a name. Research that incorporates the “non-modern” critical viewpoint proposed by Latour to escape from modern values is not being done. Latour pointed out that in addition to the process of “translation,” there is a process of “purification” specific to modernity. He identified the source of the crisis of modernity in the existence of what he calls “hybrids,” gaps in the process of “purification” which separates human from objects and conceals the original state of the network (Latour 1993, pp. 10-11). Thus in reconsidering the dualism of society and nature, he suggests that it is important not to abandon modernity as a whole, but to prepare a balance sheet that inherits the best parts of modern and pre-modern times (Ibid. p.135).

4. **Case Studies of Pre-modern Customs using ANT**

4-1. **The Situation of Contemporary Tokyo Suburbia and the “Oinu-sama” Faith**

The object we analyze using ANT in this case is a community of indigenous beliefs affectionately referred to as “Oinu-sama.” This particular faith has its origins in a community in a municipal suburban area on the west side of Tokyo that focused on the *gofu*, or protective amulet (a token inscribed with the name or likeness of gods, the *gofu* is worn on the body or attached to walls to implore gods for protection from disasters).

“Oinu-sama” is, an honorific expression of a god in the form of a wolf. These are the contemporary remains of mountain worshipping creeds that revered the now-extinct Japanese wolf. In western Tokyo, it was practiced in the rural areas around the basin of the Tama River, which flows through the area, and centered on Musashi Mitake Shrine, located at the head of the river. The wolf that once lived in the mountains of Chichibu was revered as a god that protects agricultural crops from boars and so on. By receiving a wolf amulet from this shrine, it is said that the god's protection can be obtained, and from this a “kô” (a mutual help organization run by people with the same faith) was organized in various places. It was believed that by displaying the amulet in front of the door, one could obtain protection from theft and fire.
“Oinu-sama” is primarily practiced in the suburbs of Tokyo, which are bedroom towns developed to receive the workforce that concentrated in the city during the rapid economic growth of the 1960s. In the past, farmland and miscellaneous forest spread widely and the village had a small population, but now there are rows of elegant homes and commercial establishments packed with the latest, fashionable products at the station. In the process of development, pre-modern customs and blood relations gradually declined as new residents from all over Japan flowed into the area. In the course of urbanization, local events and rituals came to be seen as burdensome and were not continued. As a consequence, the living environment handed down from the Edo period completely changed in just a single generation. The “Oinu-sama” faith shared a similar fate; today it is a custom that is not commonly known. Depopulation due to aging and the outflow of population as people return to central Tokyo has become a big problem, especially since the 2000s. Under such circumstances, even though the numbers have decreased, “Oinu-sama” continues to be a living tradition. In the survey process, in addition to a literature survey (Ogura, 2011) on mountain faiths, we interviewed Sakata Seiichi, who inherited his local farm as well as the practice of the “Oinu-sama” faith. Sakata responded to the interview by explaining that he descends from a 400 year-old lineage of farmers that stretch back to the Edo era. He is remarkable in that, as a central figure in the town of Kurogane, Kanagawa prefecture, he still practices “Oinu-sama” today. (Figure1, 2)

Figure1: The amulets on the door of Sakata’s house
4-2. ANT Analysis of “Oinu-sama” Faith

Based on the interview, we will explain the actor-network of “Oinu-sama,” focusing on the situations in which amulets circulate (Figure 3). Amulets are printed by the chief priest of Mitake Shrine. The natural system symbolized by the wolf is engraved on the amulets, and amulets become agents for conveying faith. In winter, the priest descends the mountain and delivers amulets to people in the valley below. The recipient households belong to the “kōjū,” a religious organization rooted in the land. The “kōjū” is a very important unit as an actor that facilitates mutual aid during important ceremonial occasions, such as marriages and funerals. The chief priest performs a ritual prayer and offers a wooden amulet in front of each family's “kamidana” (a sacred shelf for keeping amulets, located in a permanent place in each house). This is the medium through which the god makes its entrance. Each household then donates as much as 300 yen (about 3 dollars) to the priest and buys as many amulets to hang outdoors as they will need. At this point, the amulet is an exchange good. For the recipients who hang the amulets on the door of their house, the signs give a sense of security by displaying the characters for “crime prevention” around the household. For Japanese farmers, the river and the mountain that is its water source are important actors that produce crops. It was thus natural for farmers to feel their presence in close proximity through amulets. Heads of households not only display amulets, they also deliver amulets to those closely related to the house, such as relatives. Even if those who receive the amulets do not understand the meaning symbolized by the amulets, they are nevertheless passively incorporated into the patriarchal
system centered on the Sakata family. In addition, in the past, there was also a “kōjū” that visited Musashi Mitake Shrine from a faraway place once a year. In that case travel expenses and votive donation were collected from each participant. Funds collected at this time were pooled, and it was possible for members of the “kō” to borrow some of that money. Thus, while “kōjū” was an organization based on natural beliefs, it also functioned as a bank, insurance, and mutual aid society. Then during the New Year’s festivities the amulets that have been hung throughout the year are burned in a rite conducted by the entire town. After that, the household purchases a new amulet from the visiting priest and the circle of the amulet network is closed.

From a modern perspective, an “amulet” is simply a magical charm, generally thought to have little or no relevance to or effect on our urban lives. However, through our ANT analysis we have shown how this amulet is a powerful actor that organizes and stabilizes a diversity of elements, such as information exchange between watershed farmlands, mutual aid between regions, connections between family and relatives, and the natural world with life in the municipal suburbs of Tokyo. Amulets are very functional things that negotiate various roles in a wide variety of contexts. Our consideration of amulets in the Tama River basin around Mt. Ontake reveals an alternative form community, one completely different from society in and around central Tokyo. Here we can see how Seiichi Sakata is living a double life: existing in both modern suburban society, and the network created through amulets.

On the other hand, while the network woven by the amulet is stable, it also proved to be a small network, stagnating from a lack of opportunities for new residents to enter (even if they express interest). Important ceremonial occasions like weddings and the rebuilding of houses, which were intimate parts of everyday life and opportunities to mobilize the network, have since been outsourced to external companies, eliminating the need for each resident to help out. The practices of amulets and the “kōjū” are on the steady path to decline. Likewise, for those newly migrating to the suburbs, there is no opportunity to become connected with the “gofu” amulet actors. Even though there is a critical awareness of the problems facing community, we also found that people are being cut off from opportunities to participate in forms of community like the amulet network.

Contemporary City Life

the Network of Contemporary Tokyo Suburbia
5. A Viewpoint Informed by our Analysis and New Design Methods

The above case study, in which we applied ANT analysis to design research, made it possible for us to understand what actors are involved in our complex urban life, how we are engaged in pre-modern customs, and to visualize and grasp what kind of meaning objects have in our lives. This design research method offers us a clue to the beginning of the kind of design appropriate to a complex modern age, with its unclear causal relationships, and suggests how it might be pursued effectively.

Drawing from the above research analysis as an example, we suggest that in order to best cope with contemporary problems, such as the isolation and spiritual devastation so common to suburban life, designers need to reconsider the importance of junction nodes like the “gofu” amulets, and pay close attention to their behavior as actors whose role changes in every interaction depending on its relationship within the amulet network. In other words, instead of adopting a design method that targets a specific problem directly and trying to solve the
problem by focusing only on the causal relationships directly connected to it, it is important to grasp the state of the entire actor network under consideration and stabilize the unstable network of actors that constitutes the problem group. By paying attention to the key actors in the network and working out the details, it becomes necessary to propose possible forms and configurations the network could take in the future.

Modern designers have to deal with clusters of complex problems. For that very reason, it is necessary to grasp the situation as the complex network it is, and moreover, to acquire a method to cope with it as a complex network. As we also saw in this case, actors who often play important roles as social junctions may well be seen as merely pre-modern customs and objects that are no longer necessary from the perspective of 20th century values. What we really want to emphasize here is the thing designers must pay attention to: like the “wolf amulets” it is “Real as Nature, narrated as Discourse, collective as Society, existential as Being (Latour 1993, p. 90)”; it is the action of the thing-as-actor; that is, the behavior itself.

Introduction of ANT analysis into design research leads to performing the activity of design from a worldview other than the “hybrid” state in which humans and goods are separate; that is, one other than the view Latour points to as the source of the modern crisis. To overcome the limitations of the “problem-solving”-type design methodology that modern designers so often take for granted, designers should draw on effective ANT analyses in their design research, treat humans and objects equally, and approach the act of design from a non-modern viewpoint. These are the preconditions for design, having fallen into a state of dysfunction, to put complicated social problems front and center, and once again play its social role.

6. Conclusion

Modern design has failed to find fundamental solutions to the various problems afflicting an increasingly reflexive and uncertain Risk Society, such as global environmental destruction, collapse of local communities, and so on. If modern design is to effectively address these problems, it is imperative that we reconsider the modern methods that design has relied on thus far. It was with an awareness of such problems that we, in this paper, incorporated ANT into design research and adopted the critical viewpoint of non-modernity as proposed by Latour to discuss the development of a new design methodology to replace the “problem-solving”-type methodologies and the simple model of causality that modern design is based on.

By analyzing the pre-modern “Oinu” faith in the suburbs of Tokyo using the analytical methods of ANT, which treats humans and objects equally and interprets the networks organized by them, we shed light on the presence of important actors, like “gofu” amulets, whose behavior shows us the importance of connecting people with nature, tradition, and community. This research methodology, which focuses on the existence of actors who can stabilize the network, is an effective method for approaching the networks of complex problems. With this method, it is possible to ascertain a role for contemporary designers as important actors who not only understand dynamic and complicated relationships but also participate in them. At the same time, the adoption of such a design method, one that attends to actors broadly understood to include humans and objects, also suggests the importance of departing from the human-centered design methodologies that currently define modernity.

Author Biography

Tomohide Mizuuchi
Tomohide Mizuuchi is an associate professor at the Design division, Department of the Arts, Nagoya University of the Arts. He holds a MA in Design Futures from Goldsmiths College and a Bachelor's degree in Science of Design from Musashino Art University in Japan. A specialist in the areas of Design theory, Design education and metadesign, he teaches design education from a comprehensive perspective including lifestyle design. Tomohide Mizuuchi has been driving various social design projects and research. He is also the Convener of a Foundation Design Program at Nagoya University of the Arts; a member of the Society of Science of Design, Japan.

Masako Miyata
Masako Miyata is an associate professor of the Department of Creation and Representation at Aichi Shukutoku University. She received a B.A. from Musashino Art University and a M.A. from the Graduate School of Interdisciplinary Information Studies, University of Tokyo. Her research interests include media design theory and practice. Miyata has been engaged in researches to analyze and support the process of emergent shape generation by non-professional people. She has been designing and facilitating workshops for citizen’s media expressions such as “Bibai Karuta (Japanese syllabary Card Game) Workshop” (2012-2013), “Bibai Design Project: Making a Regional Picnic” (2013), and “Telephonoscope Workshop” (2014-2016). Her Japanese publications include Media Literacy Training for University Students (2015). In 2014, Miyata collaborated with colleagues to launch the publication of the independent bilingual magazine 5: Designing Media Ecology. Since the first issue, she has been the designer of the magazine 5.

Ryuichi Nambu
Born in 1979. After graduating from ICU (International Christian University, Japan), obtained an MA at Goldsmiths College at the University of London. After returning to Japan, worked at Hiromura Design Office. As a graphic designer, works on a wide range of projects that include branding and signage design. After starting the independent design office in 2009, obtained an MA from the Graduate School of Interdisciplinary Information Studies, University of Tokyo. While there, took part in practical programs on media literacy as a designer. Launched ACTANT Inc., service design firm in Tokyo in 2013 and assumed role as its president. Member of the Japan Graphic Designers Association (JAGDA). Currently engaged in design that spans various touchpoints and is rooted in media studies and anthropology.
Systematizing Public Signage Systems for Smooth Urban Pedestrian Movement

YOSHITSUGU MORITA, Kyushu University, Fukuoka, JAPAN, morita@design.kyushu-u.ac.jp

HARUKA SOGABE, Kyushu University, Fukuoka, JAPAN, sogabe@design.kyushu-u.ac.jp

Abstract

While it is common for landscaped and well-marked urban streets to have sufficient identification signs, which display place or street names, they often face issues regarding the provision of information (e.g., in sign placement) and inadequate orientation signs, which play an indispensable role in facilitating pedestrian movement. Insufficient signage can be partially addressed by supplementing signs with non-informational urban elements, such as streetlights or other urban features that provide different sorts of information. In order to result in smooth urban pedestrian movement, public signage systems require a balance between districts and streets and a system for presenting linked information. This study proposes that an urban element design system can be applied to the construction of public signage systems for pedestrians. There are several methods by which to accomplish this; each fulfills the needs of different districts and streets. For example, some strategies suggest ways to integrate information in areas with many urban elements, such as public signage, while others offer strategies for adding pedestrian signs and other elements alongside vehicular signs in areas with insufficient information. This article proposes a distribution graph of public signage as a concrete method for organizing the construction of public signage. Such a distribution graph is a way to visualize different distributions of sign type, and see clusters of street patterns. It is an effective way not only to planning new pedestrian signage systems, but also for revising plans with biased or insufficient signage distribution.

Keywords: Public signage system, Public Design.

1. Aim and Methods

Japan has recently seen the implementation of pedestrian signage plans as a means of urban development. However, streets are lined with various signs not aimed at pedestrians, such as those for traffic control. This study focused on the distribution of public street signs by type and how they relate to street structure and nearby environments. The aim is to propose a method for constructing a pedestrian public sign system that supports the smooth movement of pedestrians in the city, including the use of public signs installed for control purposes.

I selected three major streets in downtown Fukuoka with similar specifications but different nearby environments and development situations. The distribution of public signs by type was surveyed on-site. Streets were divided into 14 sections, with intersections and installation roads within walking distance (ca. 100–200 m). I then analyzed the relation between the distribution of public signs by type and each section’s road structure and nearby environment. Public signs were categorized into three types: pedestrian, motorist, and dual (pedestrian and motorist). For the distribution quantities
by type, I quantified the number of signs (signs/100 m) to compare streets and sections.

Figure 1 Schematic diagram of surveyed streets

- Watanabe-dori: extension: 1,750 m; width: 50 m (sidewalk width: 10 m; 4 traffic lanes on each side); “Green Promenade” completed
- Taihaku-dori: extension: 1,994 m; width: 47–50 m (sidewalk width: 10 m; 4 traffic lanes on each side); “Symbol Road: Historical Promenade” completed
- Showa-dori: extension: 2,014 m; width: 36–50 m (sidewalk width: 6–10 m; 3–4 traffic lanes on each side); townscape development to be completed

2. Results

2.1. Distribution of All Information Types

Table 1 shows the types and average number of signs on the three streets.

</table>

The average number of signs for all information types on Watanabe-dori was 13.27 signs/100 m (5.62 pedestrian, 6.90 motorist, 0.76 dual). While there was a large distribution of pedestrian information in the downtown section around Tenjin (ca. 10 signs/100 m or more), surpassing that of motorist signs, it decreased (ca. 4 signs/100 m or more) when moving away from downtown. Motorist information had a fairly regular distribution (ca. 5 signs/100 m) across all segments.
On Taihaku-dori, the average number of signs for all information types was 13.22 signs/100 m (6.34 pedestrian, 5.73 motorist, 1.14 dual). The pedestrian average was higher than the motorist average, with both pedestrian and motorist signs tending to cluster around sections intersecting with major roads.

The average number of signs for all information types on Showa-dori was 12.29 signs/100 m (4.52 pedestrian, 6.97 motorist, 1.07 dual). There was a low distribution of pedestrian information, and motorist information was more prevalent in almost all segments. Distribution was especially high in segments S7–S10 close to Tenjin and in sections intersecting with major roads.
2.2. Distribution of Pedestrian Information

On Watanabe-dori, the types of pedestrian information concentrated around the Tenjin downtown area included geographic (ca. 2–7 signs/100 m), transportation (ca. 1–3 signs/100 m), and public (ca. 2 signs/100 m or less) information. Traffic and behavior management information tended to be concentrated in sections intersecting with major roads (ca. 4 signs/100 m).

On Taihaku-dori, geographic information was prevalent in sections T1–T6 (ca. 3–5 signs/100 m), while transportation and public information were extremely scarce (ca. 0.5 signs/100 m or less). Meanwhile, in the area between T7 and Hakata Station, geographic information decreased (ca. 1–2 signs/100 m) while transportation and public information increased.
On Showa-dori, the overall number of signs was low. Geographic (ca. 1–3 signs/100 m) and public transport (ca. 1–3 signs/100 m) information was concentrated in the Tenjin downtown area while a small number of public information signs were distributed in a few locations. Traffic and behavior management information signs tended to concentrate around intersections (ca. 3 signs/100 m).

Figure 3-3. Pedestrian sign distribution, Showa-dori (by section)

Figure 3 shows the distribution of pedestrian signs by section, excluding those limited to particular sections (e.g., information about taxis).

(1) Signs with Geographic Information for Pedestrians

On Watanabe-dori, the concentration of site identification signs has a significant effect on the Tenjin downtown area. Area and street signs on street lamps are especially numerous. Areas further away from downtown have less geographic information because of the scarcity of site identification information on street lamps. Orientation signs were evenly distributed, appearing only slightly more frequently in sections intersecting with major roads (ca. 0.5 signs/100 m).
Sections T1 and T6 of Taihaku-dori had a concentration of geographic information, consisting mostly of site identification signs, with street signs on street lamps comprising the majority. Meanwhile, there were no identification signs on street lamps beyond T7, halving the amount of geographic information in those areas. Orientation signs were concentrated in sections intersecting with major roads (ca. 1 sign/100 m).

Though the overall number of signs on Showa-dori was low, many were present in the S9 section in the Tenjin downtown area. Most site identification signs were address board distributed mostly evenly along the other two streets. Meanwhile, identification signs on street lamps and elsewhere were scarce. Orientation signs were only found between T1 and T9 (ca. 0.2–0.5 signs/100 m).
(2) Signs with Transportation Information for Pedestrians

Watanabe-dori has a concentration of public transportation, with a high distribution of transportation information—especially in the Tenjin downtown area—and bus stop signs in sections W2–W8 (0.6–1.5 signs/100 m). Taihaku-dori has subway stations, with a concentration of public information in the section intersecting with major roads (T6–T7, T10–T12) and a mostly even distribution of bus stop signs (ca. 0.2–1.0 signs/100 m). On Showa-dori, bus stop signs were fairly frequent around the Tenjin downtown area (ca. 1.5–2.5 signs/100 m) but were sparsely distributed in other sections. Taxi signs were distributed only in sections with designated taxi stops.

Figure 5-1. Pedestrian transportation information sign distribution, Watanabe-dori (by type)
(3) Signs with Traffic and Behavior Management Information for Pedestrians

On all three streets, pedestrian traffic lights (Watanabe-dori average: 1.56 signs/100 m; Taihaku-dori: 1.7 signs/100 m; Showa-dori: 1.68 signs/100 m) made up 50–80% of pedestrian control information (Watanabe-dori average: 2.45 signs/100 m; Taihaku-dori: 2.14 signs/100 m; Showa-dori: 2.11 signs/100 m). These were concentrated around intersections with major roads, as with traffic management signs. There was a high distribution of no-bicycle-parking signs around the Tenjin downtown areas of Watanabe-dori and Showa-dori (ca. 0.2–0.7 signs/100 m).
(4) Signs with Public Information for Pedestrians

Public information was concentrated (ca. 2 signs/100 m) in particular sections (e.g., friendship city guides around the Nishitetsu Fukuoka Station area of Watanabe-dori) or was mostly evenly distributed (ca. 0.2–0.7 signs/100 m) along historical promenades, such as Taihaku-dori, in the form of history-related signs.

2.3. Signs for Motorists

On all three streets, motorist information was concentrated in sections intersecting with major roads. Control information in particular tended to be concentrated in those sections (compared to other sections, they differed by ca. 5–8 signs/100 m). Geographic information was also somewhat highly distributed (ca. 1–2 signs/100 m) in sections intersecting with major roads, but they did not differ significantly from other sections.
(1) Signs with Geographic Information for Motorists

On all three streets, orientation signs were prevalent in sections intersecting with major roads (ca. 0.8–2 signs/100 m), with a high ratio of signs identifying important sites and a low ratio indicating directions (ca. 0.2 signs/100 m). Moreover, there was a high distribution (ca. 0.5 signs/100 m) of parking signs in the Tenjin downtown area, where there is a concentration of public parking spaces.

(2) Signs with Traffic and Behavior Management Information for Motorists

On all three streets, traffic control signs comprised more than 80% of traffic management information signs, concentrated in sections intersecting with major roads (ca. 4–8 signs/100 m along Watanabe-dori and Taihaku-dori; ca. 5.0–7.5 signs/100 m along the Nakasū–Tenjin section of Showa-dori). Motorist traffic lights were mostly evenly distributed (ca. 1.0–1.5 signs/100 m) along all three streets.
(3) Signs for Both Pedestrians and Motorists

Geographic information for both pedestrians and motorists mainly consisted of street name signs. On Taihaku-dori in particular, geographic information had a distribution of ca. 0.5–1.0 signs/100 m in all sections, meaning every other section. Similarly, the distribution in nine sections on Showa-dori was 0.2–1.0 signs/100 m. There were few directions to facilities. Dual traffic management information, such as pedestrian crossing signs, consisted mainly of pedestrian crossing signs for installation roads on all three streets. Fire hydrant signs comprised half of the dual information signs and had a distribution of ca. 0.2–1.0 signs/100 m on all streets.

Due to space limitations, graphs for pedestrian information and motorist management information relevant to the creation of a pedestrian public sign system can be found in Figures 4–7.

3. Method for Constructing a Pedestrian Public Sign System

3.1. Analysis and Discussion

(1) Effects of Townscape Development with Regard to Pedestrian Information

Compared to Showa-dori, whose townscape development was delayed, Watanabe-dori and Taihaku-dori had higher distributions of pedestrian information. This suggests that townscape development makes streets more suitable for pedestrian use. In particular, Taihaku-dori, which was developed as the Symbol Road of Fukuoka, systematically includes pedestrian information that considers pedestrian–motorist dual use and has a high level of organized motorist information.

(2) Possible Combined Use of Orientation and Site Identification Signs

Even streets with townscape development had a low distribution of orientation signs, which are important for pedestrian movement. In sections intersecting with major roads, there was one sign every 200 m. In other sections, the distance between signs was 450 m or greater, which exceeds the distance one can walk without feeling insecure (200 m).

Overall, there were not enough orientation signs. Even so, there was a high distribution of area and street name signs, the majority being attached to streetlamps and similar objects. In some places, there was one sign every 40 m (distance between streetlamps), indicating that the combined use of nonsign installations can effectively compensate for a lack of specialized signs. Therefore, we should also consider combined use with orientation signs.

(3) Possible Dual Use of Orientation and Other Public Signs

One possible way to compensate for the lack of orientation signs is the dual use of other public signs. Though pedestrian–motorist dual use signs were observed, they mainly consisted of street name and fire hydrant signs, and there was no dual use of orientation signs. Since there are already other public signs with similar distributional features placed around intersections and public transportation facilities (where people change movement behaviors), they could be dually used as orientation signs. Since public signs and orientation signs transmit information differently, an effective approach would be to aggregate, substitute, or equip existing signs rather than combine
them.
Public signs are concentrated around intersections. Thus, they can substitute for orientation signs with pedestrian traffic management information and motorist geographic information, be aggregated with motorist traffic management information signs, or be equipped with transportation information.

(4) Need to Consolidate Public Signage

Public signs are often concentrated in areas with many travelers, typically areas intersecting with major roads. For such sections with concentrations of a wide variety of public signs, signs should be consolidated beyond the immediate management area. Methods such as aggregation, substitution, combined use, and equipping can be useful for this purpose (Japan Society of Civil Engineers, 1985). [1]

3.2. Constructing a Pedestrian Public Sign System

Lines, levels, and nets are regarded as possible ways to configure new pedestrian public sign systems (Research Society on Community Design, 1993). For diverse and unpredictable movements in urban environments, however, a net configuration is ideal. This survey has clarified that budget and time constraints cause a limited number of signs to be placed in lines or levels. As such, a net configuration is proposed that involves the consolidation of public signs, as well as dual and combined use.

(1) Street Patterns and Distributional Features

When placing public signs in a general street plan, it can be difficult to detect whether certain types are too prevalent or too scarce. To remedy this, three street patterns (A–C) with differing public sign distributional features were derived from the survey results. A schema for urban organization was created by aggregating these street patterns with information on transportation facilities and local features. By entering the public sign distributions for each street pattern by type (dual information distributions are added to the respective pedestrian information distribution), we can designate public sign types for consolidation, dual use, or combined use based on their values. Figure 8 shows case studies from Showa-dori, whose pedestrian information is not yet completed. One section was selected for each of the three street patterns, showing the possibilities of aggregation, substitution, combined use, and equipping based on the survey results’ distribution values.
(2) Distribution Graph for Public Signs

The distribution graph for public signs visualizes the distribution values by type (Figure 9 uses the same street pattern case study data as above). This allows us to calculate the variable prediction value of the distributions by the designated consolidation method (aggregation, substitution, combined use, equipping) and by street pattern (straight arrow in Figure 9).

In case the variable prediction value is too low, as a rule we want there to be at least one sign every 200–300 m (safe walking distance). Pedestrian signs intended to orient pedestrians must provide information continuously as the pedestrian moves. They fulfill an especially important function by providing appropriate information at walkable intervals for those unfamiliar with the geography. For this study, we determined that the interval at which information is transmitted should be such that it can be conveniently walked. However, an actual pedestrian signage plan must determine a suitable interval based on local environmental features, street conditions, and how frequented the street is by locals and visitors.

Figure 9 shows a conceptual model for creating a pedestrian public sign system. The clockwise arrows signify the order of precedence for consolidation, taking into account what distance can be conveniently walked. The straight arrow represents the direction of consolidating existing public signs in case there is a need to compensate for a lack of orientation signs with pedestrian geographic information.
A pedestrian public sign system must be able to reduce public sign distribution imbalances for the sake of smooth pedestrian movement. Therefore, the aforementioned street pattern and public sign distribution graph must be combined with a consideration of actual urban organization, making adjustments to coordinate the plan with variable prediction values. When making adjustments, it is important to consider the potential implementation of dual and combined use, and to eliminate dispersions of variable prediction values in adjacent sections.

Furthermore, applying this method to a new pedestrian signage plan allows us to calculate the optimal locations and numbers of new signs needed to provide the required pedestrian orientation information. Thus, it facilitates the creation of a more effective pedestrian sign system.
4. Conclusion

This study surveyed differences in the distribution of public signs by type and used the results to identify problems. For example, despite the prevalence of public signs along urban streets (ca. 1 sign every 7.5 m), there is a lack of useful information for pedestrians, and the townscape seems unorganized. The study also evaluated whether newly installed pedestrian signs are actually effective. While there is a high distribution of pedestrian geographic information on systematically developed streets, the same is not true of undeveloped streets, highlighting the challenges of systematic street development.

There is a need, therefore, to reduce the current public sign distribution by street and local area, and develop a system that provides coordinated information. This study proposes the organizational method of informational urban environment installation as suitable for creating a new public sign system. Combining methods to accommodate area and street features is considered an effective way forward. For example, aggregation is suitable for organizing areas with a concentration of many structural elements. Meanwhile, the substitution, combined use, and equipping of motorist signs and other structural elements with pedestrian signs is suitable for areas that lack information. In particular, this study demonstrated the need to consolidate public signs—which comprise the majority of informational urban installations—to both secure pedestrian spaces and transmit accurate information.

References

Japan Society of Civil Engineers (Eds.). (1985). *Street Townscape Planning* (街路の景観設計) (Gihodo Books, 1985), p. 209. According to this source, aggregation means gathering multiple functionally related installations in one place and designing them as a unit. To substitute, combine, and equip means to use the installation’s original functional form and add another function. The relative importance for street use of the original function (A) and added function (B) can be expressed as substitution (A > B), combined use (A = B), and equipping (A < B), allowing for convenient classification.

Author Biography

Yoshitsugu Morita

Yoshitsugu Morita is a professor at the Faculty of Design, Kyushu University. He received a Ph.D. in 1999. Before he joined Kyushu University in 1992, he worked for GK Design Group Inc. in Japan as an Industrial Designer and Environmental Designer on projects ranging from public products (sign and street furniture) and public space (streetscape and bridge, etc.) to local branding. His areas of expertise are Industrial Design, Public Design, and Environmental Design.
Haruka Sogabe

Haruka Sogabe is an associate professor at the Faculty of Design, Kyushu University. She received a Ph.D. in 2009. She joined Kyushu University in 2009. Her areas of expertise are Industrial Design, Public Design, and Information Graphic Design.
Incorporating Co-Design Thinking to Understand Current and Future Experiences of Veterans in a University Environment

Joshua B. Morrow, The Ohio State University, Columbus, Ohio, morrow.129@buckeyemail.osu.edu

Abstract

The purpose of this research was to utilize co-design thinking to investigate and understand the experiences of veteran students entering into college at The Ohio State University (OSU) after military service, and to assist the university in improving those transition experiences. The research significance is that an increasing number of post-9/11 era veterans are utilizing the educational benefits earned through their service. Many of these service members have spent years inside a military culture, which has inadequately prepared them for a transition to the civilian and academic environments.

It has been found that veteran students often self-segregate due to age differences, and their experiences gained through military service. Additionally, while OSU’s Office of Military and Veteran Services (OMVS) has been doing incredible things to help veteran students transition away from the military and into OSU, many of their practices tend to promote self-segregation rather than integration.

Although it is not true across the entire population of veteran students, the research conducted showed that many sought opportunities for improved social integration programs. Opportunities lie in finding a balance between the culture that veteran students share, and integration into the civilian culture they are now part of. Additionally, veteran students could benefit from additional support in regards to academics and logistics when navigating through OSU.

The study conducted was comprised of preliminary interviews with a director of the OMVS, an initial survey, four co-design sessions with volunteer veteran students, and an evaluative survey to gain deeper insight into the possible new service concepts generated during the co-design sessions. Based on the research results, proposed new services and improvements to existing ones were presented to OSU’s OMVS.

Keywords: Co-Design Thinking, Veteran Students, Experience, Self-segregation, Integration,

Introduction

“Today’s veterans often come home to find that, although they’re willing to die for their country, they’re not sure how to live for it.” (Junger, 2016)

Today, veteran students make up roughly 4% of all college students in the U.S., and OSU has a veteran student population of around 2.19% of its roughly 66,046 students. It is amongst the smallest identified demographic at the university, but those numbers are only expected to increase as more and more service members return home from serving overseas and begin to
leave or retire from the military (Lackaye, 2011). Service members that have spent years deeply integrated into a culture that is very different from the day-to-day life of a student or a civilian, will be attempting to transition away from a military mindset and integrate into a larger, seemingly foreign, sociocultural environment. To be successful in the new culture that veteran students have willingly served and now chosen to be a part of, they will need help in adjusting to it. Studies have shown the ineffectiveness of the military to properly prepare and transition service members into civilian life (De Groat and Crowley, 2013), and since many of the veterans serving in this country’s most recent conflicts will be leaving service to attend higher education, the collegiate environment is the perfect opportunity to assist those veterans with their integration and future success in the civilian world.

The research that I have conducted has focused on understanding the experiences of veteran students entering into higher education at The Ohio State University for the first time after having served in the military, or, those that are returning to OSU after leaving the collegiate environment to serve in military operations. As part of the research methodology developed, Co-Design Thinking has been utilized in the engagement of current veteran students in order to let them guide the identification of new services, or improvements that can be applied to existing ones, with the goal of improving the transition and integration experiences of current and future veteran students.
Background and Literature Review

Through my own personal experience with the Army Reserves of having to leave twice during my design undergraduate degree, as well as observations and conversations with other veteran students, I observed that many veterans tended to self-segregate away from their civilian counterparts in the collegiate environment. I hypothesized, then, that this self-segregation of the veteran student community hindered the cultural integration of veteran students into the greater civilian populace, and therefore had a potentially negative impact on their success in pursuing civilian careers after college.

Although this hypothesis of veteran self-segregation was anecdotal, two academic papers validated my observations; the Doctoral Thesis of Brian Lackaye (2011) titled “In Country, On Campus: A Study of Combat Veteran Integration into Higher Education” and “Looking Critically at Reintegration of Post 9-11 Era Military Veterans” a white paper by Arthur S. De Groat and Richard P. Crowley (2013). These two studies point out both “that the tacit skills needed in civilian life tend to be under-developed in [veterans] as a result of their being institutionalized into the military sociocultural world” (De Groat and Crowley, 2013), as well as “[veteran student] identification with other veteran students was also a bi-product of their inability to identify with the greater student population.” (Lackaye, 2011)

Since many of the veterans serving in this country’s most recent conflicts have left or will be leaving service to attend higher education and take advantage of the benefits that they have earned, the collegiate environment is the perfect opportunity to assist those veterans with their integration and future success in the civilian world. However, veterans clearly face unique challenges that come with their separation from military service, challenges that are very foreign to collegiate faculty, staff, and policy makers, therefore, Co-design Thinking has been utilized, engaging veteran students in the collaborative design process as “experts of their own experience[s].” (Sanders and Stappers, 2016)
Based on the hypothesis of veteran student self-segregation at OSU, an iterative research plan was developed to dive deeper into their experiences and to better understand what veteran students thought and felt about transitioning into and through the collegiate environment. This plan consisted of four stages, each designed to build on the accumulated information gained by the stages that preceded it. The four stages of the methodology are described below.

**Phase 0: Preliminary Interviews**
Mike Forrest, a director of OSU’s Office of Military and Veteran Services (OMVS), was interviewed to develop a knowledge base of the offerings and operations of the OMVS. Additionally, any insights that he had in regards to the experiences of veteran students at OSU, and trends that he could identify in regard to areas of need for veteran students, were gathered. This information, along with insights from the literature review, was then used in order to inform the first phase of participant research.

**Phase 1: Initial Online Survey**
Phase 1 consisted of an online survey that was developed to gain a broad understanding of the thoughts of veteran students at OSU, including, for example, if and how they interacted with other students that were not veterans themselves, whether they belonged to any organizations or clubs, what did they think about the OMVS, and did they utilize any of the additional services that the OMVS offered. This survey was distributed via email to all undergraduate veteran students at OSU through the OMVS.

**Phase 2: Group Co-Design Sessions**
Phase 2 consisted of four co-design sessions that were designed based on the data collected from the first survey. In the co-design sessions, participants were first asked to reflect on how they perceived themselves in relation to no longer being in the military and then to create a timeline with a prepared toolkit of their experience thus far at OSU. After sharing their individual experience timelines, the participants were asked to collectively develop an “ideal” timeline for veteran students, transitioning into and through college at OSU after service, and then share what they had developed. The aggregate data from all of the co-design groups were then analyzed for key insights and opportunities that could be further developed. These insights were then utilized to prototype possible service solutions, in written format, that then created the basis for the third and final research phase.
Figure 3. Exercise 1. The first exercise of the co-design sessions asked the veteran student participants to reflect on how they consider themselves today: a veteran, a student, a veteran student, or a student veteran? They were then asked to link colored ribbon to “Who do they want to be?” a veteran, a civilian, a veteran civilian, or a civilian veteran? After all of the participants had completed this exercise, they were asked to share their individual thoughts, feelings and why they made the choices that they did.
Figure 4. Exercise 2. Participants worked with pre-designed and assembled exploratory tool kits to develop individual, current experience timelines of their transition into and through college after military service.
Figure 5. Exercise 2. A participant in the process of creating an experience map of their current college transition and integration experience.
Figure 6. Exercise 2. A participant’s current college transition and integration experience map.
Figure 7. Exercise 2. Participants sharing their individual, experience timelines with the rest of the group.

Figure 8. Exercise 3. Co-design participants working to map out an “ideal” experience for veteran students transitioning into and through the collegiate environment at OSU.
Figure 9. Exercise 3. Another group of participants working to co-design an “Ideal” experience map for future veteran students.
Phase 3: Evaluative Online Survey

The final phase of the research plan consisted of an online survey that was sent to OSU’s veteran student population and asked them to evaluate the desirability and validity of the prototype solutions. Based on the feedback generated through this phase, the prototype solutions were refined and developed into recommendations to be considered by the OMVS for implementation. This survey was distributed via email to all undergraduate veteran students at OSU through the OMVS just as the Phase 1 Survey was.
Discussion

I chose to conduct my research at OSU partially because it is a city in and of itself. It has its own distinct culture and has a rich diversity that has been created with students from around the country and around the world. It is also a place that someone can easily be lost in, can easily feel like just another name on a roster, another face in the crowd. It is a perfect analogy for a society, and therefore represents a relevant environment for looking into the transition and integration of veterans. OSU has tremendous support systems for all of its students, and in 2011 it made those support systems even greater when it opened its Office of Military and Veteran Services. This office is solely dedicated to helping veterans in their transition, and is in place to assist with their specific needs. Whether it be in helping veteran students to file the right paperwork in order to receive their VA benefits, or as a conduit for help in other areas that they may be having trouble with, the office is of tremendous service to the veteran student community.

As described in the first stage of my research methodology, Mike Forrest of OSU’s OMVS was interviewed to gain a better understanding of the office’s role, and the services that it offers to veteran students in its efforts to aid and facilitate their transition into and through college. Through these interviews with Mike, and with his help, I identified and mapped out the major touch points that nearly every veteran student experiences through the OMVS.
What I have come to call “the human element”, the individual *experience* and “overhaul of identity changes during transition” (De Groat and Crowley, 2013) began to emerge in the co-design sessions as an area worthy of further exploration in order to assist in the success of veteran students moving away from the military and into the civilian world. The loss of cultural identity that veterans feel when they leave service is well documented in Sebastian Junger’s *Tribe: On Homecoming and Belonging* and by Lackaye in his doctoral thesis, and to transition to an institution as large as OSU can be daunting. And while the OMVS does a tremendous job of helping veteran students enter into and traverse through OSU, it does so in an expected fashion for an institution of its size, that is to say, mechanically.

Inarguably, every resource and opportunity for success is available to all students at OSU, and the OMVS stands at the front of the pack for the resources and support that it offers veterans as compared to many other colleges and universities that I have studied. But as mentioned previously, my research indicated that *the human element*, the sociocultural integration of veteran students, was not being thoroughly addressed. Yes, the OMVS does organize events for veteran students, but most of those are for veteran students with other veteran students, or, often for veterans to be recognized for their service at venues such as sporting events. And although Mike Forrest said that veteran students were encouraged to move outside of veteran sociocultural circles and get involved in extracurricular activities, no services or programs seemed to be in place to assist in this facet of transition and integration. In fact, a look at the planned calendar of events for the 2016/2017 academic year only shows veteran only, or veteran focused, events. Periodically, tickets or available spaces to OSU and non-OSU events will be given out to veteran...
students on a first come first serve basis through the OMVS, but these events are not something that the OMVS has specifically organized for veteran students.

Figure 14. A screen capture of the OMVS events calendar through the spring of 2017.
The data collected from the Phase 1 survey helped to develop the co-design process and materials that were used by the veteran student participants during the Phase 2 workshops. During all four of the co-design workshops, many of the participants expressed similar high and low points in regards to their current experiences at OSU, and additionally, each group identified possible solutions to similar areas of unmet needs that were addressed in their collaboratively developed “ideal” college timelines.

After analyzing the aggregate of data from the co-design workshops, a list of 22 possible services were identified for evaluation through the Phase 3 survey. And while some of these services did focus on more “technical” solutions that the participants would like to see implemented by the OMVS, such as “Classes (for credit) to help with developing academic skills,” “Assistance with academic and career goal setting,” or “An ‘exit program’ to assist with transitioning out of college,” many of the service solutions identified by the participants addressed the sociocultural disconnect that veteran students often feel in regards to their experience at college. The list of identified solutions that addressed veteran student sociocultural integration that was developed by the co-design participants is as follows:

- Improved “Re-entry” support for Guard and Reserve students returning from being called to service
- Veteran study groups
- Upper level veteran mentors “buddies” for new veteran students
- Being paired with an upperclassman in their degree field (veteran or civilian)
- Mentoring (through a TA position) new veteran students
- Increased access to, and availability of, counseling services
- Purposefully organized veteran & civilian social events
- OMVS organized events to become involved with groups or organizations outside of OSU
- An organized support group for family members of veteran students
- More daytime social events
- Increased outreach from veteran students/veteran student groups (Vets 4 Vets, etc.) to new veteran students

Figure 15. A list of solutions identified by the co-design participants addressing veteran student sociocultural integration.

In Phase 3, an evaluative survey was sent out to OSU’s veteran student population giving them the opportunity to evaluate the 22 possible service solutions. The service solutions listed above were responded to positively, with most participants indicating that they were “somewhat interested” to “very interested” in the proposed solutions. These service solutions indicate a strong desire for an improved sociocultural transition and integration experience by veteran
students at OSU that has yet to be fulfilled by any current services, or isn’t known about by the participants, indicating a need for greater publicity of any said services. Conversely, some of the desired service solutions seem to perpetuate veteran student self-segregation, such as veteran mentors for new veteran students. But this is not the only interpretation. Lackaye developed a theoretical framework of veteran student integration where because of “the notion of a ‘shared experience’ amongst veterans… the need for these individuals to connect with others they can relate to is an essential first step” (Lackye, 2011) in their transition and integration before moving into an experience of greater sociocultural involvement in the collegiate environment as a whole.

**Conclusion**

Through the use of Co-Design Thinking, a detailed and thorough investigation of the current experiences of veteran students at The Ohio State University, in addition to an exploration of what they feel may be an ideal experience over the course of a collegiate career for future veteran students, has been carried out. The use of co-design as a research approach, and the iterative research methodology that was developed, has allowed for an authentic investigation into the thoughts and feelings that veteran students experience, revealing the human and interpersonal issues that matter as they transition out of the culture and mindset of a service member, into that of a student, and then through their collegiate career. The utilization of the co-design process helped the participants to identify, define and express the positive and negative experiences with transitioning into and through OSU, indicating successful services that OSU and the OMVS has in place for them to utilize, as well as drawing attention to areas of unmet needs. Additionally, the research participants were able to collectively generate suggestions for possible solutions to the pain points and areas of unmet needs that they had identified.

Additionally, I’d like to comment on two aspects of the co-design sessions that, although they are not radically surprising, were unexpected. The first aspect was the sense of catharsis that all of the participants, and myself, seemed to experience by participating in such a collaborative manner with people with which we had a commonality. As I have mentioned, the loss of cultural identity for veterans is well documented and can be an extremely distressing experience. However, working collaboratively and sharing both positive and negative experiences as veteran students before working together to address those issues served as an expressive outlet, with nearly all of the participants commenting spontaneously on how much they enjoyed the co-design sessions and how, through the exercises, they were provided an opportunity to reflect on their experiences. It also became clear that the use of co-design sessions could provide a valuable tool for veteran students to explore and exercise introspection in regards to their current experiences, their goals while in college, and their desires for the future. With this being said, the use of co-design sessions, or a variant thereof, is suggested for development and implementation by OSU’s OMVS as a service to help new veteran students in their transition into the collegiate environment, for academic exploration, and to assist in creating a “roadmap” toward the completion of their degree.

The difficulty that veterans often experience when separating from military service, or, returning home from service overseas, as is the case of the National Guard and Reserves, is one that is extremely complex with no easily identifiable solution. Many of the sources of this difficulty are
systemic to the nature and culture of military service, and, in being so, would require research, service development and implementation on a scale and scope much larger than I was able to carry out through this project. Additionally, solutions to the transitional difficulty that veterans face would seemingly be best developed and implemented at a stage prior to their separation from the military, and in this case, transition into a college environment. However, as indicated through the literary research, interviews, co-design sessions, and evaluative surveys, services at OSU can be implemented or improved upon which would help to ease the transition and integration experience for veteran students through new sociocultural integration initiatives, as well as ones that address the more “logistical” experiences of veteran students.

Author Biography

Joshua B. Morrow

Josh Morrow served in the U.S. Army Reserves from 2000 until 2011, with one stateside support deployment in 2002 and a deployment to Iraq in 2004-2005, both of which required him to pause his pursuit of a BSD in Industrial Design from The Ohio State University. In 2008 he received his baccalaureate degree from OSU, but was soon deployed to Afghanistan in 2009-2010. In 2011, Josh chose to leave the military to focus on his career in design research, working as a researcher at Karten Design before returning to Columbus, OH in 2012 to work in a freelance capacity.

Now completing his MFA in Design Research and Development at OSU, Josh’s combined experiences of design research and military service have allowed him to develop a deep passion for working with people across the globe and to develop innovative solutions, services, and strategies through insight, empathy and creativity. Looking toward the future, Josh hopes to work in a capacity of service to others through the application of Co-Design Thinking at home and abroad.
Service Design as a Way to Engage Communities

Pamela Napier, Assistant Professor, Visual Communication Department, Indiana University – Herron School of Art and Design, Indianapolis, Indiana, USA, pcnapier@iupui.edu

Terri Wada, President & Design Strategist, Collabo Creative LLC, Indianapolis, Indiana, USA, terri@collabocreative.com

Abstract

In an equally distressed and burgeoning community just outside of our major metropolitan city, there is a history of transformation efforts—from creative placemaking, to affordable housing initiatives, to economic re-development—which have all seemed to fall short in the area of community engagement.

From the creation of neighborhood festivals that have low resident turnout, to a backlash of discouraged citizens who feel unheard and uninformed, there was a need to re-consider how to involve this unique community—made up of four very distinct neighborhoods—in the imminent re-development of the area in which they live.

In the winter of 2016, our service design and creative strategy consultancy was brought in to a city-wide visionary community development project tied to our rapidly approaching bicentennial, in order to utilize service design methodologies as a way to engage communities and to design with organizations and community residents according to their needs and desires.

This short paper will highlight a case study of an ongoing collaboration between our consultancy; a non-profit organization dedicated to the growth of it’s community; a higher-education institution with a legacy of community engagement; a local office of the country’s largest community development corporation focused on Creative Placemaking and community revitalization; and, most importantly, various residents and stakeholders.

The accompanying poster will visualize the process of engagement of various community stakeholders, tailored design research methods, and mechanisms for assessing short- and long-term community impact.

Community Engagement, Design Research, Service Design, Participatory Design, Creative Placemaking
Introduction

Walkability. Public art. Vibrant commercial and community activity. These are some of the many calling cards of great places in great cities. Great Places 2020 is a visionary community development project to transform strategic places in Marion County—located in Indianapolis, Indiana, USA—into dynamic centers of culture, commerce and community. Through a partnership with Local Initiatives Support Coalition (LISC) Indianapolis, and Indiana University-Purdue University Indianapolis (IUPUI), part of this Great Places initiative centers around the notion of “creative placemaking.”

With a specific focus on the River West Great Place, our service design and design strategy consultancy, Collabo Creative, was brought in to work collaboratively with Big Car Collaborative—a nonprofit arts organization and collective of artist focused on creative placemaking and socially engaged art—and Indy Convergence—a nonprofit Indianapolis arts organization dedicated to the growth of artists, located in the epicenter of River West—to engage with residents in this close-knit community.

Collabo was engaged specifically to lead resident engagement and participation in order to improve the current, as well as inform the new development of community programming. This research prioritized resident inclusion in shaping a neighborhood festival named “Near West Flow Fest: A Block Party on West Michigan Street,” as well as other community-vetted programming, including an “Art Walk” series and “Portrait Project,” which were developed and put on by Indy Convergence.

Working closely with Indy Convergence, Collabo carried out a 5-month engagement strategy that included strategic planning meetings, planning and facilitation of multiple engagement events, "pop-up" community listening sessions, and 1-on-1 interviews.

As defined by LISC, creative placemaking is seen as: People coming together to make positive physical, economic and social impacts in their neighborhood through art, culture and creativity. LISC invests in creative placemaking to help people and places prosper by advancing arts- and cultural-based strategies in comprehensive community development. Specifically, LISC creative placemaking work seeks to accelerate traditional community development outcomes in low-income neighborhoods and communities of color including: Community cultural development, Physical Transformation, and Economic Benefits. Their work is informed by six guiding principles: 1. Artists as leaders; 2. Racial Equity; 3. Development without displacement; 4. Community-driven, comprehensive, collaborative; 5. Building Capacity; and 6. Escape Velocity.

Based on our practice and knowledge in People-Centered Design (or the more well-known of “Human-Centered” Design) and Service Design, involving neighborhood residents in the shaping or reshaping of programs and the touchpoints that create those services seemed apparent and imperative. According to Service Design Network—a global platform dedicated to strengthening the growing discipline of Service Design—Service Design is the activity of planning and organizing people, infrastructure, communication and material components of a service in order to improve its quality and the interaction between service provider and customers. The purpose of service design methodologies is
to design according to the needs of customers or participants, so that the service is user-friendly, competitive and relevant to the customers.

Given this definition, we understand that the notion of a service expands beyond the service itself, and instead explores a balance and blending between the actions carried out by providers with the behaviors and desires of users, customers, or in our case—participants. Service Design, in the service of engaging communities, seems to be a perfect fit when we consider the want for creative placemaking under the guise of LISC’s definition.

**Approach and Methodology**

Collabo’s work within the River West and Near West communities used LISC’s Guiding Principles for creative placemaking to help guide their people-centered approach in the following ways: 1. Working collaboratively with Indy Convergence and their “Artist Corps,” looking to them as artists as leaders who are leading transformation in their communities, and collaboratively hosting events and resident recruitment; 2. Focusing on racial equity, by seeking out residents who represent people of color and others historically marginalized in order to enable them to be at the center of transforming their lives and communities; 3. Efforts made in creating communication materials and using culture-based approaches that allow residents to identify and celebrate their neighborhood as their own in order to encourage development without displacement; 4. Using methods and activities that were community-driven, comprehensive and collaborative, placing the highest priority on uncovering and communicating the hopes, dreams and desires of the residents, while working collaboratively with local organizations and businesses; 5. Placing focus on engagement efforts that are driven by building capacity within the community—enabling residents to communicate their vision for how they want to improve their community, and providing the tools and opportunities for them to express their vision in a collaborative way; and 6. Helping key partner organizations look to the future in order to have enough escape velocity to embed creative placemaking in their core work, by engaging residents in the conceptual planning of opportunities for future community-driven programming.

People-Centered Design is Collabo’s approach and methodology to creating innovative solutions through focus on designing with people, rather than for people. This approach combines a process that utilizes Design Thinking and Participatory Design Research methods in order to empower the people who ultimately use a product, service, or system—along with those who have the most to gain or lose—to collaboratively create positive impact and innovation. And by ‘people’ we mean users, customers, stakeholders—the actual people involved in the initial problem or challenge. It is this ‘bottom-up’ approach that is inclusive and participatory, to help people: Communicate their experiences, in order to frame root—or core—problems, and collaboratively create meaningful impact through solutions developed by the very people who will use or implement them.
Resident Engagement/Design Research Methods

Resident engagement methods were focused on further developing and supporting current community programming in River West, including the “Near West Flow Fest: A Block Party on West Michigan Street”, as well as other community-vetted programming, including the “Art Walk” and “Portrait Project,” developed and put on by Indy Convergence. The focus for these methods was to go to residents and meet them “where they were,” selecting specific locations at optimal timeframes for resident input and engagement. In addition, as a way to start to explore and shape potential future community-driven programming and events in this community, methods also included inviting residents to participate in 1-on-1 interviews and engaging them in activities that allowed them to share their daily lives and rituals.

Resident engagement methods included: 1) Hosting the “River West Street Festival Kickoff Party.” This included canvassing the River West community and surrounding neighborhoods to gather information and invite residents—whether they had volunteered at the previous festival or not—to celebrate their successes and share their challenges of the last year’s festival; 2) Engaging residents at the first annual “Art Walk,” which included creating tools and probes to enable people to share their thoughts and ideas for creating resident- and community-driven programming; 3) Facilitating multiple
“Community Outreach Pop-up Sessions,” including using tools and prompts that asked residents (specifically youth and minorities) to share their ideas and challenges with the previous festival; and 4) Conducting 1-on-1 Resident Interviews, which allowed for deeper discussion around exploring daily routines, hopes and desires of both short- and long-term residents.

Resident Recruitment

Working closely with Indy Convergence and their Artist Corps, Collabo created a series of recruitment tools. These tools served three objectives: 1. To gather information from residents to understand how they prefer to obtain information, both from a broad perspective, as well as community-focused; 2. To invite residents to the “Near West Flow Fest” (formerly called the “River West Street Festival”), as a way to celebrate past volunteers’ successes, and elicit volunteers for the 2017 festival; and 3. To enable residents to share their contact information to receive news and updates about other events and engagements, as well as getting involved in the planning for the 2017 festival. Indy Convergence and their Artist Corps canvassed the neighborhood and surrounding areas with these tools by going door-to-door and delivering the invitation, as well as asking the questions on the prompt sheet.

Figure 2: Recruitment Tools
River West Street Festival Kickoff Party

Indy Convergence (IC) was in need of not only understanding what the community’s perception was of the previous year’s festival (formerly called the “West Michigan Street Festival”), but also needed a way to begin to uncover their thoughts and ideas surrounding new programs/events/initiatives that IC could help shape. In April 2017, Indy Convergence and Collabo hosted the “River West Street Festival Kickoff Party.” Collabo worked closely with IC to design the engagement and developed participatory activities that were centered around not only gaining information and opinions around the previous and future festival, but also enabling them to generate ideas for future programming that they would like to see in their community, and give input on existing projects that IC was currently developing. The party was designed to be a “drop-in” event, where residents could come and go as they pleased, enjoy beverages and other refreshments, and engage with the activities, as well as each other.

Figure 3: Kickoff Party
Art Walk and Portrait Project

Indy Convergence was in need of gathering input for not only the development of future “Art Walks” (interactive art walks in River West which included new art work displayed in their gallery, live music in the Art Alley, and refreshments), but also for informing the “Portrait Project,” using recorded interviews and collected stories from residents about their neighborhood, which would then be given to a local artist to use as inspiration for a new work of art, to be displayed at Indy Convergence during events and later in a more permanent location. The portraits would be synced with the actual interviews with a QR code so the stories and artwork could be experienced at the same time. For Indy Convergence's first of four Art Walks, Collabo created probes and tools to engage with the Art Walk visitors to share stories and suggestions for people to include in the Portrait Project, as well as envisioning what future Art Walks could include and look like.

Figure 3: Kickoff Party

Community Outreach Pop-up Sessions

In an effort to not only engage more youth in the shaping of the future festival, but also residents who represent people of color and others historically marginalized, Collabo developed a series of “Community Outreach Pop-up Sessions” at three key locations for residents in the Near West. These engagements were designed in such a way to enable both youth and adults to respond to a series of prompts around understanding their perceptions of last years’ festival, as well as gathering ideas for the future festival.
Resident Interviews

In order to gain a better understanding of people’s daily behaviors within the community, Collabo conducted 1-on-1 interviews with a diverse group of people in the Near West. Criteria for recruiting participants required that they were either living or working (or both) in this area. The main objectives of the interviews were to dig deeper into the residents’ daily activities, and their thoughts and feelings about the area where they live. Each interview lasted less than 1 hour, during which two maps were generated as visual prompts to enable participants to map out daily routines and frequent places visited. Participants used stickers with visual icons to represent activities and places as they mapped out a narrative of their daily routines, and were provided with gift cards as incentives for their time. Questions and prompts focused on using the map as a visual tool to discuss daily activities and behaviors as they aligned with key locations in their community, uncovering insights into how the residents felt about their community, and describing challenges in their daily lives within their community.
Data Analysis and Key Findings

All of the data sets collected through each of the community engagement methods were analyzed, grouped, and interpreted within each of the focus areas: Near West/River West Street Festival, Art Walk & Portrait Project ideas, and Community Creative Placemaking.

![Image: Data Analysis](image)

Figure 7: Data Analysis

From the combined engagements focusing on the Street Festival (the “Kickoff Party,” and the “Community Outreach Pop-up Sessions” at three key locations in the Near West), three main components were uncovered through the process of analysis: the environment, the activities, and the advertisement. Data collected was broken down into folks that participated last year, and folks that didn't participate last year, with common categories in each focusing on what people liked, what they would change, and what they would like to experience in the next festival.

The categories of experiences then led to a synthesis of common areas identified, as well as new ideas to explore for the festival, and ideas for how the community could become involved and take more ownership of the overall festival experience.
From the activities and engagement during Indy Convergence’s first Art Walk, which focused on generating ideas for future Art Walks, as well as ideas for the Portrait Project, two key themes emerged during data analysis: Environment & Atmosphere, and Art Experience & Activities. A data map and transcription of the findings were presented and delivered to Indy Convergence, which they were able to use in subsequent meetings and recruitment for participants. From the 1-on-1 interviews, personas were created to represent sub-sets of Near West/River West residents: Long-Term and Short-Term Residents. Based on the insights gained through this research we were able to frame in on key opportunity areas, two of which would align well with creative placemaking efforts:

1. Holistic or Integrated Family Programming
2. Environment/Beautification of abandoned & neglected homes
Figure 9: Placemaking Synthesis Map
Discussion

One key takeaway within this research, has been the consideration of cultural behaviors in conducting community research. Within the context of this project, a key focus has been on needing to “meet people where they’re at,” and even before being able to go where they are in order to engage with them, you must be able to know where they frequent, and why. We also found that there was an increased need for rich, “quick-touch” engagements, that were not too time-consuming and easily enabled people to express themselves. As this paper is being written, we are still working through the process of assessing engagement, impact, and community capacity.

Conclusion

The next steps in this particular project, would be to generate community-driven ideas for future creative placemaking initiatives within these specific areas. If possible, participatory or generative sessions with Near West/River West residents would be ideal to get actual residents’ input for future initiatives. Additionally, further research is necessary to understand why local, cultural businesses are (according to residents) on the decline within the Near West/River West area.
Moving graphic design forward with service design methods: Diversifying the role of graphic design among small local industry projects
Erica Ormsby PhD Student Perth Australia edormsby@our.ecu.edu.au

Abstract

The field of graphic design has continually evolved to encompass a wide scope of skills. From designing graphics to designing business strategies, graphic designers can be incorporated into all stages of industry projects. For some graphic designers around the world, broad uses of design practices are recognised as significant and are being applied to a breadth of large-scale business and community sector frameworks. However, these skills are frequently under-utilised and their value overlooked among small business projects. Perth-based design jobs, for example, are commonly outcome-driven and graphic designers are typically hired by clients at the end stage of business projects to only make project artefacts such as websites, business cards or brochures. Gjoko Muratovski, Director of The Myron E. Ullman, Jr. School of Design at DAAP, University of Cincinnati, puts forth that big businesses has benefitted greatly from integrating design’s intrinsic methods into all aspects of product and service development. In his paper titled Paradigm Shift: Report on the New Role of Design in Business and Society he states that “With the growing reputation of design as a catalyst for business innovation, designers are being invited to take on executive roles. Jonathan Ive (Apple, Inc.), Mark Parker (Nike, Inc.), David Butler (The Coca-Cola Company), and Todd Simmons (IBM Corporation) are perhaps the most notable examples of this emerging trend” (2015, p. 121). Literary statements such as this one, depict the rise of design using corporate giants as example. A discussion about the expansion of design amongst smaller business sectors, however, appears to be lacking. This report looks to explore this as the broad idea of my PhD. My paper views that there is gap in Perth local graphic design profession – graphic designers are not engaging with broader and more holistic design strategies such as those employed in service design. As part of my PhD project, this paper will discuss the literature review, research methods and design philosophy relevant to design strategies and processes used in graphic designers in Perth.

Keywords

Graphic Design, Service Design, Small Business, Holistic, Community-focused, Innovation
Introduction

Design theorists, such as Tim Brown and Barry Katz (2011) claim in their article, “Change by Design”, that “the inherent scalability of design thinking has led us to invent new and radical forms of collaboration that blur the boundaries between creators and consumers” (p. 382). This statement alone depicts the extreme upheaval of existing graphic design practices already occurring among globally established design firms. There is little evidence to suggest, however, that the graphic design industry in Perth, Western Australia, is engaging in a similarly dramatic shift in design practice. Therefore, the need for inquiry into the potential effects of this upon design practices within the local design community is timely. Service design methods, which are commonly applied to expansive community-focused service systems via a holistic interdisciplinary approach, are one way to diversify graphic design skills beyond the production of ephemeral objects. My research looks to explore how service design methods might expand roles for graphic designers and their significance within smaller industry frameworks. The literature review for this paper will be incorporated into the body of this document.

My PhD study looks to incorporate case studies, practice-based and practice-led research methods to investigate two small graphic design firms who offer differing design services in Perth, Western Australia. The aim of this research is to investigate the responses of graphic designers and also local industry following the introduction of service design approaches to small commercial graphic design projects in Perth, Western Australia. Service design, unlike traditional graphic design practices which are still typical in Perth, is not focused on artefacts. Stickdorn & Schneider (2011) assert that, “The approach of service design refers to the process of design rather than its outcome” (p. 14). They state that design needs to consider the larger picture when considering design issues (which are predominantly presented as client requests for artefacts) and propose that “the outcome of service design process can have various forms: rather abstract organisational structures, operation processes, service experiences and even concrete physical objects” (p. 14).

The Complexities of the Significance of Design

Graphic designers have contributed to some of the most significant design outcomes in history, books being just one example. Graphic design is in almost every moment of every day for people living in modern societies around the world. It is in the traffic signage systems which allow for safe travel on busy roads or in the instructions on drug packaging helping patients safely take medicines, and in more recent times, constantly to hand as we operate applications on our mobile phones. Williams (2010) notes that, “Never before has graphic design been so prominent in our everyday activities. People rely on good graphics regularly to select navigation on web sites, create support for their presentations, validate their investments via charts, etc. The significance of what we do is at the very center of many people’s daily lives” (p. 179). The skills used to create these graphic design outcomes are however often overlooked, and acknowledgement of the value and authenticity of graphic design concepts has been lost. The specialised skills used to make original graphic designs can extend to all aspects of community-based problems. This approach can bring unique design results to broad societal issues but an extension of graphic design services in this way is often under-utilised. The reasons for graphic design’s loss of recognition for wider uses of its unique skill-set are
complex. Graphic designers today therefore are faced with the following complexities:

- **Discrete problems to complex social problems:** Graphic designers used to tackle discrete branding problems such as designing corporate identities. However, the current situation requires designers to engage in all stages of the development of multifaceted design strategies to innovate organisational operations for corporate or social institutions.
- **Graphic designers are no longer paid for technical skills alone:** Complex social problems require designers to think beyond operating design softwares that are currently more intuitive for non-designers to operate. Designers’ roles are now to explore complex problems using broader design skills such as design thinking to reach holistic, community-focused outcomes.

### The Evolving Field of Graphic Design: Expanding Graphic Design Beyond Ephemera

The term ‘graphic design’ was first used in 1922 by American type designer, William Addison Dwiggins (Meggs, 1998). Since then this design field has continuously adapted the way in which it has worked. The gradual refinement of graphic design practices and incorporation of new skills was necessary to successfully transition through major changes within this discipline over time. During the 1980’s for example, advances in technology among media communications thrust game-changing production tools upon graphic designers in the form of computers and software platforms. “Technology transformed the era of mass communications aimed toward mass audiences into a period of decentralised media offering hundreds of options” (Meggs, 1998, p. 455). This radical new way of working resulted in graphic design absorbing additional media practices into its field, such as typesetting, photographic manipulation and even video editing. The results of which, are an expansion of communication skills and creative methods, which can be applied to myriad design projects across a wide range of industries.

The discipline of graphic design however, particularly in recent times, has struggled to vocalize how integral its creative methodology is and how wide ranging its use can be. From my viewpoint, one of the key issues underpinning why graphic designers are not employed to serve in broader creative roles is that their design practices, particularly in Perth, seem to be limited to ephemera. Graphic design has assisted in forming iconic global identities for fast food giant, McDonalds, or computer heavyweight, Apple Inc. These companies fiercely protect their graphic emblems through trademarks, patents and swift legal action. Yet significant value in the graphic design methods, which brought universal recognition to these large company identities, is often overlooked. The pinnacle of graphic design appears to be about establishing and protecting corporate identity in order to gain brand recognition and subsequently push product units. In Perth, from my experience, this is often what happens in most graphic design contexts. However, in other parts of the world, it is becoming apparent that graphic design has a larger role to play.

Urban designers, in Perth for example, are connected with creating interactive human spaces within our cities and towns promoting designers, instead, seem to be linked only with artefacts
for commercial uses. Examples include graphics for promotional needs such as flyers, websites, brochures and logos or graphics for sellable items such as “cat food, stomach powders, detergent, hair restorer, striped toothpaste, aftershave lotion, before shave lotion, slimming diets, fattening diets, deodorant fizzy water, cigarettes, roll-ons, pull-ons and slip-ons” (Garland, 1964, p. 159). Some graphic designers within the commercial sector of Perth, however, are aligned with the perspective that graphic designers are too focused only on the design of ephemera. They consider that the local industry is behind current international trends with regards to its artefact driven view of graphic design. Perth is a small to medium sized, affluent western city, but geographically isolated. It can be a late adopter of business and design methods. Perth design authors, Kueh, Medley & Price (2013), declare that “while this focus is already a norm in many countries, the current design direction in Western Australia is still very much focusing on aesthetic, retail and object outcomes” (p. 2).

Tim Brown (2009) of IDEO presented a TED Talk at Oxford University in England in 2009 to discuss the evolution of design and stated, “this small view of design is a relatively recent phenomena and in fact only really emerged in the latter half of the 20th century as design became a tool of consumerism”. He envisages “that if we take a different view of design and focus less on the object and more on design thinking as an approach that we actually might see the result in a bigger impact”. Brown (2009) expanded on this idea during his presentation to declare that design used to be big, it then became small and it is now becoming big again thanks to an unfolding of design fields such as design thinking and service design. He has since put forth that businesses will benefit greatly from integrating graphic design’s intrinsic methods into all aspects of product and service development instead of enlisting “designers to make an already developed idea more attractive” (Brown & Katz, 2011, p. 381).

**An Evaluation of Design in Varying Contexts**

Design within a global context is already being used extensively for broad applications. Design methods typical of design fields such as Graphic Design, Product Design, Service Design, Social Design, UX Design and even emerging design fields, such as Circular Design are being used by big business to assist in generating large-scale project innovations. Over the past twenty years, corporate giants such as Coca-Cola, Apple, Nike and IBM, to name just a few, have rapidly expanded their uses for design beyond the development of products and communications. Archetypical international companies such as these have integrated design into all aspects of their business and other large corporations are following suit:

More and more designers are now getting involved with business development and growth. This entrepreneurial spirit marks a new era for both design and business. Going beyond design of products, spaces and communications, designers have ventured into a new field - design of businesses. With the growing reputation of design as a catalyst for business innovation, designers are being invited to take on executive roles. (Muratovski, 2015, p. 121)
Design is proving to be a powerful force among big business and the positive results are being assessed; “The Design Value Index (DVI), a market capitalization-weighted index comprised of design-driven companies” (Rae, 2015), estimates that “the value of design beat the S&P, an American stock market index, by 228% over the past 10 years” (Rae, 2014):

The 2014 Design Value Index shows us for a second year that corporations that put an emphasis on design as a strategic asset perform significantly better than those that do not. As corporate design capabilities mature, executives are able to direct this power towards their companies’ most challenging problems. This, in turn, allows design-driven companies to grow faster, and often with higher margins, due to the exceptional customer experiences they are uniquely positioned to create. (2015, Rae)

Coca-Cola, Apple, Nike and IBM are all listed on the Design Value Index. These companies have taken on design methods such as design thinking, design strategy, customer journey mapping, prototyping, co-design and the visualisation of data to better understand their customers and streamline their internal and also external business operations. These methods are all common to service designers who incorporate them to develop projects from a holistic, grass roots approach to design issues. Internationally, graphic designers are adopting these practices to expand their roles and merge with big business. Graphic designers, for example, are not just creating ‘good looking’ products at the end of the project process anymore. They are instead demonstrating an extension of their skills throughout the duration of projects; visualisation of project data is just one example of this. Graphic designers can use visual methods such as simple drawings to map out project data and clarify project problems long before end products have been decided upon. The global conversation about design and its growth in value has been ongoing for at least thirty years with companies like Apple Inc. seeing the merits of utilising design to expand its business operations during the 1980’s. A further escalation, however, in the prominence of design and its powerful uses has occurred over the past decade and the successes of this design evolution are usually demonstrated via large corporate examples.

Graphic designers work among all sectors of society. This is because graphic design is needed in varying capacities. We see the common, well-known products of graphic design everyday in iconic globally recognised graphic symbols like the McDonalds brand but we also see it as standardised basic communications in the menu of our local family restaurant. Documentation of design’s expansion is often delivered in terms of climbing up the ranks of big business but other fields are sharing how they are expanding roles for designers within large but also small project frameworks. Jeneanne Rae (2014), CEO of Motiv Strategies, an innovation strategy firm and author for the Design Management Institute, puts forth that for UX Design, the demand and expanse of design skills is not limited to large scale operations:

Companies across the business landscape, from start-ups to consulting firms to large corporations, all find themselves with digital opportunities for design - even those that historically have not competed in the digital realm. (Rae, 2015)
This statement depicts that designers in the User Experience industry have project opportunities for all sized firms due to the rapid expansion of digital uses. This industry focuses heavily on ‘user experiences’, the people who use their products, and they incorporate designers across all stages of project development to assist with product innovations so ensure they are customer focused. My research looks to explore the potential gap in the global dialogue about the shift in graphic design practice. I am looking specifically at graphic designers in smaller practices to explore the impacts of adopting new methods, such as those of service design, to expand their roles among small business projects.

Conclusion

The outcomes of my study are yet to be evaluated. However, further discussion about broader applications for smaller design scopes seems long overdue. There is opportunity to investigate the impacts of graphic design practice from many perspectives and not just through a large corporate lens. Research into varied design capacities could be considered a grass roots analysis of design process, instead of the seemingly top down approach to design review that appears to be most common amongst current design literature. Further studies into diverse design applications across broader industry types could reveal possible ways to generate a more extensive shift towards holistic driven practice for all areas of design. For future research in my PhD, I am incorporating the study of two studios to establish an overview of current graphic design methods being used among local industry projects and whether creative practices alter substantially after the introduction of service design processes. If local design practices do change, I will investigate whether this broadens graphic design roles among small commercial projects, and then explore the significance of these expanded positions. The findings from this study will be made available to the graphic design and small business communities of Perth and beyond.

Erica Ormsby

Erica Ormsby is a course coordinator and lecturer for graphic design at Murdoch University and a lecturer at Edith Cowan University for over 12 years. Erica has worked as a freelance Graphic Designer in Perth, Western Australia for over 15 years and worked among the print industry for over 20 years. Current projects include a doctorate in Philosophy. This study is an examination of graphic design practices in Perth, WA to determine the significance and value of design in broader contexts. The research looks to introduce holistic community focussed methods such as those of service design to graphic designers in Perth in an effort to expand their roles and relevance among small business projects. Others areas of research include critical design practice and theory, graphic design theory, service design and design thinking. Other practical roles have included art director, exhibition curator, project manager and small business owner. Erica holds a BA in Graphic Design and Multimedia from Curtin University of Technology and Honours First Class from Edith Cowan University.
Preserving Public Health: A Literature Review
Bryan D. Orthel, Ph.D., Manhattan, Kansas (orthel@k-state.edu)

Abstract
We recognize our past—history and heritage—as crucial to who we are (Grenville, 2007; Lowenthal, 2008; Nietzsche, 1874/1980). Significant regulatory and popular effort is expended in protecting places, buildings, and behaviors that link us to this past. International governance organizations recognize free association with history as a fundamental human right (e.g., Blake, 2011). Tangible representations of the past (e.g., objects, buildings, landscapes) are preserved as reminders of this past. Given the broad agreement that connections to the past are important parts of human existence, what are the connections between individuals’ security in knowledge of their own history and measures of public health?

The literature connecting preservation and public health is neither direct nor voluminous. A search for literature revealed a gap in knowledge about ways that preservation and public health relate. While some literature demonstrates possible connections between the two fields, no identified articles argue for the connection. Two examples from the preservation literature (Appler, 2015; Kearney & Bradley, 2015) explain situations where preservation issues have affected public health concerns, but do not acknowledge public health as part of their discussion. This exploratory essay briefly outlines core principles of public health and a review of literature from the public health and preservation and heritage fields that aligns with these principles. The essay concludes targeted research into the relationship preservation-public health is needed. 

Keywords: Preservation, public health, history, heritage, well-being

Almost fifteen years ago, Dannenberg et al. (2003) challenged researchers to explore the diverse and interconnected ways that design of the built environment affected human health.

The design choices we make in our homes, schools, workplaces, communities, and transportation systems can be major effects on health, which is defined by the World Health Organization as “a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity.” A healthy community protects and improves the quality of life for its citizens, promotes healthy behaviors and minimizes hazards for its residents, and preserves the natural environment” (Dannenberg et al., 2003, 1500).

Some research towards this goal has been completed, but the work is largely disciplinary (Dannenberg et al., 2003). Interdisciplinary opportunities to improve public health should not be ignored. This paper reviews literature for evidence of ways the historic preservation and heritage (hereafter preservation) and public health may relate. While preservation has been recognized as one of many approaches that may interrelate with public health (Budd, Lovich, Pierce, & Chamberlain, 2008), there is no direct literature evidence that this relationship has been explored specifically. Indirect evidence suggests tangible and intangible aspects of preservation may influence public health.
Preservation, heritage, and design

Historic preservation involves the repair, re-creation, stabilization, or protection of physical (tangible) historic artifacts at scales from objects to buildings to landscapes. Justifications for preservation of buildings, history, and heritage are often based in pragmatic concerns of economics and business (Koziol, 2008). While preservation often occurs privately, United States federal regulation outlines mandatory and recommended preservation practices that define the preservation profession in this country. Any project receiving federal monies must be reviewed to ensure historic resources are protected (e.g., Section 106 or 4(f)). Individuals and groups may also nominate historic resources for listing in the National Register of Historic Places. Neither of these actions provides guaranteed protection for the resources. In most cases, the resources are documented or recognized, but physical preservation choices are left to owners and local authorities. Preservation, then, serves to record, gather, and disseminate knowledge about the past.

Heritage covers a wider and more nebulous understanding of humanity. Heritage involves the relationship between tangible entities and intangible characteristics of human living that may result from common practice, tradition, cultural belief, or other understandings. Heritage ranges from storytelling (e.g., sharing the past with children) to cultural performances and daily activities (e.g., dance, cooking, dress, and traditions). While intangible heritage is recognized by international organizations, the concept remains less known in the United States and is not part of most preservation policies.

Design is linked to preservation and heritage. While there are obvious and long-standing connections between traditional design disciplines (e.g., architecture) and the protection of buildings and other design products, the strongest connection exists through design thinking practices. Allison and Allison (2008), Orthel (2014), and Orthel and Anderson (in press) discuss preservation and heritage as design problems. Design, preservation, and heritage problems are often social and inherently complex in ways that fit Rittel and Webber’s (1973) wicked problem theory (see also, Coyne, 2005). These problems are ill-defined, cannot be solved without changing the character of the problem, and no longer focused on simple meanings or physical objects. Similarly, Buchanan’s (1992, 1999) four orders of design (signs, things, actions, and thoughts) organize to the problems that design, preservation, and heritage address. Preservation has evolved from problems based on the first and second order of design to the more complex third and fourth orders. Design’s relationship with preservation and heritage is now about how to support people in their understanding and choices as about the past and their identities (Orthel & Anderson, in press). As a result, preservation must be addressed through the frame of design-based problem solving.

Evidence-based design is crucial to building a better world. Ulrich’s (1984) pioneering study on pain medication and views remains the touchpoint for ways designers can influence the human experience in ways they had not considered. Work continues to demonstrate multiple design actions and characteristics of the built environment that may influence health (Loukaitou-Sideris & Fink, 2009; Sallis & Glanz, 2009; Sallis et al., 2009; Malenbaum, Keefe, Williams, Ulrich, & Somers, 2008; Forsyth, Oakes, Schmitz, & Hearst, 2007; Frank, Engelke, & Schmid, 2003). Research and exploration improve the evidence designers use to solve problems.
Public health
In a traditional model, public health focuses on systems influencing broad societal health concerns (i.e., hosts, environments, agents, vectors). Public health research directly linked to the built environment investigates issues such as physical activity levels, injury prevention, air quality, public policies, and cross-cutting issues (e.g., politics, economics, crime, environmental justice and social equity, disability access, mental health) (Dannenberg, 2003). Connections between the built environment and public health have not always been recognized (Nash, 2006; Sloane, 2006).

Frumkin (2005) notes how mid-nineteenth century concerns about environmental health expanded into the current framework of public health. Specifically, he identifies two shifts incorporating the built environment into the public health paradigm. First, public health is concerned about environmental justice (e.g., housing or environmental hazards and effects on all people). Second, technology has changed how we analyze patterns of health and how we design buildings to support people. As a result, for example, we recognize indoor air quality is affected by building placement and envelope design. We see how transportation systems limit some peoples’ access to employment, health services, and society. Significantly, however, the public health literature often cannot match causation between the built environment and improved public health characteristics. For example, Ramirez et al. (2006) noted:

Evidence from transportation and urban planning studies suggests that persons living in neighborhoods with greater population densities, land-use mix, street connectivity, and walking and biking infrastructure (e.g., sidewalks and bike paths) tend to walk and cycle more frequently. …Although mounting evidence points to the potent impact of policies, physical environments, and social environments on physical activity, relatively little research exists on the precise nature, importance, and measurement of these variables (516).

Instead, the correlation of conditions provides evidence for advocating for altered policies and behaviors (e.g., Ramirez, et al., 2006; Saarloos, Kim, & Timmermans, 2009; Macintyre, Ellaway, & Cummins, 2002).

Connections
The important precedent question for exploring the connection between public health and preservation requires a hint that a relationship could exist. Preliminary thinking about the connection is based on two lines of possible inquiry: the influence of physical environment on health and behavior and the psychological influence of heritage and environment on health and behavior. Both lines are grounded in literature.

The influence of physical environment on health and behavior is established by common assertion and academic literature. The legal basis for most preservation regulation in the United States relies on an assertion that historic buildings and neighborhoods are desirable for the public good. Further, desirable attributes of built environment issues often identified by public health advocates can be aligned to characteristics of traditional neighborhoods and buildings.
The philosophical premise of preservation is based on the idea that historic environments are important for humanity’s well-being. Much preservation literature simply asserts the importance of people knowing their past. Recent developments have translated heritage into a basic human right (Bennoune, 2016; Blake, 2011; Hodder, 2010). More directly, Grenville (2007) argues the psychological well-being of individuals requires an awareness of how the individual fits into a past. As a result, she states that preservation and heritage engender “a sense of confidence and ontological security which allows an individual to escape the debilitating consequences of existential fears” about life in an unfamiliar, “transient and untrustworthy” modern world (Grenville, 2007, 449, 251). An individual’s understanding of their relationship in the historical world is identified as historical consciousness (e.g., Lowenthal, 2008; Nietzsche, 1874/1980). History is no longer a deductive exercise; history is an abductive consideration of cause, effect, importance, and relevance through the viewpoint of individuals. History must be “understood as a mental structure or competence that underlies our dealing with collectively important aspects of past, present, and future” articulated through individuals’ narratives (Kölbl & Konrad, 2015, 20). These values are often articulated in our physical environments (e.g., Williams and Patterson, 2008; CABE, 2005).

If a valid and viable connection exists between public health and preservation, then rigorous and intellectually solid research will be needed to support design-based problem solving and practices. Review of existing literature connecting the two ideas provides a starting point.

**Literature search**

Exploration of the literature linking public health issues and historic preservation began with database searches. The searches produced in surprisingly few results: Academic Search Premier (n=1), Avery Index of Architectural Periodicals (n=1), Scopus (n=5), ProQuest (n=174), Web of Science (n=1), and WorldCat (n=33) (total=214). Duplicate results and non-scholarly entries (i.e., media reports) were removed from the sample. See Table 1 for quantitative reporting of the search results. These articles were reviewed for content linking public health and preservation.

Additional articles previously known to the author were included in the review. These previously known articles had prompted the original question about the link between public health and preservation or provided context to that question. Other articles provided a working definition of public health.

Police powers and government interests
The largest set of articles (n=25) connecting public health and preservation emerges from legal and planning discourse about property rights. The seminal U.S. Supreme Court case of Berman v. Parker (1954) affirmed the use of eminent domain to take private property for a public purpose. In the case, non-blighted, privately-owned land was declared blighted to enable an Urban Renewal project that demolished buildings across multiple properties. The Court decision established that the police powers of the Constitution support such actions and outlined broad ways that governments may act to enhance the health, safety, and welfare of its citizens.

This literature does not directly support public health and preservation, but explains the shared technical means that can support both concerns (e.g., land use and planning and zoning regulations). For example, Caros (2016) provides an overview of police power case law that linked the Berman v. Parker case with earlier decisions (e.g., Euclid v. Ambler, 1926) and later decisions (e.g., Penn Central v. New York, 1978). Another line of scholarship in this area focuses on ethical issues deriving from this and other laws that preference public good over individual rights (Ostrow, 2008; Salkin & Lavine, 2008).

The legal line of scholarship is most important for recognizing broadly defined well-being as legitimate governmental policy. A long line of case law and regulatory language asserts public goals beyond protecting basic human safety or constitutional rights. The Berman v Parker case, for example, directly states that governments can consider creating beauty a legitimate government aim. The Court accepted that public good comes from intangible characteristics. Contemporary preservation policy and actions are heavily linked with design standards and zoning regulations enabled by these legal principles. Beyond case law, this literature also explores public and governmental attitudes towards protecting features of the built and natural world. Tyrrell (2012), for example, documents the national park ethos creating “national and state parks throughout the country that would combine the appreciation of beauty with the provision of recreational spaces that would alleviate the social and environmental conditions of American cities” (19). The legal sub-set of the literature provides regulatory and conceptual cover for how policies and behaviors are part of American society.

Planning and health
The second literature set (n=24) addresses characteristics of environments that support public health goals. None of this scholarship directly links preservation and public health, but suggest a potential link in associations that are made.

Much of the research in these articles relies on the principles of smart growth planning (e.g., Mobarak, 2016; Handy, Sallis, Weber, Maibach, & Hollander, 2008; English, M.R., 1999). Smart growth policies emerged in the mid-1990s in response to concerns about urban sprawl (e.g., density, pedestrian and vehicular access, access to public amenities). Smart growth principles encourage new development mirroring the traditional forms of historic neighborhoods
(including density and mixed uses), planning for the connection between places, and recognition of the human experience in the built environment. Smart growth has been critiqued as exclusionary and elitist.

Part of this literature addresses the location of school buildings, urban development patterns, and childhood obesity rates. The literature notes competing goals for creating adequate physical play space and school locations in suburban areas unsupportive of pedestrian access (Schlossberg et al., 2006; McDonald, 2008 & 2010; Heelan et al., 2008). Lopez (2004) more generally links suburban sprawl with increased obesity rates. This literature does not specifically endorse historic or traditional urban forms as the solution, but does describe characteristics which are shared by older and traditional areas.

Maguire, Foote, and Vespe (1997) outline a history of aesthetic regulation in the twentieth-century United States and link aesthetics with corresponding human behavior and health. Their argument lacks scientific data, but highlights the common perception that the aesthetics of an environment shape human behavior (positively or negatively).

In total, this literature does not directly connect preservation and public health, but aspects of both fields are present in the discussions.

Social justice
The third literature set (n=5) discusses social justice issues that overlap between public health and preservation. Two of the articles (Peña, 2008; Allen, 2007) draw attention to implications that followed the destruction of neighborhoods and social structures in post-Katrina New Orleans. Baumann, Hurley, Altizer, and Love (2011) explain the inclusion of social justice and public health issues in the interpretation of the Scott Joplin House State Historic Site. Recent reinterpretation of the site has incorporated contemporary “violence, racism, prostitution, disease, and sanitation” issues as part of the history of the site and Joplin’s life (38). These articles show public health and history as interconnected issues.

Two of these articles present public health and preservation in less direct associations. Brown (2005) argues the protection of intangible cultural property must safeguard the rights and access of minority groups to their past. He shapes the issue as concern for individual (or group) autonomy, but contrasts the value of heritage with other issues that merit attention, such as public health and education. He does not seem to see a connection between these issues. Fatorić and Seekamp (2017) note that public health issues could be interrelated with preservation and climate change, but offer no specifics. While these five articles suggest possible connections between public health and preservation through social justice issues, none of them yet show scholarly exploration of the issue.

Other literature
Literature identified outside the database searches suggests a more direct, if still disciplinary, potential relationship between preservation and public health. This literature emphasizes aspects of traditional neighborhoods or buildings that may support public health. For example, Williams and Patterson (2008) highlight the role sense of place and belonging play in supporting leisure, health, and well-being. Several articles link access to green spaces to the promotion of mental
health, reduced stress levels, increased social capital, and increased physical activity (Burls, 2007; Mass, van Dillen, Verheij, & Grootenwegge, 2008). Another subset of the literature explores the redevelopment of brownfields through smart growth policies. They argue brownfield redevelopment repairs the urban form and improves public health by removing hazards and reconnecting people (Greenberg, Lowrie, Mayer, Miller, & Solitaire, 2001; Wedding & Crawford-Brown, 2007). Other articles provide general analysis of public health concerns (e.g., obesity) and neighborhood characteristics (Day, Boarnet, Alfonzo, & Forsyth, 2006; Harrington & Elliott, 2008). While none of this literature begins from a preservation-specific vantage point, the articles highlight concerns about human well-being that may align with long-standing building patterns in towns and cities.

Two notable articles are presented by preservation-based authors. Kearney and Bradley (2015) explain that alterations to heritage knowledge affect a community’s foodways, physical activities, and social interactions. Unfortunately, the authors do not connect these observations with public health. Appler (2015) highlights potential benefits associated with locating housing in urban historic districts as opposed to non-historic areas (e.g., location to public services, improved quality of life). His analysis of the physical distances directly ties characteristics of historic areas (e.g., density, walkability, established public entities) to the public health concerns associated with connections to transit, schools, and parks. While both articles connect preservation and public health ideas, neither discuss a link between the two fields.

Another side to this relationship emerges in literature discussing competing outcomes between public health and preservation. Grüning, Strünck, and Gilmore (2008) argue, in part, that contemporary German reactions against past, fascist approaches to public health research has hindered the development of effective twenty-first-century policies curbing tobacco use. The potential negative influence of preservation and public health on each other’s goals must be part of any future interdisciplinary research.

Conclusions
Review of current literature potentially relating public health and preservation highlights the opportunity for the two fields to be more closely connected and the need for concerted exploration to define how the fields relate to each other. The literature identified through database searches demonstrated a weak connection, but literature identified through broader reading shows a strong potential for ways that preservation and public health can support each other’s goals.

This gap in the literature may be the result of disciplinary focus on the core aspects of each field. Both public health and preservation professionals focus on advancing their respective purposes first. This gap does not need to continue. Interdisciplinary research and applications would benefit the two fields. The challenges of interdisciplinary work and design-based problem solving will push both fields.

Discussion
The literature search identified three themes of potential scholarship that were expected: police powers (and legal issues), planning and health, and social justice issues. The lack of academic work directly connecting preservation and public health was unexpected. While some literature
demonstrates a potential connection between the two fields, this connection appears to have gone unnoticed. There is a clear opportunity for targeted, interdisciplinary, and methodologically sound research exploring how preservation and public health can support symbiotic objectives.

It also is notable that almost none the identified literature emerged from a preservation-based vantage point. Allied disciplines (e.g., planning, public health, anthropology, environmental history) are exploring and expanding this knowledge, but the preservation and heritage-based scholars are currently focused on other topics. This outcome is unsurprising, but still disappointing. While preservation scholars are active and productive within their parameters, there is too little effort to connect to a broader and interdisciplinary world. Recent shifts to include values-based policies and critical heritage (and increasing awareness of racially, ethnically, and socially diverse vantage points) are changing preservation’s actions and interests, but the field maintains a central concern for tangible things (e.g., buildings or objects). The field rarely conceptualizes its work with other ideas—and when it does the primary purpose is to advance more preservation rather than to integrate preservation in a larger social context (e.g., the Main Street Program and economic development or the Preservation Green Lab and sustainability). Research exploring the interrelationships identified in this essay would be a good starting point to connect the preservation literature to contemporary society.

To develop literature linking public health and preservation, scholars must be prepared to use design-based problem solving. The problems in public health are complex social and ecological issues. Preservation and heritage are similarly dealing with unique, individual-bound understanding of meaning and the past. While scientific study of these conditions will provide some answers (e.g., Ulrich, 1986), other aspects of the problems will only come from understanding people in the context of their own lives (e.g., Stevens & Hildebrandt, 2009). Regardless of the approach, the connection between how people understand their past and their health holds promise for future work.

Acknowledgements
My initial introduction to public health literature came through a seminar course taught by John Abell (Washington State University). The maturation of ideas from that course to now has been slow, but would not have occurred without his passionate presentation of the public health viewpoint. I am grateful for the intellectual challenge.

Bryan D. Orthel

Bryan D. Orthel is an assistant professor at Kansas State University. He completed a Ph.D. in interdisciplinary design at Washington State University, a Master of Historic Preservation at the University of Kentucky, and a professional bachelor of architecture at the University of Oregon. His scholarship focuses on perceptions of history and preservation, as well as the scholarship of teaching and learning for design.
Enhancing Creative Confidence through Sketchnoting, 
A Foundational Research Exploration

Verena Paepcke-Hjeltness Department of Industrial Design Iowa State University Ames, Iowa, USA verena@iastate.edu

Aziza Cyamani 
Department of Industrial Design Iowa State University Ames, Iowa, USA aziza@iastate.edu

Abstract
Sketchnoting, if seen as a methodology, exhibits potential for systematic and methodical research. It provides a framework to communicate visually through simple shapes, breaking complex forms down into combinations of dots, lines, squares, triangles, and circles. Situated at the lower end of the visualization spectrum, which ranges from napkin style sketching to photo-realistic rendering, it has low barriers to putting pen on paper. In the context of an industrial design graduate course originally introduced as a gateway to traditional visualization in design, sketchnoting exhibited greater potential to not only lower the threshold of sketching, but in addition, to foster creative, and in some cases, even boost design confidence. These anecdotal observations revealed several overarching opportunities for a larger, cross-disciplinary research, which would begin with exploring the ability to foster creative confidence through lowering the inhibition threshold to drawing for designers and non-designers alike. Proceeding to explore the potential of sketchnoting (due to its dual coding nature) becoming an entry point to employing all modes of thought processing, deductive, inductive and abductive logic as they pertain to divergent and convergent thinking. Ideally setting up this framework to be investigated as a means to improve student engagement and general learning behaviors. The long-term and underlying goal is to change how people see and solve problems and to diversify stakeholders involved in the development processes. This paper discusses the underlying concept as well as the originally observations, closing with the above-mentioned series of research opportunities.

Keywords: Creative Confidence. Sketchnoting. Idea Visualisation. Design Thinking.
The dictionary defines learning as acquiring wisdom through different methods. Generally, those methods include being taught, through experience or studying. In the case of design courses, students are expected to learn through a mixture of input and output, acquiring different skillsets as a means of facilitating expression with the primary goal of applying creativity to design. Design in practice and design thinking specifically, conjoins the two elements of wisdom: “thinking and doing” as discussed in “The Design Way, Intentional Change in an Unpredictable World” (Nelson & Stolterman 2012). This iterative process manifests itself at the core of the design process where synthesising information into meaningful knowledge is done through the diverging and convergent thinking processes. Here, designers are able to think broadly, and in narrow spectrums, expanding their outlook and narrowing down their focus on the most useful knowledge.

Figure 1: Visual adaptation of work by Nelson & Stolterman, Mike Rohde, and Betty Edwards

To equally apply (design) thinking and doing during the design process, designers use techniques of various forms to uncover and communicate problems, identify patterns, tell stories, develop ideas, detail concepts, implement and communicate solutions (Baskinger & Bardel, 2013). At the top of this hierarchy lies “visualization” as a major way of
facilitating synthesis and communication. This is usually done in the form of sketching. Sketching is used as a form of expression, exploration and communication of ideas between designers, and during collaboration with other people from outside of their fields. It is considered as the most efficient and straightforward way of communication that would otherwise take longer to explain using other means. It is, therefore, often regarded as a crucial skill in this profession.

Tom and David Kelley (2013) point out in their book “Creative Confidence, Unleashing the Creative Potential Within Us”, that a common misconception lies in believing in an individual’s innate ability of being able to draw or not. This leads to people thinking that because they cannot draw now, they will never be able to. The resulting frustration can cause low esteem and insecurity, lowering the individual’s interest in sketching and consequently affecting their creative confidence. Tom and David Kelley (ibid) discussed this as a result of the misunderstanding in the attributed relationship between sketching and creativity; they state that a lot of people perceive drawing as a litmus test for creativity.

Therefore, an opportunity space exists at the lower end of the visualisation spectrum as an alternative approach to learning sketching. This paper discusses an ad-hoc research approach based on anecdotal observations that were made through an introductory class of visualization in Industrial design. The hypothesis focuses on using low fidelity visualization methods, such as Sketchnoting as a low barrier, low expectation and low pressure method to teach new designers and non-designers alike the fundamental skill of visualization.

**Literature Review \ Sketchnoting \ Visual Sensemaking**

The term Sketchnoting, which was originally coined by Mike Rohde derived from his desire to take more engaging and meaningful notes. It is a form of visual note taking that engages the whole mind. Rohde (2013) defines Sketchnotes as “visual maps combining written words and images while providing structure through variations of frames, dividers, bullets, icons, and connectors such as arrows and lines.” (Figure 2)
Visual listening notes are taken in real time, just like notes solely focusing on the written word. However, these visual notes can turn traditional notes into meaningful synthesized interpretations of discussions, lectures, debates, and the like (ibid). They can contain mainly words, frames, containers, and dividers and do not necessarily require actual imagery such as icon-like drawings. However, many Sketchnoters create their individual visual library of shapes, forms, icons, images, and arrows to effortlessly draw from. The continued practice of drawing the same object over and over gives the Sketchnoter confidence and command thus making it easy for them to repeat it on demand (figure 3). Every Sketchnoter has his or her own characteristic handwriting that can be seen on sites such as the sketchnotearmy.com. Due to the fast nature of life note-taking Sketchnotes can be disorderly and can contain spelling or content mistakes. Making, accepting, and turning mistakes around is an important component of this process.
In recent years Sketchnoting has developed into a large community of practice, with presence at different academic institutions and online platforms where Sketchnoters freely share their notes. The notion of combining written words and images has been practicing by graphic recorders for many years, many of which are members of the International Forum of Visual Practitioners (IFVP), a community of graphic facilitators who seek to “help people see what they mean” (IFVP, 2015). Graphic recorders work on large-scale paper or whiteboards for everybody to see and reflect upon. Sketchnoters mainly work in sketchbooks, on small paper, or tablets. However, both Sketchnoters and graphic recorders listen, synthesize and interpret discussions ad-hoc. David Sibbet, founder of The Grove Consultants International and a pioneer in the field of visual consulting elaborates in “Visual Meetings, How Graphics, Sticky Notes, and Idea Mapping Can Transform Group” on how to use and develop visualization techniques to capture and facilitate meetings (Sibbet, 2010). He argues that by focusing on visual outputs people
have not just better ideas, but they also make better decisions. In addition they tend to be more prone to follow-through.

Omitting unnecessary details allows to focus on speed while capturing ones own comprehension of thoughts and concepts. This way of quickly visualizing and abstracting complexity supports pattern finding and communication alike. The low fidelity nature of sketchnoting supports fast learning and promotes a low inhibition threshold of putting pen to paper. Resulting in a sense of achievement and openness to practice.

There are several advantages that can be derived from the low fidelity visualization of sketchnoting:

- Quickly synthesizing what was heard and seen
- Making connections and discovering patterns
- Sharing information with others visually
- Improving memorizing information
- Promoting active note taking
- Embracing to make mistakes

**Research Methods**

The lead author introduced traditional Sketchnoting methods on several occasions, one of which is being discussed here to make a case for a larger research study and implementation strategy for Sketchnoting. Due to the ad-hoc nature of these observations research questions were not the initial focal point. However, at this stage the observations were mainly anecdotal based on several large-scale workshops with industrial design students (sophomores to seniors) as well as an industrial design graduate course. the latter being discussed here. Students had varying skill levels regarding their visualization ability and therefore had different entry points. The focus of this exploration was on student work improvements over the course of a semester, their overall learning behaviours, and increase in quality and depth of work. Research methods were comprised of comparing and contrasting deliverables of
course assignments as well as observations of in-class performances. This included comparing the development of quality in depth of work, craft, and innovative outcomes.

**Discussion of Graduate Coursework**

During the beginning of a course on visualization, industrial design and architecture graduate students were exposed to Sketchnoting via hands-on lectures, where they practiced visual elements simultaneously while being introduced to them. As a starting point students were tasked to develop a visual library that pertained to their personal environment. In this exercise, they had to choose at least 30 visual elements (figure 4) and each had to be drawn at least 50 times to develop confidence in putting pen on paper and to develop fluid muscle-brain memory.

![Figure 4: Visual Sketchnote library](image_url)

These elements would become the backbone of a narrative story pertaining to their educational path, which they had to sketch out in the end as seen in figure 5. During both of these exercises, it became apparent that some students immediately embraced this low fidelity type of visualizing and excelled at it. Students who were not as confident and proficient in sketching initially avoided developing a visual library and did not seem to want to practice low fidelity visualization at all.
However, as these students continuously got accustomed to developing elements in their visual library, and started applying them to their Sketchnoting stories, a significant shift in confidence and interest was observable. Consequently, some students went further and applied Sketchnoting to a variety of process steps in other classes such as studio courses, where they started presenting their ideas in this format. They seemed to have also grown more confident in trusting their own design decisions better. The latter was an unexpected outcome.

Based on these anecdotal observations as well as work derived from Adaptive Path (a service design studio) and the HCI community (Petersen, 2012; Marquardt, N., Greenberg, S. 2012) the following preliminary hypothesis was formed: Sketchnoting could become a relevant tool in fostering synthesis for problem finding and solution development as well as helping to bridge the gap between divergent and convergent thinking. It could also be used as a problem framing and idea generation method.

The following are some notable opportunities that could be drawn from employing this type of visual sense making.

- Lowering the inhibition threshold toward drawing
- Fostering idea generation through increased creativity confidence
- Bridging the gap between divergent and convergent thinking
- Improving in-class engagement and learning behaviours
Conclusions // Avenue Towards Greater Research

Through these anecdotal observations the team discovered the following aspects as worthwhile research avenues to be explored systematically and applying rigorous methodologies.

Fostering Sketch Confidence

Sketchnoting, seems to lower the inhibition threshold of putting pen on paper. It provides an almost immediate feeling of success of being able to communicate on paper. For design students in particular, but also for non-designers this could help to break the vicious cycle of avoiding practicing to sketch due to the positive feedback-loop.

Developing Creative Confidence

According to Kelley and Kelley (2013) not being able to sketch directly affects the perception of one owns creative confidence. Acquiring visualization skills to communicate ideas freely and easily without fear of imperfection and mistakes could be the first step to trusting ones own creative ability. Once sketch confidence would be established, the creative flow could happen seamlessly, encouraging collaboration and triggering unexpected and possibly disruptive ideas.

Growing Design Confidence

By promoting all modes of thought processing through it’s dual coding approach, Sketchnoting could support to not only put more and diverse ideas on paper quicker, it could also support visual synthesis of complex information. Both could greatly aid in the design process and influence overall design confidence.

Positively Affecting Learning Behaviours

Exploring Sketchnoting through the practice of lecture note-taking and visual analysis of reading materials it could have potentially significant influence on student class engagement and learning behaviours.
In conclusion, these anecdotal observations revealed opportunities to investigate the potential of Sketchnoting through larger scale research studies exploring low fidelity visual communication skills for design novices and non-designers alike. The research team is currently investigating and setting up opportunities to work with Electrical Engineering students, Industrial Design students, as well as with faculty, staff, and graduate students across the university.

Author Biography

Verena Paepcke-Hjeltness

Verena Paepcke-Hjeltness has worked both in Germany and the U.S. as an industrial designer with a focus on aviation and transportation design. She graduated from the University of Applied Sciences in Potsdam Germany with a degree in industrial and environmental design and earned her M.F.A. in industrial design at The Ohio State University. Currently, Paepcke-Hjeltness is an Assistant Professor of Industrial Design at Iowa State University and jury member of the IDSA International Design Excellence Awards (IDEA)®. She was previously appointed Assistant Professor and Associate Program Director at Drexel University. She taught for many years at the Savannah College of Art and Design were she founded and originally lead the M.A. and Undergraduate Minor in Design for Sustainability and later coordinated the eLearning Program in Design Management. Throughout the years she has taught several industry-sponsored courses with companies such as Gulfstream, Freescale, Newell Rubbermaid/Goody, and Dell, as well as community based design projects with the City of Tybee Island and the Rochester Library in Illinois.

Her research focuses on the diffusion of design thinking and doing practices in design and non-design oriented disciplines, with a focus on exploring low fidelity visualization techniques as a gateway to creative confidence and design-ability.

Aziza Cyamani

Aziza Cyamani is a third-year Master’s student in the Department of Industrial Design at Iowa State University. Her experiences span from working as a designer in Rwanda, where she earned her Bachelor’s degree in Media design at the Kigali Institute of Science and Technology, to pursuing a career in teaching design courses. She worked as a Teaching assistant in the department of Creative Design at the University of Rwanda for two years, founded a start-up company that provided graphic design services and worked as an Industrial design intern at Mass Design Group with a focus on furniture design. Her research interest is in understanding ways of incorporating sustainability in industrial design curriculums on which she is writing her Master’s thesis that focuses on developing countries. She currently works as a Teaching/Research Assistant in the department of Industrial design at Iowa State University.
Differences of Cast Shadows on Food Image Perception

Sakay R. Oscar E., University of Tsukuba, Tsukuba-Japan, s1621377@u.tsukuba.ac.jp

Yamanaka Toshimasa, University of Tsukuba, Tsukuba-Japan, tyam@geijutsu.tsukuba.ac.jp

Abstract

Light in photography is considered by most practitioners as one of the most important visual element since through it the human is able to recognize shapes, texture, color depth and even create diverse moods in the images. In food photography, light settings also imply the creation of several forms of shadows which become a secondary visual element. Thus, the effects of different types of shadows on food photos can generate different perceptions of the food creating either a positive or negative impression on human behavior.

This paper aims to explore the usage of cast shadow on food photography in order to open a new discussion in this topic. The main approach was to create and survey food images with several cast shadow composition; evaluate them and determine if the difference of cast shadows has an impact on how food images are perceived.

As a result, the experiment showed that different cast shadows affect not only the mood in which food is perceived but also the taste of the food. These findings can be useful to explain how cast shadows are also a key visual element in the decision making process or human behavior when choosing what to eat from a group of food images.

Keywords: Food Photography, Visual Elements, Cast Shadows, Perception, Human Behavior
Food images are widely used as a marketing tool when it comes to advertise a restaurant. For instance; attracting new customers (as external marketing), as well as for designing more appealing menus in order to persuade customers to choose a more profitable dish (as internal marketing). Usually the process of creating food images, involves three major participants: the chef, the photographer and in most cases a food stylist or food coordinator, whose role is to create balance in colour and context between the food and its surrounding.

**Literature review**

In photography there are several techniques applied to the creation of food images. Each technique has been developed in order to enhance visual characteristics of the food. Although food images can be classified according to its purpose; labels, menus, pamphlets, websites, etc., it is possible to identify several visual elements within their composition. Additionally, colour, lightning, background, decorations, shadows and camera angle are some if not all the visual elements that have to be considered when creating this type of images. For this reason, several scientific researches have been conducted in order to see how most of these visual elements have an influence on the taste of the food (Mizutani et al., 2010; Wada et al., 2010), the purpose of this research is to explore the influence of shadows on food image perception.

According to Da Vinci (2009), shadow can be defined as “the absence of light, merely the obstruction of the luminous rays by an opaque body. Shadow is the nature of darkness. Shadows always exists whenever there is presence of light and an object. Therefore, to speak about shadows is necessary to speak about light as well”.

Furthermore Mamassian (1998) said; “In order to understand the information content of shadows, it is important to recognize that shadows come in two types, depending on how they are formed on surface”. In figure 1 we can see the different elements that compose shadows.
In this way, shadows are important in human perception since they provide important visual cues such as relative positions of objects, information about the geometry of a receiver (background) and information about geometries that are out of the field of view (Hasenfratz et al., 2003).

**Research Method**

There are several types of food worldwide; each country has its own type of food, presentation, colour, textures, etc. Also there is a vast amount of descriptors for each type of food. This paper focuses on a preliminary shadow evaluation of two shadows schemes which will be denominated “soft shadows” and “hard shadows”. On a previous study made on this research, a shooting procedure was created in order to avoid certain visual elements such as colour, lightning, etc. to differ from each shadow scheme (Sakay O. et al., 2017).

In order to evaluate how does both shadows schemes have an impact on food perception, a survey was designed using 18 food descriptors and sensory related words (Fig. 2).
These words were chosen after running a small survey with several practitioners (experts on image creation) and people with no knowledge on food image creation. The criteria chosen to select the words was the frequency in which they were chosen by the participants. The objective of this preliminary shadow evaluation is to narrow down the food types as well as to see which food descriptors have an impact over these 2 shadows schemes. Separately a second survey was also designed to explore the level of awareness of the participants towards different visual elements such as lightning, colour, shadows, camera angle, background and decoration.

Participants
Graduate and undergraduate students were recruited from the University of Tsukuba (aged 20-30 years, M=24.5, SD= 2.72). All participants had a self-reported normal sense of sight.

Stimuli
A total of 60 images were created using the shooting procedure mentioned above; 30 of the images with the soft shadow scheme and its counterpart with the hard shadow scheme. All images were printed on photographic glossy paper (Epson Crispia) using an Epson PX-5002 K3 technology professional printer which was properly calibrated in order to get accurate images in terms of colour and brightness. In addition, the environment where the experiment took place was also properly set to avoid colour distortions due to the temperature of the light in which the image were going to be shown. The food chosen to create the images were classified in 2 groups: A) raw food such as fruits and vegetables, B) manmade food such as cakes. It was also considered to use other types of foods such as hot dishes, but limitations with the shooting environment did not allowed the creation of these images and therefore they were excluded from the research.
Surveys and evaluation scale

The first survey used was the visual elements evaluation (survey A), in this survey the participants had to evaluate how important they consider the following visual elements: Colour, Illumination, Background, Decoration, Shadows and Camera Angle. The second survey (Survey B) the participants have to evaluate the descriptors shown on Figure 2. In both surveys, an intensity scale from 0 to 6 was used, being 0 the lowest rate value and 6 the highest.

Survey procedure

At the beginning of the experiment, all the participants were told to recall any food image of their choice. After they recalled the food image, it was requested complete survey A. Immediately after completing the survey, food images were randomly shown and while gazing them, the participants proceeded to answer survey B. After completing survey B they had a small refreshing brake to proceed with the next image until all 60 images were evaluated (within-participant design). Figure 3 illustrates the procedure.

![Figure 3: Experimental procedure](image)

Results

Survey A was analysed using a mean rating value for each visual element. The results showed that colour was rated as the most important visual element with an average rating of 5.39 while shadows was rated as the least important visual element with an average rating of 3.11. This can tell us that the level of awareness of the shadows on food images is low. Furthermore this unawareness could lead us to believe that shadow evaluation is subconscious due to the unique properties of shadows. (Fig. 4)
Survey B was analysed by obtaining the difference of means between both shadows schemes on each of the words evaluated. Figure 5 shows the results of the analysis.

For both shadows schemes, the evaluation of vegetables and fruits were higher than cakes when comes to descriptors such as juiciness, freshness and healthiness. This could be explained since when we look at an image of an orange, we also recall our knowledge and experiences with oranges. For example, how much juice it might contain; the way we have learned how eating
oranges are good for our health and through the orange colour, lightning condition and
texture we are also able to assess its freshness (Wada et al., 2010. Also, Figure 5 shows that
cakes had higher difference of means on descriptors such as excitement, deliciousness,
safeness and coldness. Finally fruits showed higher difference of means on descriptors such
as sweetness and crispness.

So far the preceding paragraph remarked which descriptors have the biggest differences
on each food category, but this does not mean that the analysed data follows a pattern.
Therefore a paired T-test (p-value < 0.05) analysis was performed on all 18 descriptors and
the results showed that excitement, deliciousness, freshness and crispness had statistical
significance. With these results, cakes we chosen as food category for further shadow
research since it was the category that had the highest amount of descriptors with statistical
significance. Furthermore cakes have a unique property of not providing visual cues
regarding its actual flavour while fruits and vegetables does. Thus, abstraction is
considered necessary to really comprehend the role that shadows have on food image
perception.

**Conclusions**

Depending on the type of food, the perception of shadows is different. In other words if
we talk about raw food (vegetables and fruits), our subconscious is already programmed
to visualize these foods in the wild (on a tree, in a farm, on the ground, etc.). It is on
this type of locations where the lighting conditions, hence the shadows conditions
correspond to the hard shadow scheme. However, cakes cannot be seen in the wild since
they are manmade food and therefore its natural environment is the display window of a
bakery with artificial light. We know that cakes are a combination of different ingredients
but the output can take different shapes, colours and textures. Although we might
have had experience with a certain type of cake (chocolate cake), judging the cake by its
colour could be deceitful. Additionally if the cake does not possess any other type of visual
cue that could give away the flavour (fruits), the actual flavour will be uncertain until we
actually try it, making this type of food suitable for further experimentation.

Abstract
Doctors who specialize in cancer often need to communicate a great deal of critical information to their patients during times of intense emotional stress. Doctors working with patients with acute myeloid leukemia (AML) need to present all treatment options in a way that ensures patients make choices that are well-informed and consistent with their values and beliefs, often at their initial visit. Patients need to feel confident in their decision making, especially in cases where supportive care is a consideration (treatment intended to ease pain but not arrest the progress of the disease), or when the side-effects of treatment are substantial. We wanted to create a protocol grounded in the literature of doctor/patient communication, but applied principles and methods from Service Design to make the end result patient-centered and usable. The introduction of Service Design to the project fundamentally shifted its aims and scope. Additionally, the design process itself had a positive impact on the efficiency of the project team.

Keywords: Service Design, patient journey maps, doctor/patient communication, cancer

Acute myeloid leukemia (AML) is a cancer of the blood that most often affects people who are 70 or older. Dr. Larry Cripe has been treating patients with AML for 35 years and has ample experience in an aspect of treatment that is scarcely covered in medical education—how to inform patients of the diagnosis of serious illness. He initiated the project with the intent of creating a screen-based tool to communicate basic information about AML, and relevant
information for making decisions. It was important for the tool to be available to the patient after appointments, for reference, and that it help facilitate communication with family members.

Patients also needed to be made fully aware of the risks of the disease and its treatment. A problem inherent with full-disclosure of treatment relating to serious illness is that, while necessary, full-disclosure can be destabilizing. Patients reeling from a cancer diagnosis are frequently overwhelmed and shut down rather than hear more about their disease or its treatment options. An inability to listen during the appointment, or access the information later, causes patients to powerless when faced with making decisions. (Nissim) Our aim was to create a tool that helped patients feel fully informed and confident in their choices going forward. We wanted our tool to help patients feel sturdy.

**Literature Review**

From literature in health communication in cancer, we know the following:

1. Patients see little relevance in aspects of decision making that are valued by doctors (Koehler)
2. Patients feel treatment for their cancer is the only choice (supportive care is not considered a matter of choice) (Nissim)
3. Patients tend to trust in the expertise of their doctor (Nissim)
4. Recommendations are not fully evaluated by patients due to a sense of urgency (Leppin)
5. Patients demonstrate poor recall and report feelings of being overwhelmed. (Nissim)

In regard to the use of patient journey maps, specifically in cancer treatment: We know that in 2015-16, the Curtis and Elizabeth Anderson Cancer Institute at Memorial Health University Medical Center in Savannah, Georgia, worked with a design student at the Savannah College of Art and Design to produce a pair of patient journey maps, in response to similar findings. (Innovating in Cancer Care, 2016) However, the key outcome of the research for the design was the design itself, the project (as of yet) has generated no publicly available academic outcomes. As design begins to proliferate in medical schools through medical education and research, we predict more scholarship will be done in this area.

**Research Methods**

Our work took the form of a four-part process design process. We designed a patient journey map (Figure 1) that covered a 90-day patient experience from pre-diagnosis to out-patient follow-up care. The map was constructed using data from audio recordings, observations from doctor appointments, and discussions with doctors.
The patient journey map caused the team to revise its assumptions about the aims of the project itself. In response, we proposed each of us individually engage in an exercise to identify potential problem spaces, essentially going “back to the drawing board.” We asked everyone to write a series of “How Might We...?” statements and shared them with each other to re-align our efforts. The responses were illuminating as they revealed the underlying interests and assumptions of each team member. We finally decided to focus on the initial patient meeting with the twin goals of comprehension and expectation setting. We designed artifacts (worksheets) based on Dr. Cripe’s reporting of his own practices. (Fig. 2) After they had been vetted by the team, the worksheets were used in role-play situations, then re-designed (iteration). Our next step (as of October 2017) is user-testing with former patients and their families.
Discussion

Design has much to offer doctor/patient communication, however we have found that designers are very rarely engaged in the creation of patient communication tools with teams of doctors. While we continue to refine our work in preparation for user testing/piloting, we feel that our work has yielded the following lessons:

1. Seeing the patient’s experience through a patient journey map can be invaluable for doctors, who may have only incidental insight into how a patient thinks or feels.
2. Re-constructing the patient journey from various sources (interviews, recordings of doctor visits, journal articles) and mapping them onto a patient journey map can fundamentally shift project scope and direction. Before the map, clinicians on our team focused on providing a comprehensive description of AML and its treatment options. After viewing the patient experience through the map, it was clear that patients needed to be guided through the information on an ‘as-needed’ basis, dependent on where they were in treatment and sensitive to their emotional journey.
3. While doctors are aware that too much information is overwhelming to patients, a patient’s ability to give consent for treatment rests on having complete information about procedures, potential benefits, and potential risks. Striking a balance between comprehensiveness and comprehension is an on-going issue.

Conclusion

Our study is ongoing. User-testing of the worksheets is our next project milestone, and as of this writing, October 2017, we are close to initiating them with former patients and their families.

Regarding the implications of our project for design: The tools of the service design method, in particular, were viewed by our study team as helpful not only for establishing relevance with patients (“does our solution make a difference for patients?”) but also for “jump-starting” study progress (“we’re stuck, what now?”) and maintaining it. Referring to designed artifacts—maps and worksheets—helped the team build cohesion, and their iterative development over time built
a series of commonly held, visual and physical reference points. The inclusion of a designer in this process meant that a non-medical specialist was always present to represent the experience and “story” of the patient. By introducing Service Design to the development of a communication tool, we aim to help AML patients become well-informed and sturdy.

Helen Sanematsu
Professor Sanematsu’s research brings people-centered design approaches to patient experiences and community health. She serves as Associate Director for Communication for Community Health Partnerships (CHeP)—the community-centered initiative of the Indiana Clinical and Translational Sciences Institute (IndianaCTSI)—Sanematsu oversees a staff of four designers on projects that help ensure relevance in university-community partnerships. She is the founding designer/design researcher for the Patient Engagement Core, which assists health studies at Indiana University, Purdue University, and the University of Notre Dame with people-centered approaches that integrate patient perspectives into research. Her work extends the reach of design for communication and design research into health services through the application and exploration of best practices and new methods. She has been a co-investigator or project partner on a number of interdisciplinary studies with the IU School of Medicine, the Fairbanks School of Public Health (IU), the School of Liberal Arts (IUPUI), and the Indiana State Department of Health. She has had her work published in Visible Language, Touchpoint—The Journal of Service Design, and the Journal of Adolescent Health, among other journals. She has presented papers at AIGA Education conferences, SIG-CHI, and the Nordic Design Research Conference.

Michael Weiner MD MPH
Michael Weiner, M.D., M.P.H. is Professor of Medicine at the Indiana University School of Medicine, Director of the Indiana University Center for Health Services and Outcomes Research, Director of Regenstrief Institute's William M. Tierney Center for Health Services Research, and
Principal Investigator of the Department of Veterans Affairs Health Services Research & Development Center for Health Information and Communication, in Indianapolis. His clinical and health-services research focuses on measuring and improving the quality, coordination, and delivery of health services, especially for older adults. He studies the effects of health information and information technology on behaviors, clinicians' practices, and patients' outcomes. He has conducted studies of specialty referral, patient-physician videoconferencing, and other forms of telecommunication to improve health care. Study methods have included cohort studies, clinical trials, surveys, and focus groups. Current research includes the development, implementation, and study of information systems to promote clinical handoffs, management of medications, patient-centered care, health information exchange, and clinical decision support.

Larry Cripe MD
Dr. Larry Cripe Associate Professor of Medicine at the Indiana University (IU) School of Medicine, Service Line Chief, Hematology and Oncology, IU Health Physicians, and President of the Medical Staff for the IU Health Academic Health Center. Prior to changing his research interests to oncologist – patient communication and the end of life health care decisions of people with poor prognosis malignancies, Dr. Cripe served as principal investigator in numerous national clinical and translational trials involving the development of treatments for people with acute leukemia and related disorders. The goal of his current research is to develop computer-supported communication and decision-making frameworks to increase the likelihood that people with poor prognosis malignancies receive care consistent with their preferences and goals. He became the Editor-in-Chief of the NCI PDQ Supportive and Palliative Care Board in April 2015 after serving on the Board for six years. Dr. Cripe is also a published writer. His essays and poetry have appeared in such publications as the Journal of American Medical Association and an anthology “At the End of Life: True Stories about How We Die.” He formerly wrote and read Grace Notes, reflections on living with serious illnesses and the end-of-life that were broadcast on the nationally syndicated radio program Sound Medicine. Finally, he was the Founding Director of the CompleteLife Program of the Indiana University Melvin and Bren Simon Cancer Center. CompleteLife provides psychosocial, complementary, and creative-arts based services for individuals with cancer. In his spare time he enjoys reading essays and seminal works of Western philosophy, gardening, exercising, and spending time with his family.

Facebook as a research tool: Documenting the evolution of mobile phone applications since 2011

Peer Sathikh, ADM | NTU | Singapore, http://PeerSathikh@ntu.edu.sg

Abstract

In this project, two key elements of the development of technology, Facebook, a social media tool, and mobile phones, a portable communication/connectivity tool is brought together in an experiment that was started in 2009 as pilot and full scale since 2011 which continues to date. The objective of this research is document in real-time, how actual and possible uses of mobile phones, which has transcended from the rubber keypad versions to the smartphones of today, is extending beyond its first intentions. The idea came about on reading that people residing abroad bypass stringent laws, national and international, to transfer money to their homes in Africa through the purchase of prepaid cards and offering the ‘pre-paid’ time as ‘money equivalent’ to traders back home who then deliver real money to people in Africa. Today, there are official versions of this such as ‘Sente’ in that continent. With news and clippings appearing across the internet, through various means such as blogs, websites, news-sites, etc., the author realised that all the information, news and bits about the emergence of new uses of mobile phones could be documented through a simple Facebook page. Titled ‘Unique Uses of the Mobile Phones’ the author has been collating information and news about the various ways and means by which smart phones have gone beyond their first incarnation as mobile or cell phones. As an on-going project, the author intends to harvest the data to present the findings in research papers and articles.

Keywords: Facebook, mobile phones, research tool, documenting
Mobile phone has become more than a device for ‘telephony’. Hardly a day goes by without seeing someone or the other holding a mobile phone to their ears, or staring at the screen, be it on the street, in the urban trains, café’s, in the office and at home, everywhere (Figure 1). The word ‘mobile’ according to the Oxford English Dictionary was once used in association with the Latin phrase ‘mobile vulgus’, which means ‘excitable crowd’. Today, ‘mobile’ in the mobile phones signifies that the device is small and light enough to carry it around freely or easily. Looking back at the arrival of mobile phones, statistics show that there were only 34 million users/subscription for mobile phones worldwide in 1993. This has reached 7,740 million as of date in 2017\(^1\), with almost an exponential growth from 2000 onwards as shown in Figure 2. The release of iPhone 3 in 2008 by Apple signalled the arrival of new genre of mobile phones, the *smartphone*, which worked on the paradigm of ‘applications’ or apps. While the regular dial and talk service and short message service (SMS) of the mobile phone was available in smartphones, it is the wide variety of apps and the connectivity to the Internet that suddenly opened the subscribers to whole new world of use for smartphones. Joining iPhone, companies such as Blackberry, HTC, Samsung and LG joined the fray. Together, iPhone and Android spearheaded a complete paradigm shift in the way consumers used mobile phones.

\(\text{Figure 1: Scene inside Singapore’s MRT Trains. Almost everyone has a mobile phone. (Image: Ang Qian Ling, Ourshutterjourney.com)}\)

Added to the new world of apps from Apple and Google, is another leap in social communication in the form of an Internet based social networking site and service named Facebook. Facebook, launched by Mark Zuckerberg and four others on 04 February 2004, became an instant hit with a huge following across the world. According to nextweb.com, Facebook.com had 650 users on 08 February 2004. The number of monthly users of Facebook stands at 2 billion as of mid 2017 according to statista.com². A listed corporation in USA, Facebook seems to be enjoying steady growth since 2008 as can be seen in Figure 3.

On the one hand, smartphones are being used for wide variety of purposes and applications, with thousands of apps being released for/by Apple and Google, which becomes an interesting research study in communication/information morphology of applications for a designer, and would benefit from systematic documentation and archiving of the progress of the different uses of mobile phones in the last decade. On the other hand, Facebook also has evolved from an enjoyable social media pastime, to a more serious service, with thousands of interest groups and with event creators and organisers using Facebook as their main mode of information and communication. How do smartphones and Facebook connect in design research?

This paper presents an ongoing project by the author to use Facebook as a digital and visual archive to capture information and emerging trends, on how mobile phones are being used under different conditions and how companies are developing apps that are unique, taking mobile phones far away from just a phone. There are three distinct points to discuss in this ongoing research project. The first point is the need to document and archive the development and trends in the use of mobile phone, while the second, is the case for Facebook as a vehicle in this research. The third point is how this project uses Facebook to chronologically preserve the news and information on how mobile phones are/could be used, as well as the clippings and visuals of new methods and applications for/of the mobile phones. The paper ends with a discussion on how this project can be taken forward.

**Need to document use of mobile phones**

In a book titled *The Mobile Connection: The Cell Phones Impact on Society*, Rich Ling (2004) writes in the preface, ‘... the mobile telephone is more than simply a technical innovation or a social fad. The examination of its adoption and use and the of the attitude associated with the
device provides insight into some of the broader machination of society. In this process, the sociologist is provided with a rare opportunity to see the domestication of a new technology and its various consequences’. The use of the word ‘domestication’ is interesting in this context, since Ling (2004) seems to see mobile telephone as a wild technology that needs taming. While this book predates many of the apps that were to follow, there is still a sense of where this technology could lead to through the several chapters titled, Making Sense of Mobile Telephone Adoption, Safety and Security, The Coordination of Everyday Life, The Mobile Phones and Teens, The Intrusive Nature of Mobile Telephony and Texting and the Growth of Asynchronous Discourse’. Being part of the first generation of adults that started using mobile phones, the author has had a firsthand experience and the observation from this experience is that, at the early stage of mobile telephony, consumer adoption of a new application or function introduced by (mostly) the device manufacturers was much slower compared to today, where new apps allow instantaneous use. Is this culture change phenomenon common to every culture?

Transitive Culture

In a paper titled Transitive Culture: How ‘global’ product design is changing user behavior, Sathikh et al (2009) point to, ‘... an interesting phenomenon that has been occurring in these (developing) regions of the world, where people, by adapting to these products are creating and finding new ways of using these products, creating ‘transitive culture’ fusing new technology products without disrupting the traditions and practices of their culture’, terming this as transitive culture. Sathikh et al (2009) go on to define transitive culture as, ‘...behavior as it is being cultivated, or cultured, that connects the accumulated experience of the past with the present way of life influenced by artifacts and products of the technology era, which is being socially learnt and transmitted’. This makes it important to document this phenomenon of transitive culture, as rapid cultivators of behavior. To sociologists, behavioral scientist and psychologists, such documentation will aid them in making prediction on the future societal behaviors and norms. This is exemplified in a paper by Campbell (2007) titled Perceptions of Mobile Phone use in Public Settings: A Cross-Cultural Comparison states, ‘These pandemic trends manifest in several aspects of social life, such as teen use of the technology for social networking, new forms of coordination, tensions between autonomy and privacy, and unanticipated consequences of the technology. Mobile phone has shattered many ‘allowed behaviour’ etiquettes constructed by the different societies. How does it do so? Sathikh (2009) in a paper titled Culture in Transition: How ‘global products’ are changing user behavior gives several examples of the how the world of mobile phones is changing culture around the world. This paper (Sathikh, 2009) set the scene for the author’s search for a medium which equally in transition to capture the many varied uses of mobile phones as they occur. This was made urgent by the rapid introduction of ideas such as ‘Sente’ in Africa, where money could be sent and transferred through mobile phones from countries in the Western Hemisphere without going through the exchange controls of the many developing countries in the world (Sathikh et al 2009). The author was awarded a small sum of money as a start-up grant (SUG) in 2009 by the School of Art, Design and Media of Nanyang Technological University, Singapore to investigate on documenting the transitive culture trend of mobile phone uses around the world.
What is required for this project.

Early into this project, the author realised that gathering information on new ways that the mobile phone was being used was through several sources which included traditional newspaper and magazines, on-line magazines, news sites and dedicated websites that post information from various websites. Examples of such online sources are notcot.org, PSKF Creative Intelligence Preview (newsletter@psfk.com), newatlas.com, wired.com, ozy.com and others. Initial attempt to document the information/data in pdf files from these sources proved to be too cumbersome.
Moreover, the author felt that this research is not about collecting data for own consumption, but should be shared with as many people as possible across the world. Tedious computer based information storage and retrieval meant several layers of navigation before anyone could reach to the location that they were searching for. An avid user of Facebook since 2007, the author decided to experiment with Facebook as a potential vehicle for storing and retrieval of information and data as they arrive.

Facebook as a vehicle in this research

Facebook today, leads the world in social network sites (SNSs). According to Smock et al (2011), ‘Early work showed how Facebook was used to connect with previously existing social connections, rather than make new connections’. Today, Facebook allows for many different uses with the user interface screen as a basis to take advantage of the various new features and interaction, allowing for social connections beyond the original small circle of friends. The author forms a closed group for the undergraduate students who are doing their final year project (FYP) under his supervision as seen in Figure 4.

Facebook also has a user friendly ‘face’ and interaction tools that makes it easily adoptable for even people who are not familiar with SNS. With the need for a dynamic documentation of the rapid roll out of new uses for mobile phones almost every day, the question is, can Facebook play an important role in this? Is there a parallel in the use of Facebook for such purpose? Good (2013) in an article titled From scrapbook to Facebook: A history of personal media assemblage and archives provides the answer through her, ‘research on print-era scrapbooks and contemporary social media to highlight commonalities between the two formats, both in terms of the practices they have historically promoted for users, and the methodological challenges they produce for researchers’ (Good 2013). Based on the observation that scrapbooks in its different forms and format provide a repository of what a person is thinking, doing or planning, Good (2013) argues that, ‘... scrapbooks and social media can be conceptualized as sites of personal media assemblage and personal media archives, a designation that highlights the simultaneously social and archival dimensions of each form.’
Further, ‘Like scrapbookers in the print era, today’s active users of Facebook and other SNS leave mediated traces of the events and social encounters that shape their lives (Good 2013)’. In other words, archiving of the progress of the use of mobile phone affords a level of mediated trace about the period and in what context (social, economic, political, cultural, medical, etc.) each particular use was conceived. This would allow for many possibilities in presenting the documented progress. For example, say, the intention is to chronologically document and analyse a pattern in the development of apps for a certain medical condition, all
it takes is to run through the Facebook page and ‘harvest’ all the relevant application that have been archived in that page since 2009. This is the type of ability that this project warranted in this project.

Figure 4: Example of Facebook Closed Group

Documenting the evolution of mobile phone applications

After studying the advantage of Facebook as a repository for documenting the evolution of mobile phone application, a Facebook page titled ‘Unique Uses of the Mobile Phone’ (UUMP) was started with the author and a student research assistant, Kailin as administrators in 2009. Within days the page was populated with postings with links to the source from which each information was taken from. Invitations to ‘like’ the page was sent to Facebook friends with a request to also send in links and lead/information that could be posted in the UUMP page. The UUMP has been active since 2009 (when it was piloted before going full scale in 2011) and continues to build content that is being archived electronically. The UUMP page’s ‘about’ page as seen today is shown in Figure 5.

Figure 5: Unique Uses of the Mobile Phone page in the Facebook
Figure 6 shows a collection of random screen capture to highlight the different topics/areas that the posts represents.

This documentation cum archiving is an ongoing project with the author spending at least an hour every day to read through all the feeds and inputs to select those that are new and unique before posting them into the UUMP Facebook page. A posting can reach anywhere between 10 to 100 people as seen from the information on the screen. A simple posting such as for an app for roadside help in towing and repairing a car on the streets or highway could reach more than 250 people with the post being forwarded and re-posted within their friend circle and so on.

Discussion

What can be done with the archive build-up of posts about the evolution of mobile phone applications? For one, the information is not only written but is also visual giving an opportunity for those researching on mobile phone apps and uses to refer to. The sources of the information are also easily traceable. This archive gives researches to harvest/mine the data, survey, analyse and categorise the evolution in several directions and topics. For example, one can see the evolution of medical apps and how mobile phones help in healthcare by mining for all postings related to health and medical apps. Similarly, use of mobile phone and apps to address social issues in different countries, during different period can also be mined, analysed and charted. For a researcher interested in looking at the technologies behind the apps and how they have evolved, this page becomes a data field to harvest. Study of what areas and apps have survived and what have not been successful is also possible through this Facebook page. As one pores over the past postings and the growing postings, it is possible to conceive many ways to analyse, represent and interpret the information and data available. The UUMP Facebook page thus becomes a unique and dynamic data accumulator for research in many fields and in many ways, shows the usefulness of Facebook in serious research.
Conclusion

What started as a fun pilot exercise for the author and his student researcher has grown into a field rich enough to harvest for information and data. Besides being an amusing almanac for the curious, the UUMP Facebook has shown its potential as resource rich minefield. The author intends to open this up as possible masters level study for design or design history students to organise, categorise and show the development of what could be the most important products of the 20th century, namely the mobile phone. The Facebook page is open and hence it is hoped more and more researchers of design and related fields visit and contribute to this digital repository. The author also wishes to invite everyone to send in information and link about interesting and unique uses of mobile phones. It is hoped that more research initiatives using Facebook as a research tool or vehicle is possible in the future.

Design pedagogy in symbology: denotative and connotative interpretation

Sang-Duck Seo
Associate Professor, Graphic Design & Media
Department of Art, University of Nevada Las Vegas (UNLV), Las Vegas, USA

Abstract

This study introduces a new perspective on the design pedagogy in learning symbol design. A new experimental discipline implemented by the design methods demonstrates positive learning outcomes for students on the development of symbol study. Understanding denotative and connotative interpretation in visual literacy is essential in order to convey not only a clear message but also distinctive recognition as the nature of symbol quality. Students executed design experiments with design theories and methods for understanding design fundamentals of the denotative symbol and explored a matrix table for cultivating connotative symbols. This pedagogical strategy applied to the expansion of visual concepts with progressive experiments on each stage: 1) analyzing perceptive characteristics, 2) simplifying visual construction, 3) developing a visual concept with connotative meaning, and 4) configuring visual balance and enhanced quality based on design principles. With examples of student outcomes, this paper explains an analysis of functional expression and interpretation applied by design methods. This study discovered that earlier teaching of design fundamental disciplines with theories and methods in the graphic design major gave students better opportunities to pursue their further study more effectively and productively.

Keywords: Symbol study, Visual literacy, Design pedagogy, Design methods

This paper aims to demonstrate an empirical study of the design pedagogy in denotative and connotative symbol study. The study was implemented by the sophomore level of graphic design students and the instruction focused on design theories and methods for helping students to improve their design proficiency of visual literacy. This study was also to cultivate effective and productive learning outcomes from a pedagogical strategy in which students were able to expand critical thinking ability from the problem-solving process in the discussion with the interpreting and understanding visual language and communication.

Literature Review

A symbol study is a significant discipline of graphic design major in learning fundamental visual language as to how it interprets formally and conceptually. Academic curricular activities are typically comprised of creative exercises and practices related to visual literacy for design students. While many design pedagogy introduced a logo or brand identity as a case study, students have difficulty to accomplish the successful goal of understanding “how to” and “what to” for developing visual concept. According to the arguments between “seeing as” and “seeing that” while designers are working on figural properties in the sketch (Purcell & Gero, 1998), it is significantly considerable to learners as how they improve their proficiency
of visual language beyond vocational skill sets in visual creativity. Many designers in the professional fields still rely on “intuitive decision” during the creative process (Maggie Macnab, 2015). However, the example of the logo design shows the visual attention on multiple levels: symbolic, metaphoric and semantic (Figure 1).

![Figure 1. Valle Encanotado Farmers logo (Source: visuallanguage.com)](image)

In contrast to “feels right” in the intuitive decision making process from the experienced designers, learners (students) still need to acquire knowledge and experiences to be a great thinker. Moreover, art needs to be considered as a visual literacy of the syntax meaning that are facts, principles, and rules learned through an educational discipline (Hausman, 2008). As symbols and metaphors definitely existed on the process of development for visual concept, focusing on the denotative interpretation of inherent meaning is conventional, however, identifying and interpreting symbols is considered as a visual connection to the connotative level of meaning (Barthes, 1977; Hasenmueller, 1978; Serafini, 2011). Symbol design also applies to a variety of visual metaphors with different role and responsibility. As a symbol appeared by elements of iconic design, it should keep in simple, relevant, traditional, distinguished, memorable and powerful (Airey, 2010). A successful symbol provides visual quality with an effective balance between clarity and uniqueness (Hsu & Wang, 2005). Any abstract form combined with some attributes of both icon and symbol should be considered as not only being simple and clear, but also being in a “self-consciously” abstract way appearing on symbolic qualities (Samara, 2014; Arnheim, 1969; Arnheim, 1974).

**Research Methods**

According to the nature of the academic environment in liberal arts in which students’ learning outcome requires both comprehensive visual literacy and proficiency of design ability, the discipline of the symbol study in the beginning level of graphic design major has focused on the design theories and methods instead of placing the subject matter on the practicum basis. The pedagogical strategy demonstrates how students approach the development of visual concepts with progressive experiments on each stage (Table 1).

<table>
<thead>
<tr>
<th>Stage</th>
<th>Learning Activity and Implementing Creativity</th>

<tr>
<td>S3</td>
<td>Developing a visual concept with connotative interpretation.</td>
</tr>
<tr>
<td>S4</td>
<td>Configuring visual balance and enhanced quality based on design principles.</td>
</tr>
</tbody>
</table>

This pedagogy was implemented in the design studio, “GRC 320 Design Methods & Research” which is in sophomore level of the current graphic design program at UNLV. As
one of the learning design methods in the course, this assignment began with a lecture to discuss about fundamental design theories and methods with analyzing design examples in abstract symbol structure such as logo, icon, infographic, sign, etc.

Statement of Assignment

The assignment was comprised of two different tasks: delivery of the semantic distinctions between denotative and connotative consequences satisfied with clarity and uniqueness of symbol quality. Each student was given a subject matter by other students so that they were able to practice creative problem-solving beyond one individual preference. Randomly given each attribute provided students to consider it as how a symbol set can depict different visual concept integrating with visual metaphors in connotative consequences.

Preliminary comprehension for understanding a nature of symbolology

The assignment began with discussion about how to simplify the visual image. With a draft thumbnail sketch, regardless of the quantitative results, a group critique occurred for discussing a lack of visual quality based on clarity of visual information. Table 2 shows a common procedure of producing an abstract of the object. Form is not yet described in any specific details, but it is clear to perceive a fundamental distinction of the character as “Poodle” from other breeds. Depending on the object that each student dealt with, visual description was varied with graphic identifications. As a graphic symbol requires presenting a visual characteristic of the object that can be discovered by different views, students collected various images/photos from different views and analyzed significant characteristics on gestures and poses. This process allowed students to expand visual characteristic to be diverse and unique for the visual concept, moreover, the result of initial ideas appeared recognized visualization with meaningful definition.

Table 2. Common procedure of understanding abstract for clarity

<table>
<thead>

<tr>
<td><img src="image1" alt="Poodle" /></td>
<td><img src="image2" alt="Poodle" /></td>
<td><img src="image3" alt="Poodle" /></td>
</tr>
</tbody>
</table>

Table 3 addresses the second step for transforming a visual imagery with more accurate characteristic and impact of visual abstract that established symbolic construction with understandable visual definition. Students could be able to narrow down the decision-making process in developing visual concept with more enhanced abstract form in consistency through the visual construction. This result produced a great discussion for students to be realized that the visual abstract is not only required by visual clarity, but also unique identity distinguished with other decisions and visual concept.
Table 3. Analysis of Visual Characteristic for uniqueness

</tbody>
</table>

Implementation of design methods for denotative interpretation

With completing a practice on the comprehension of basic symbol methods, students moved the second stage for development of the denotative symbol set based on the subject given by each other. Each student executed the same task from the previous practice to develop a total of five symbols and they produced a vector image for the clearness of visual quality (Figure 2).

![Figure 2. Development for denotative symbol set](Image)

According to the discipline with understanding abstract form, the final denotative symbol set required to be clear with understanding the visual characteristics. Any judgement of debating between clarity and uniqueness for the symbol quality left for the final outcomes in which all symbols need to appear with both satisfactions and effectiveness in the connotative consequences. However, the abstract form was considered to describe with line and mass for the high contrast in visual construction (Table 4).

</table>
The decision to apply when and how to use line and mass depends on the personal references, allowing many possible ways to come up with different variations in the design methods. In addition, contrast in design principle is an essential element to symbol design due to the functional expression for readability, legibility and comprehension when the symbol appears as logo, brand identity or signs. If a symbol does not carry on enough contrast in visual information, students were asked to examine a line thickness in the denotative symbol set.

**Implementation of design methods for connotative interpretation**

For the implementation of design methods for connotation, each student wrote three attributes which required not to be specific relations with their subject matters. Students were encouraged to propose all different objects which may produce a visual abstract from organic to geometric in visual characteristics, less to more in visual information, and objective to subjective in preferences. With given attributes exchanged by anonymous assigners, students integrated those words with denotative results in a matrix table referring to each visual characteristic. In this experimentation, there were some considerations for developing visual balance between clarity and uniqueness:

1) how much visual information can be controlled in a way two visual characteristics included or excluded?
2) what role or function of attributes do you perceive for connotation?
3) how do we utilize two visual structures equally adopted into another?

Moreover, these questions supported design methods to their experimentation in connotative design methods. Students developed visual concepts for the connotative symbol with three design methods, however, visual experimentations with three attributes were not limited to explore more or less effectiveness of the visual balance between subjective perceptions and objective descriptions. Table 5 describes three different demonstrations per each method. The solution appeared as successful outcomes with visual balance between clarity (denotative interpretation) and uniqueness (connotative interpretation).

Discussion

The final symbol set in a matrix table required a total of 15 symbol sets. The final solution was not required to apply any color yet due to the discipline focusing on visual construction of symbolic fundamentals more precisely. In a new pedagogy of implemented design methods for symbol study instead of intuitive thinking and decisions, I found that students excelled creative performance successfully beyond visual aesthetic concerns. Among a total of 16 student works, this paper brought four different examples to the discussion and findings. First, we learned that considering more than one visual characteristic could identify unique visualization, but we found that some attribute has a difficulty to be associated with inherent characteristic when the object is not clear to perceive visual identity. Figure 3 overall shows decent quality of symbol set, but two attributes, “clothespin,” and “rose” were conflicted to utilize an entity of the tiger symbol.

Among the 15 examples, most students responded to three examples. The red highlighted on the table below were most successful to be satisfied with the visual balance between clarity and uniqueness.
As earlier discussion regarding the visual impact in symbol, we appreciate the great amount of visual contrast such as line and mass. Figure 4 shows an effective adjustment with line thickness combined with mass form by other attributes while denotative symbol of the octopus illustrated with only certain line thickness. We found that a lack of visual contrast was not strong as much as we perceived a variety of differentiate section on connotative symbol set. A majority of students responded to three examples highlighted in red on the table were most successful to be satisfied with the visual balance between clarity and uniqueness. The solution was positive to have a least one of each attribute criteria. From other feedbacks, the first attribute allowed the subject to be more unique in terms of the unexpected visualization from the typical visual thinking process.
As the matrix table allows students to explore more inclusion with the attribute as a primary entity, we found that the result of visual combinations between two characteristics was not necessary to be equal in terms of unifying visual concepts and identities. Figure 5 shows the successful visual unity and harmony, especially distinction of visual concepts from one to another characteristic. The result of each individual symbol describes an interesting visual information clearly at the level of visual balance between clarity and uniqueness. However, we also found that the same problem with lacking of visual characteristics was not possible to understand contents and visual identity. The last column of the table appeared as a difficulty of visual clarity, but it became a conceptual structure with each attribute. We found that attributes with “QR” and “Atom” made a ray as the most interesting visual concept and unique aesthetic in the symbol set. Students learned through this example that applying attributes into breaking and manipulating a subject entity with remaining denotative meaning would be the best way to experiment for finding a connotative symbol.

A few students had a difficult time implementing the design methods in this study. While they were not fully familiar with design methods as how to develop the concept and idea in a critical thinking process, their solution showed a significant problem with both design quality and function. This phenomenon underpins that a lack of visual perceptions in an innovative level was not possible to improve design ability in learning academic disciplines. Figure 6 is an example of comparison between “Final solution” in the critique and “Revision” after the student fully understood design problems based on three questions of consideration for the connotative interpretations. The “Final solution” has poorly lost fundamental meaning of the object, but more difficult to understand when the attribute was not considered as role and function in design method. The “Revision” obviously appeared effective improvements of visual literacy and proficiency in learning objective. As a result, we found that students became more confident to expand critical thinking ability and to approach an effective decision making process to arrive at the best option as how to use an attribute for connotative interpretation.
Conclusion

In conclusion, this pedagogical symbol study implemented into design method discipline brought an effective learning outcome in sophomore level of graphic design major. With the tangible solution and design outcomes at the end of the final critique, many students were more confident with developing visual concepts for an efficient balance between clarity and uniqueness.

Students, moreover, will face with many subject matters in design creativity through upper divisions and professional fields. This design method will help them to reach the goal of successful outcomes with any type of symbol design within limited schedule and time consumption. While there was a limitation with measuring the effectiveness of disciplines compared with other practical exercises for the symbol design, we believe that students will execute their creativity more productively and professionally. In addition, with various practices of design principles, students understood visual quality of symbol much better based on unity and harmony. This study definitely distinguished vocational discipline of practical exercises and students perceived the academic importance with research and methods through all the design study and activity as a team. For the future study, this design method in symbol study will expand additional parameters of attribute’s roles and functions in a matrix table in where students will be able to develop their critical thinking ability in visual communication.

Abstract

The Japanese government has planned by 2020 to introduce the Finnish Neuvola System, a fundamental social childcare system that covers the period of pregnancy to child care. The purpose of this research is to clarify the conditions for high quality of Neuvola service, comparing childcare of Finland and Japan. First, the social systems of Finland and Japan, legal actions and other related social backgrounds are covered. Following this, the results are analyzed. Secondly, the results of interviews in Finland with Neuvola public health nurses and three typical Neuvola users, including a father, mother, and pregnant woman are presented. As a result of survey, six conditions were identified as the basis of Neuvola services: personal health checks, facility preparation, pleotropic care, communication through mutual dialogue, customized information and management of service provider quality. In a society where nuclear families are increasing, it is harder to care for children without someone’s support. In comparing Finnish and Japanese childcare systems, the Finnish system perceives childcare as a social matter. In the Neuvola System, people are always open to discuss about any worries or queries. In Japan, the system is closed toward personal matters and private treatment options are not adequate. This is a major factor in larger problems that exist in the Japanese system. The results are discussed in relation to previous studies of participatory roles in social health care services in the Japanese government and users of these services, leading to the proposal of a Japanese childcare service design.

Keywords: Service Design, Welfare, Social, Childcare, Government

Declining birth rates are a serious social problem in most developed countries. The Japanese Cabinet Office now requires that local governments throughout Japan put in place a “project for comprehensive support of the child-raising generation” by 2020. As a reference model, we adopted and promoted the Neuvola public childcare support system of Finland, which involves childcare from pregnancy onwards. Neuvola is literally translated as “a place for advice,” but is synonymous with “maternity clinic.” Whether the comprehensive support project for the child-raising generation will halt the declining birth rate in Japan depends on whether the actual service is user-friendly and preferred by the service provider.
Purpose

In this study, we aimed to compare the childcare support services of Japan and Finland and extract commonalities and differences between them. Further, on the basis of such differences, we aim to reconstruct Neuvola from the perspective of service design, and identify the conditions required to provide quality support at Neuvola. (1)

Based on the conditions found, the final aim of our whole research was to elucidate the childcare service needs suited to the actual circumstances of the Japanese population.

Research methods

Our literature review involved (1) investigation of Neuvola, (2) investigation of previous studies regarding the design of Neuvola, and (3) comparison of the social systems for childbirth and childcare in Finland and Japan. A field survey in Finland involved (1) interviewing Neuvola service providers, (2) interviewing Neuvola service users.

Literature review 1: Investigation of Neuvola

Neuvola refers to support facilities offered in Finland for one-stop childcare from pregnancy onwards. Established in 1944, it has more than 70 years of history and its facilities are used by 99.8% of the parents and children born in Finland. (2) The service is credited with a marked rise in the total fertility rate in Finland (1.9 in 2012). Neuvola provides a means for the mother, child, and wider family to consult the same public health nurse at a single location. This “Neuvola nurse” is then their family health specialist from pregnancy until the child entered school and provides a range of services (e.g., medical check-ups) to all family members, irrespective of nationality and family status. If needed, the Neuvola nurse also makes referrals to specialist services. Broadly, the Neuvola service is divided into prenatal “maternity Neuvola,” and postpartum “children’s Neuvola.” All services during both periods are provided free of charge.

Literature review 2: Investigation of previous studies

Many studies have been conducted concerning the effects of Neuvola on nursing and welfare, but there are few studies concerning service design, especially comparing childcare support in Japan and Finland.

Literature review 3: Comparison of the social systems for childbirth and childcare in Finland and Japan

1. The social care system for childbirth and delivery in Finland

Finland has a long history of contributing to maternal and child health after having been declared an independent nation in 1917. The first Neuvola service was established for children in 1922 but was institutionalized in 1944 to include expectant and nursing mothers. (3) Since then, local governments have been obliged to establish Neuvola services, which led to nationwide popularization after 1945.

Regarding social security, a maternity package was legislated in 1937. As part of this package, mothers received 140 euros in cash or were provided with a childcare package as well as 263 days of leave. This leave includes 105 days of maternity leave for use exclusively
for the mothers’ pre- and post-partum and 158 days of parental leave that can be taken by either the mother or the father. To provide economic security during this period, approximately 70% of the income for this period is paid for immediately prior to taking leave\(^4\).

From pregnancy until the child entered school, services could be accessed at regional Neuvola centers by children and their family. Neuvola provides prenatal check-ups, periodic health checks for infants, counselling, and home visits, among other services, with childbirth typically being performed in maternity hospitals.

2. The childbirth and childcare system in Japan

Child welfare before 1945 empowered the state to protect children in difficult situations; however, the Child Welfare Act of 1947 established child protection as an official welfare policy.\(^5\) The “1.57 shock” of 1990 triggered the Japanese government to investigate countermeasures for the declining birth rate.\(^6\) In 2013, the council for countermeasures against the declining birth rate focused on the need to improve and strengthen measures for continuous support of marriage, pregnancy, childbirth, and childcare. From this, “the project for support of the child-raising generation” was created.

As part of the social security system, covered by health insurance, 420,000 yen is granted per child in a lump sum after the birth of the child.\(^7\) Furthermore, a maternity allowance is given for childbirth to the mothers with health insurance if their wages are not paid for a period from 42 days before birth to 56 days after birth. This sum is two-thirds of that person’s standard daily wage, per day of leave.\(^8\) Some maternity leave payments are covered by employment insurance if certain requirements are met and are paid at a rate of 67% of the daily wage at the start of the leave multiplied by the number of days’ leave taken from birth until the child is 1 year old.\(^9\)

Although there are differences between local governments, healthcare services in Japan are broadly structured as follows. Prenatal check-ups and childbirth are managed by obstetrics and gynecology departments. For these prenatal health checks, local governments distribute tickets for women to attend 14 health check-ups during pregnancy. Infant health checks and maternity education are conducted by doctors and public health nurses at health and welfare centers, while infant vaccinations are performed by pediatrics departments. Mass health checks are conducted at health and welfare centers on days determined by the local government. Infant check-ups primarily comprise medical care child development screening.\(^10\) Home visits are made by municipal public health nurses and midwives.

Field survey1: Interviews with public health nurses, participants and procedure

I visited the Tapiola Neuvola in Espoo, Finland, and conducted interviews of two nurses regarding the services provided and the facility. One participant was a senior public health nurse (a woman in her 40s) who managed public health nurses at the facility. The other nurse was a woman in her 40s who carried out the general duties of a public health nurse, and in particular, took care of many foreigners.

I first benefitted from a private tour of the facility and were able to inspect the service while receiving an explanation of the instruments and equipment used by the nurses. The field survey was then conducted on February 24, 2017 (9:30–12:00) at the Tapiola Neuvola facility. The interviews focused on the types of services provided and on the details of Neuvola.
operations/management that are not known to the service user.

Field survey 2: Interviews with Neuvola service users, participants and procedure

I conducted interviews with Neuvola users on February 24, 2017 (13:00–15:00 and 17:00–18:30). Three participants were included: female A, female B, and male C. Female A (age 32 years) was 37 weeks pregnant with her first child at the time of the interview, and both the mother and the child were healthy. Female B (age 33 years) was a mother with two infants, one was 0-year-old and the other was 1-year-old. The first infant was delivered by emergency Cesarean section and the second infant was delivered naturally. She used her closest Neuvola service for both the children. Male C also had a 0-year-old and a 1-year-old infant, and he used the Neuvola where his wife and children received health checks. Female A was interviewed in Helsinki (the largest city in Finland) regarding the pregnancy period, while participants B and C were interviewed in Espoo (the second largest city in Finland) regarding the childcare period from 0 to 6 years.

Participants were asked to complete a timeline of their personal experiences (Figure 1), using the Shostack (1984) service blueprint(11) that has been shown to be an effective technique for assessing service design. The vertical axis is divided into the points of view of the user experience and provided services from Nevola. The horizontal axis gives a timeline from pregnancy until the child entered school. The event timeline helped structure interviews regarding the services provided at Neuvola, how users perceived those services, and any problems or possible improvements.

![Figure 1: Event timeline](image-url)
Results

Literature review

Childcare support services in Japan and Finland were compared by dividing them into pregnancy and childcare periods (Figures 2 and 3). In the tables, the horizontal axes represent time and the vertical axes are divided into the service provision of Finland and Japan.

Figure 3: Comparison of services during the childcare period
A common area between the Japanese and Finnish services was the provision of regular childcare support after childbirth. However, there were several differences. In Finland, individual health checks were conducted at the same Neuvola. Furthermore, there were fewer health checks by doctors, and some practices traditionally performed by doctors were performed by public health nurses. In contrast, services in Japan were divided by the period and content of the check-up, and examinations were typically received at different facilities. Furthermore, prenatal check-ups were performed on an individual basis, whereas postpartum infant health checks were performed as mass health checks, with most medical care for children being provided by doctors. Field survey1: Interviews with public health nurses

The interview results are summarized in Table 1.

**Table 1. Services provided at Neuvola**

- **Venue**:
  - Consultant rooms are equipped with a sleeping area, shower, and sink.
  - Consultations are performed in a relaxing and comfortable atmosphere.

- **Care**:
  - Consultations are performed by public health nurses.

- **Mental health care**:
  - Consultations are performed in a comfortable and relaxed environment.

- **Education for the family**:
  - Educational activities are provided for parents and children.

- **Accommodating**:
  - Accommodation is provided in a comfortable and welcoming atmosphere.

- **Consulting hours**:
  - Consulting hours are from 9 am to 5 pm.

- **Public health nurse and mother**:
  - Public health nurse and mother relationship is established during the prenatal check-up.

- **Referrals and cooperation**:
  - Referrals and cooperation with specialist facilities are established during the prenatal check-up.

- **Information and services**:
  - Information and services are provided in a relaxed and comfortable setting.

- **Quality of the service**:
  - The quality of the service is evaluated by public health nurses.

- **Conclusion**:
  - The conclusion is provided in a comfortable and welcoming atmosphere.
a) Venue
   Each public health nurse worked in one room, allowing all procedures to be conducted in a single place with minimal disruption. To facilitate visits, family-friendly spaces were provided with a play room and chairs in the consultation room. Health checks were conducted by appointments to avoid congestion. The private rooms seemed to allow users to relax without worrying about other people watching.

b) Care
   Care was provided in three forms at Neuvola. 1) Financial care, which involved providing free services and a maternity package (e.g., baby clothing and other items). 2) Mental health care, which involved the public health nurse providing emotional support and counselling. The recent inclusion of comprehensive health checks allowed nurses to support the entire family. 3) Physical care, including measurements, urine tests, blood tests, and vaccinations, which were performed by public health nurses and doctors.

c) Communication
   More than 90% of the families approached Neuvola for the children entering school because care was provided by the same public health nurse and because Neuvola has high social recognition. Neuvola provided health checks and information to all individuals regardless of nationality and family circumstances. If needed, Neuvola offered consultation through specialist institutions.

d) Information
   Neuvola respected the individual requirements of family, providing customized information based on circumstances. All information from health checks was consolidated in an electronic system to allow access from any Neuvola, which was an effective means of reducing the burden on users and public health nurses.

e) Quality of the service provider (public health nurse)
   In Finland, public health nurses are specialists who receive specialist education in maternal and child health, requiring completion of a 4-year specialist course at a higher education facility. There are national regulations for the assignment of public health nurses, and once assigned, they must complete ongoing training, which we found led to improved quality. At the Tapiola Neuvola, each nurse managed approximately 30 pregnant women and 230 children. However, while the same services were offered nationwide, there was a possibility of individual differences because health checks are usually performed by one public health nurse.

Field survey2: Interviews with Neuvola service users
   The results are summarized in Table 2 and can be detailed as follows.

a) Venue
   All individuals were satisfied with the ease of access, and typically felt that these venues were places where they could relax.

b) Care
   Users interacted closely with the public health nurses, such that even female A felt knowledgeable and comfortable during the process of childbirth. The users each reported calling the Neuvola service several times to seek advice after conception. They were satisfied not only with the physical care provided for mothers but also with the mental health care provided for families.
c) Communication

Anxiety about childbirth and childcare was alleviated through dialogue with a public health nurse. One-on-one exchange enabled individualized responses, with some users requiring different levels of support. In Finland, pregnancy and childbirth are typically performed through cooperation between the couple, so the couple was generally supported socially by Neuvola rather than by their parents. The public health nurse questioned the family at the health checks, and family participation was recommended at that time.

d) Information

All three users sought information from reliable specialists, such as doctors and public health nurses, that was suited to the individual’s circumstances. Information from the Internet was considered biased and potentially unreliable because it could not be adapted to the individual’s needs.

e) Quality of the service provider (public health nurse)

The users were satisfied with the care provided by and the awareness of their public health nurses. Furthermore, relationships of trust were built due to care being provided by the same public health nurse (e.g., users trusted that their secrets would be kept). However, Female A commented that she was unsatisfied with the services received because they did not have compatibility with the public health nurse. At Neuvola, the public health nurse in charge was the only contact point, and therefore, we found that an alternative contact point should be prepared in case of problem.

+ Positive, - Negative
Discussion

In this study, we performed a literature review and field survey to clarify the factors underpinning the provision of quality childcare support services at Neuvola. Here we discuss each item that we identified.

1. Personal health checks

Health checks in Finland were performed on an individual basis from pregnancy until the child entered school, and conversations were based on private discourse about the couple’s relationship, the surrounding support, the presence or absence of domestic violence, and the user’s financial situation. Users gained peace of mind and answers to their questions at individual health checks. This was not only an advantage for the user but also for the service provider, because it helped them gain deeper understanding of individual situations. We think this approach helped practitioners detect and resolve problems before they became significant issues.

2. Establishment of the venue

Family participation was recommended in Neuvola facilities, with playrooms and chairs being provided for the whole family. Furthermore, the services were completed at a single facility, resulting in minimal burden and confusion for the user. This may account for the high rate of participation in the Neuvola service.

3. Pleotropic care

In Japan, doctors provide medical care for children. However, this is not a holistic approach because no matter how healthy a child is, it is difficult to raise the child unless the whole family is mentally and physically healthy. Although the approach of Neuvola to provide physical, mental, and financial support to the entire family may generate extra work, when looking at the growth of children in the long-term, the approach may actually be more effective.

4. Communication through mutual dialogue

The core service provided at Neuvola was communication. Ensuring sufficient time to talk meant that everyone could receive advice about individual concerns and could ask questions regarding their children and family. As a result, public health nurses could resolve problems early and users appeared to gain peace of mind by having access to a reliable source of advice (i.e. the public health nurse). This created a relationship of trust between the provider and the user.

5. Customized information

Users sought services that were not uniform but that were instead suited to the needs of the individual. Indeed, questions, anxieties, and problems that arise during pregnancy and childcare may require different approaches. Therefore, one user might only need one-way information provided by books and the Internet; but, if misjudged by the user, this could increase anxiety and problems. Nevertheless, we believe that providing accurate advice to the user enhances their peace of mind and it is best delivered directly by the public health nurse.

6. Management of service provider quality

At Neuvola, users were essentially taken care of by the same public health nurse for 7 years from pregnancy until the child entered school. Communication over this period was the reason for the relationship of trust; however, we believe that this is underpinned by an environment where public health nurses can keep working along with specialist education as well as legal and work systems.
Conclusion

As a nuclear family becomes the norm, it is difficult to raise children without support from external sources. Therefore, the provision of support that addresses the individual questions and problems of the patients (e.g., Neuvola) is an important public service. Given that birth rates are expected to continue to decline in Japan over time, the improved fertility rates in Finland and the positive responses from user interviews indicate that services that provide care for the entire family are important to the child-raising generation. The question as to whether childcare is facilitated at social and individual levels will be key to dealing with the declining birthrate in Japan. Improving social services could lead to a society in which two or more children are born per family, with the peace of mind that appropriate care will be provided for them.

Future tasks

Introducing a Neuvola-style childcare support system in Japan would be met with obstacles and difficulties due to differences in social systems. However, there remain many facets of the Neuvola system that could be adapted and used to improve the quality of the Japanese childcare support services. We plan to conduct a survey of the childcare support services offered in Japan to help understand the current situation, before designing a Neuvola-like service that could work in Japan.

Abstract

To limit the harm and damage caused by river flooding, signs to indicate dangerous water levels are placed along the river, particularly where there is a danger of overflow. However, the general level of awareness of such signs is low. In this study, we examined ways to efficiently convey information that people have little interest in and find difficult to understand.

Dangerous water levels are quantified and communicated using colors to indicate the degree of danger, and this information is conveyed to the public with signs on bridge piers and slopes. Various other measures are also employed, e.g., adding evacuation pictograms to signs, displaying signs separate from graduated water level indicators, and providing detailed information via the river office website. In addition to using Internet channels such as websites and Facebook, it is common to create and distribute pamphlets and other kinds of printed notifications to communicate such important information as widely as possible. Nevertheless, information that is essential in an emergency but unnecessary at ordinary times is difficult to communicate widely and effectively, even if all these measures are taken. This is because even if people accept that such information must be understood, they remain uninterested and find the information difficult to understand. To solve this problem, we created a story featuring mascot characters for each danger level. This story, presented as a picture book, overturns the conventional attitude toward such information. We thereby developed a medium for communicating important information in a way that better captures people’s interest.

Keywords: River Sign, flood information, Means of provide information

Research Method

Through an Internet survey, case survey, and by interviewing river managers, we clarified the roles of dangerous-water-level signs on rivers. Then, we studied the general public’s knowledge of the information shown on such signs, and analyzed their awareness and understanding of them. Finally, we proposed a method of widely disseminating dangerous-water-level information which, according to the above analysis, is disregarded by many people.
**Dangerous-water-level signs on rivers erected by the national government**

In response to severe flooding and sediment-related disasters, generally caused by torrential rainfall, which has occurred increasingly often in recent years, in 2006 the Disaster Prevention Terminology Improvement Study Committee proposed the creation of an effective flood-related, etc., disaster-prevention information system. In the past, river managers placed dangerous-water-level signs at rivers in order to visually observe water levels during periods of concentrated rainfall; however, the Study Committee highlighted various issues concerning this system, including the fact that the conventional disaster-prevention terms are not easily understood by the public. To overcome these challenges, the committee advocated improving terminology, setting danger stages based on the degree of danger posed by certain water levels, providing easily comprehensible information for the general public, and summarizing the actions that people should take at each danger stage. The dangerous-water-level signs presented in the proposal show five stages of danger. Danger Stage One is colored white, with the boundary between stages one and two representing the inundation-warning level; Danger Stage Two is yellow, with the boundary between stages two and three representing the evacuation level; Danger Stage Three is red, with the boundary between stages three and four representing the inundation-danger level; Danger Stage Four is also red, with the boundary between stages four and five representing the inundation-occurrence level; and Danger Stage Five is black (Fig. 1).

![Figure 1 Danger stages for water levels and guidelines for action](image)

**Present state of dangerous-water-level signs in rivers**

In cooperation with the River Management Section, Kyushu Regional Development Bureau, Ministry of Land, Infrastructure, Transport, and Tourism, we surveyed the placement of dangerous-water-level signs throughout Japan. We also conducted an
interview survey of river managers to determine the present state of these signs. Dangerous-water-level signs are placed at locations where severe flooding has previously occurred, locations at high risk of inundation through concentrated rainfall, etc., and at water-level-observation stations. Further, such signs are rarely placed independently as new structures; generally, nearby bridge piers, where the colors can be seen from river banks, are painted with the danger stages. Meanwhile, other structures used include the top, side, or base of the handrails of riverside steps or slopes and water-level-observation stations. Independent signs are rare because managers prefer as few structures as possible on rivers; this is because driftwood, refuse, and other flotsam can catch on such structures, forming weirs.

Table 1 Examples of typical placings of dangerous-water-level signs

</tr>
</tbody>
</table>

Frequently employed methods of indicating dangerous-water stages are painting the colors over the entire area of the structure in question, such as the whole surface of a bridge pier; painting only lines showing the boundaries between danger stages; and setting a fixed area and painting the colors for each danger stage within this area. Another characteristic method is to show evacuation pictograms at the location of each danger stage; these advise residents of the water levels at which they should begin evacuation activities. Further, the information shown by the dangerous-water-level signs has also been occasionally supplemented by installing notices explaining the signs, or ensuring that people can easily check water levels at night, such as through installing lamps that illuminate when river levels become threatening (Table 2). It must also be considered that, during torrential rainfall, the
surroundings are unavoidably darkened and visibility is reduced, and this is another reason danger stage boundaries must be clearly distinguishable; hence, in many cases either each danger stage is represented by a unique color, or only the boundaries are shown by colored lines, as mentioned above. Generally, it is unnecessary to indicate Danger Stage Five, which signifies that inundation is occurring, so only danger stages one to four are shown. Further, although the proposed color regulations stipulate that both danger stages three and four should be red, in many cases, Danger Stage Three is painted yellow or orange.

When a river’s level is raised by torrential rainfall, the river manager visually monitors the dangerous-water-level signs to distinguish the danger stages and issue reports to each city, town, and village concerned.

**Roles of dangerous-water-level signs placed on rivers**

As part of efforts to improve the public’s understanding of dangerous-water-level warnings, in recent years, dangerous-water-level signs have been placed in locations where they can be seen by residents during their daily lives, such as while strolling by rivers. However, a survey of existing dangerous-water-level signs shows that people still do not understand what these signs signify. For example, as mentioned above, in many cases no additional notification is placed alongside water-level signs explaining the information shown and informing the public of the danger stages of the water levels. This means that if people only see the dangerous-water-level signs, sufficient information is not being communicated to them. Thus, it is clear that, despite the new measures, little has been done to help ordinary people understand the information. We believe that new innovations and techniques to communicate information are required to accurately convey this vital information to ordinary people.

**Widely publicizing dangerous-water-level information**

The Meteorological Agency website explains the relationship between the colors and danger stages indicated by dangerous-water-level signs, along with the level of danger represented by each danger stage. Further, water-level information for rivers directly managed by the national government can be checked in real time through the “River Disaster Prevention Information” website; the websites of river offices provide information linked to the River Disaster Prevention Information website. Moreover, for water-level
information concerning rivers managed by prefectures, the Foundation of River & Basin

Integrated Communications has prepared a website linked to general disaster-prevention information websites. Many of these websites can be accessed using smartphones or other portable information terminals, so wherever there is an Internet environment, it is possible to obtain water-level information for certain rivers. Furthermore, it is also possible to obtain water-level information through terrestrial digital broadcasts by NHK simply by using the data button, meaning even people who have difficulty using information terminals can obtain such information from their TVs.

As the season of frequent torrential rainfall nears, news reports, etc., often refer to this information to widely publicize that people can easily obtain river-level information. In addition, river managers publish brochures and/or posters stating that river level information is being provided, while social network services, etc., widely report the existence of river-related disaster-prevention websites. It is also now widely known that river level information is provided at a variety of events held at river facilities, etc.

For the above reasons, it can be concluded that means of providing ordinary people with river level information now exists, and that people have been well informed of their existence. However, it is clear that when torrential rainfall occurs, few people obtain river level information from the River Disaster Prevention website and other websites or through their TV sets, and many people are still unaware that they can obtain such information from the Internet or through their TV sets. A possible reason for this is that they do not require such information at the time it is publicized, so they take whatever measures they feel best without actually accessing the websites. Under these circumstances, obtaining such information does not become a firmly established custom, and it is predicted that when there is torrential rainfall, people will not even recall the method of obtaining river level information.

Thus, although it is widely known that water-level information is provided by sources such as the River Disastor Information website, innovative means of inducing users to take an interest in and aggressively access this information have still not been introduced, so it can be concluded that these measures do not function effectively.

**Analysis of dangerous-water-level information for rivers**

River level information is, from the perspective of ordinary people, unnecessary for their daily lives. While they realize that it is important information when torrential rainfall occurs, and that they must acquire it as advance knowledge, people generally do not remain habitually vigilant. As torrential rainfall and other natural disasters are extraordinary events, it is difficult for people to realize that they could personally be impacted by them, and during normal times they treat it as inapplicable information, which presumably prevents them from storing it.

Considering the fact that basic information such as the danger stages stipulated for existing water-level information are integrated nationwide, and that this information is already provided on websites or through public broadcasting, it is thought that revising this basic information is currently inappropriate.

Thus, according to these findings, instead of merely providing the basic information, it is also necessary to attract the attention of ordinary people to the communication method. By creating interest, it might be possible to teach the information to people as advance knowledge and encourage them to habitually obtain it.
Proposed river level information communication technique

If seeing dangerous-water-level signs while walking along a river arouses people’s interest, attracting them to information-providing sites, this information would penetrate more effectively. However, in order to avoid detracting from rivers’ scenic qualities, there are restrictions concerning the addition of new information to dangerous-water-level signs. Thus, it is assumed that if people can be taught to recall dangerous-water-level information when they see dangerous-water-level signs in daily life, such signs can function as interfaces.

Although it is necessary to devise a means of publicizing this information to all, it is considered to be effective to first choose a target population and gradually and exponentially publicize the information. Consequently, we decided to target elementary school children, who are a group that regularly visit river facilities as part of school events. It is also thought that with torrential rainfall now becoming more frequent, it would be useful to begin by raising consciousness of river level information among children. We believe that it is likely that children will pass such information on to their parents, and that the adults will possibly spread the information to other people.

Using stories and characters to provide information

We studied the use of stories and characters as a means of conveying river level information, which is generally difficult to present in an interesting way, and as easily understood and entertaining information. The most important aspect to convey is guidelines concerning the recommended actions that should be taken in response to each danger stage. Consequently, to make the categorizations and colors memorable and interesting, mascot characters were created representing the colors of each danger stage. Then, a story was written in which the characters act in ways appropriate for each danger stage when river levels rise, encouraging understanding of the actions recommended for each danger stage.

Developing an interest in and becoming familiar with characters or a story presumably motivates those receiving information to do so positively, so animal characters that are attractive to children were drawn. Figure 2 shows a sample picture book, the characters are shown in Figure 3, and Table 3 presents the story.
Hey, do you all know about the river, and the animals that live on the river?

A white polar bear, a yellow giraffe, an orange lion, and a monkey with a bright red face.

These four animals love all of you and want to keep you safe, so they escaped from the zoo to live on the river.

What? I didn’t know that. I hadn’t noticed it. Where on the river do they live? What do you mean by keeping us safe?

They often live around bridge piers or on the river dykes. Look carefully along the river and you will see white, yellow, orange, and red painted on bridge piers or on the dykes. Look! I see many, many painted bridge piers.
Right!! White places mean a polar bear. Yellow places mean a giraffe. Orange shows where the lion lives, and red places mean a red-faced monkey!! What are they doing there?

The white place is Danger Level One. The white polar bear lives here. "I am very good at swimming. When there is heavy rainfall, there is more water in the river, so the water rises up to Danger Level One, where I live. When this happens, I swim skillfully in the river, where I watch to make sure that there are no large logs flowing downstream and nobody is still playing along the river. I also notify the local flood brigades, who are on standby."

The yellow places show Danger Level Two. The yellow giraffe lives here. "My neck is really long, and it helps me see for a long way. When there is very heavy rainfall, I can see that the water is rising beyond Danger Level One, where the polar bear lives, to Danger Level Two, where I live. When this happens, this long neck that lets me see far away is very useful. That is because I can see all of my surroundings and I can give appropriate warnings. Also, when even more rain falls, raising the water almost to Danger Level Three, where the lion lives, I can immediately warn him."

The orange place is Danger Level Three. A lion with an orange mane lives here. "I am proud of my orange mane and my loud roar. When there is really heavy rainfall, the giraffe, who is on the lookout over a wider area, warns me that the water is going to reach Danger Level Three, where I live. After the water rises to my place, I desperately warn everybody with my loud voice. Roaaaar! Roaaaar! (meaning "everybody get ready to escape!!") Roooaaaar! Roooaaaar! ("once you are ready, get away!") Roaaar! Roaaar! ("warn your neighbors as you escape!!"). But if nobody pays attention to me despite my desperate attempts to warn you, my voice will become drowned out by the sound of the falling rain, and you will not hear my warnings anymore."

The red place is Danger Level Four. The red-faced monkey lives here. "I'm an old boss monkey. I live with polar bear, giraffe, and lion on the indications that inform you of dangerous water levels on the river. When there is really, really heavy rainfall, the water rises to Danger Level Four, where I live. I suppose that lion has told you that before the water reaches my place, he uses his loud voice to tell you all to get ready to escape, hasn't he? After lion has finished warning all of you, he calls on me. You wonder why he does that, don't you?"

"When the water level has reached me, the water will probably overflow at places where the dyke is low. It takes me a long time to escape because I am old; so, lion always calls out to me, telling me to escape with him just before the water reaches me. I am saved because he always calls me early. He teaches me that it is important to escape quickly."

Is that so? I didn’t know any of that. I didn’t know that those indications along the river show the degree of danger when heavy rain falls, similar to a yardstick for escaping. Or that when there is heavy rainfall, they warn us to escape in order to save our lives. I didn’t know anything about that. I am sorry I did not notice it before.

Thank you all for caring about us.

From now, on, whenever it seems to be raining endlessly, I will remember you all. I will be very careful to listen for lion’s warning! I will prepare to escape once the water reaches the lion. I absolutely promise.

**Evaluation of the sample picture book and future study**

We performed an interview survey concerning the picture book with leaders of a residents’ group that conducts various activities along the Onga River, which flows through Nogata City, Fukuoka Prefecture.
Their evaluation concluded that transmitting information through a story stimulates feelings of familiarity and interest far more effectively than conventional methods of providing information; however, in regard to the content of the story, they highlighted that children in the lower grades might confuse the characters of the animals designated for each danger level with the level of danger represented by the animals in real life. This information was obtained from a group leader who was a former principal of an elementary school, so his opinion is valuable, and consequently we believe it is necessary to reconstruct the content of the story to address this issue.

Nevertheless, the group did generously praise the method of using stories to communicate water-level information. We believe that devising innovative communication methods can support the wide dissemination of such information. We will consult with river offices and residents’ groups and examine the content of the story in order to prepare a new sample picture book; then, we will test it with elementary school children to verify whether this innovative communication method can effectively publicize information that generally does not interest people.

Issues of Devices and Applications for Supporting Walking in Older People
- Focus on the Information Provision

Ryoichi Tamura, Kyushu University, Fukuoka, Japan, tamura@design.kyushu-u.ac.jp
Yohei Ariyoshi, Nagasaki Domestic Relations Court, Nagasaki, Japan, orangeballsboys@gmail.com

Abstract
Japan has become a super-aging society, with the number of older people (over the age of 65) at a historical high both in absolute numbers (33 million) and as a proportion of the total population (26.0%), where one in four individuals is elderly (Director General for Policy on the Aging Society, Japan Cabinet Office. 2015). As part of the aging process in people, a certain degree of deterioration in physical performance is inevitable. However, it is essential to minimize the degree of functional decline and maintain the ability to engage in daily activities without hindrance, and these are urgent topics in the era of the super-aging society (Kawakami, et al., 2004). For older people, exercise is essential to maintaining good health. According to a Ministry of Education, Culture, Sports, Science and Technology survey (Ministry of Education, Culture, Sports, Science and Technology. 2013), the majority of people over the age of 60 replied “walking” in response to questions about the kinds of exercise they had performed in the previous twelve months, and the kinds of exercise that they would like to perform in future. Moreover, walking is known to be associated with positive psychological improvements, such as a subjective sense of wellbeing, life satisfaction, and a sense of purpose in life, as well as improvements in physical and mental function, such as arm/leg muscle strength and standing balance. In this study, we focus on information about functions for assisting walking, comparing and contrasting the information provided by existing products that support walking with the goal of clarifying issues from an information-provision viewpoint. We conducted interviews with eight older people who go for walks on a daily basis, asking about their thoughts before, during, and after walking. From 110 total comments, we obtained 30 comments relating to the action of walking. Furthermore, we investigated the functions of 11 devices and 20 applications that support walking, and from 24 functions, we focused on 20 functions relating to the action of walking. By comparing and contrasting the twin perspectives of “information items” and “information content” with visualization levels identified in the field of management, we clarified issues relating to devices and applications for supporting walking among older users, from the viewpoint of information provision.

Keywords: Walking, Older people, Healthcare, Device, Application, Information provision
and a sense of purpose in life, as well as improvements to physical and mental functioning, such as arm and leg muscle strength and standing balance (Murata, et al., 2009).

A wide range of products to assist walking have come onto the market in recent years, but relatively few have been targeted at older people. Accordingly, in this study we focus on information (Jouhou, n.d.) about the functions for assisting walking, comparing and contrasting the information provided for existing products that support walking with the goal of clarifying issues from an information-provision viewpoint.

1. **Viewpoint of this study**

In this study, we take “walking” to be an activity directed at a certain goal or ideal, focusing on the number of steps taken or the distance walked, for example. Thus, we carried out the research described below with reference to the visualization levels that have been identified in previous work in the management field (Miyazaki, et al., 2006).

These visualization levels are as follows (Figure 1). (1) Making the current situation visible, (2) making their goal visible, (3) the gap (or deviation) between the goal and the current situation, (4) establishing a specific action to reach the goal, and (5) making the progress toward the goal in the process of the activity visible. These levels are abbreviated below as (1) “current state,” (2) “goal,” (3) “gap,” (4) “action” and (5) “progress.”

![Figure 1: Visualization levels](image)

2. **Information required by older people**

2.1 **Investigation**

Between October 2015 and January 2016, we conducted interviews with eight older people (Table 1) who go for walks on a daily basis, asking about their thoughts before, during and after walking.

2.2 Results

From these interviews, we obtained a total of 110 comments from the eight survey participants (Table 2). We classified comments into three categories according to content: 1) 30 comments relating to the action of walking, such as “I wonder how far I’ve walked so far (A17),” “I’m very thirsty (C7),” “I walked well today, as usual (D11),” “I should weigh myself and check the result of today’s walking (F17)” and “When I’s cold, my heart and lungs get tired (H8)” ; 2) 35 comments relating to the circumstances surrounding the walk, such as “Tomorrow I might walk when it’s a bit cooler (B13)” ; and 3) 45 comments not directly related to walking, such as “I’m all sweaty. I’m going to have a shower (E15)” and “Let’s buy breakfast and go home (G5).”

Accordingly, we decided to focus our subsequent considerations on the 30 comments related to the action of walking, as comments in alignment with the viewpoint of the study: walking as “an action directed at a certain goal or ideal.”

2.3 Required information items and information content

Within the 30 comments selected, we first examine which information items were required by the survey participants. Considering comment A17 (“I wonder how far I’ve walked so far”),
for example, three possible information items are “number of steps,” “walking distance,” and “walking time.” We considered each of the other 29 comments using the same approach. Doing this allowed us to extract seven types of information item, which we broadly divided into items related to walking and items related to the body (the left-hand side of Table 3). Next, we examined the information content required by the survey participants. Considering the three information items (number of steps, walking distance and walking time) listed above for comment A17 (“I wonder how far I’ve walked so far”), for example, the information content is likely to be “the situation up until that point in time.” We considered each of the other 29 comments using the same approach. We were able to extract six types of information content (the right-hand side of Table 3).

3. Information provided by existing products

3.1 Investigation

Products that support walking can be classified into two types: dedicated devices and smartphone apps. The sample products for this investigation were chosen by conducting a web search with the keywords “walking & device” and “walking & app” and selecting the 11 devices listed in Table 4 and the 20 apps listed in Table 5. We then investigated the functions of these devices and applications.

3.2. Results

As a result of this investigation, we were able to identify 22 device functions and 23 app functions. Grouping similar functions, we classified functions into 24 different categories, including functions that measure how many steps have been taken so far (step counters) and functions that measure how far one has walked (distance trackers). See Table 6 for these. Looking at these results, it appears that functions can be classified into (A) functions relating to the action of walking (20 functions, such as step counters) and (B) functions relating to the circumstances surrounding walking (4 functions, such as setting up courses).

Accordingly, we decided to focus on the 20 functions in the (A) category (functions relating to the action of walking), which agrees with the viewpoint of this study as outlined earlier, namely, walking as “an activity directed at a certain goal or ideal.”

Table 6: 24 functions

3.3. Available information items and information content

We started by considering what information items are provided by each of these functions. For functions such as “count steps,” “set step goal,” “manage step goals” and “notify of milestones in step count,” for example, we regard the information item as “number of steps.” We considered each of the other 16 functions using the same approach. As a result, we were able to extract 5 types of information items, broadly divided into items related to walking and items related to the body (the left-hand side of Table 7).

Next, we examined the information content provided by each function. Considering the “number of steps” item for the “count steps” function, for example, we regard the information content to be “the situation up until this point in time.” We considered each of the other 19 functions using the same approach. We were able to extract 5 types of information content (the right hand side of Table 7).

4. Analysis based on visualization levels

4.1 Connection between the information required by elderly users and visualization levels
From the results of section 2, we organized the connections between information items and information content by assigning them to visualization levels. The results are summarized in Table 8. We found that under the category of information items related to walking, the “number of steps” and “distance walked” items correspond to all levels other than (4) “action,” whereas “walking time” only corresponds to (1) “current state.” Similarly, under the category of information items related to the body, “pulse rate” corresponds to all five levels and “calories burned” corresponds to all levels other than (5) “progress,” whereas “blood pressure” and “hydration” only correspond to level (1) “current state.” Thus, we found that the visualization levels for the information required by older users varies considerably depending on the information item.

4.2 Connection between the information provided by existing products and visualization levels

Based on the results of section 3, we organized the connections between information items and information content by assigning them to visualization levels.

The results are summarized in Table 9. We found that under the category of information items related to walking, the “number of steps,” “distance walked” and “walking time” items correspond to all levels other than (4) “action.” Similarly, under the category of information items related to the body, “calories burned” corresponds to all five levels and “pulse rate” corresponds to all levels other than (5) “progress.” Thus, we found apparent differences in the visualization levels for the information provided by existing products depending on the information item, but we also found that information for most visualization levels is already available.

4.3. Discrepancies between the information required by older users and the information provided by existing products

We compared and contrasted the information required by older users and the information provided by existing products on the basis of visualization level (Table 10).

</tr>
</tbody>
</table>

Under the category of information items related to walking, for the “number of steps” and “distance walked” items we found that functions satisfying the visualization levels for information required are already available. In contrast, for walking time the functions available have information visualization levels that exceed the needs of those we interviewed, and so instructions on how to use these functions may be needed.

Under the category of information items related to the body, we found that for the “calories burned” item, the functions already available have information visualization levels beyond the needs of our interviewees. In contrast, for the “heart rate,” “blood pressure” and “hydration”
items, functions providing the information visualization levels required by older users are not yet available and such functions should be added. In particular, the functions for “blood pressure” and “hydration” do not meet the very basic visualization level of (1) current state, and we believe that such functions should be added as a matter of urgency.

5. Conclusion

This study focused on walking by older people, using the twin perspectives of “information items” and “information content” to organize the information required by older people and the information provided by existing products. By comparing and contrasting these perspectives with visualization levels, we have been able to clarify issues relating to products for supporting walking by older people from the viewpoint of information provision. Future challenges may include the need to increase the number of survey participants and conduct additional surveys in different seasons. This work was supported by JSPS KAKENHI Grant Number JP15H01761.

References

In this study, we define information as “something that notifies the content or state of a certain thing”. Moreover, in this manuscript we describe a “certain thing” as an “information item” and the “content or state” as the “information content”.

Author Biography

Ryoichi Tamura
Ryoichi Tamura is an Associate Professor at the Department of Design Strategy, Faculty of Design, Kyushu University, Japan. He is also a member of the board of directors at JSSD since 2006. He holds an ME and a PhD in Engineering (Chiba University, Japan). Recently, his research scope has expanded not only product design but also service design. He has several publications in international conferences such as IASDR, KEER, ICED, ISIDC and ICServ. Now he is working on a project entitled “Study of service design to improve the quality of life of healthy elderly utilizing their daily life information”, which is supported by Japan Society for the Promotion of Science.

Yohei Ariyoshi
Yohei Ariyoshi studied service design at the School of Design, Kyushu University, and studied the needs and desirable services for older people in the graduation study on the theme of older people and walking. After graduation in 2016, he became a national civil servant, was employed as a court secretary in the accounts section in Nagasaki Domestic Relations Court, and is working to support the administration of the trials.
Dada posters in a post--colony

Niina Turtola, University of Lapland, Finland, nturtola@ulapland.fi

Abstract

Graphic design is often seen in the commercial context and is discussed through topics linked to software and technology. When we look around us we can realise that billboards, banners, posters and most of the print that surround us in the public space are delivering messages of marketing, corporations, consumerism and other commercially inclined narratives. This, however, is not the only way to comprehend the practice of a graphic designer. Graphic design can take a socio-pedagogical and historical role and distribute alternative messages in the society which are not linked to money and consumption, unless education, reading and studying are considered consumption of sorts.

It is obvious that graphic design is a powerful tool that shapes our understanding of reality. This happens through being exposed to the work. Posters are claimed to mirror societies by many theorists and most visual communication is mediated by a graphic designer. Thus, Bonsiepe stated already in 2005 in his speech Design and Democracy that there is an absence of questioning activities linked to design production. It is yet a relevant theme that research needs to approach; also in a post-colony where the printed poster is ubiquitous. A simple sheet of printed paper. A very simple but extremely complex and powerful. There lies an investigation that this paper will start. The outcome of this paper to share knowledge within the researchers about creating new meaningful pathways in understanding globally important practice of graphic design. Art and design are universally important.

Keywords: graphic design, printed poster, socio-pedagogical, post-colony, history

The purpose of the paper is to show through theoretical references, case study and discussion that graphic designers have the possibility to incorporate socio-pedagogical and historical motives, as well as questioning activities, in the generally commercial and client oriented nature of graphic design. As an outcome, I want to create a reader to see that graphic design does not only prevail in Finland, the rest of the Europe, United States but is ubiquitous. It functions in the same commercial manner in the public urban spaces in the post-colonial South Africa, Namibia as in the ‘West’. Researchers need to investigate further, not how things look or opinions about them, but how ‘things’ are practiced, in which context, and what is represented: To define what visual reality looks like. Definitions of graphic design are redefined continuously in each interaction between the printed sheet and the viewer, be it active or passive relationship.

I will start by defining the terminology. After this I will explain my research position. Thereafter I will introduce literature to define graphic design and link this to its socio-pedagogical and historical framework. I will show questioning activities. As a theoretical framework, I use writings of Bonsiepe, Potter, Müller-Brockmann, Van Toorn, Sontag, to name a few. It is necessary to introduce also writings from the South-Africa and to bring the
local understanding closer to the reader.

**Terminology: Case study, artistic research, DADA, poster and post--colony**

I conducted a *case study* from artistic research perspective. Borgdorff defines *artistic researcher* as a study where art practice is central to the research itself and that the creative process forms pathways to insights and understanding (Borgdoff, 2012, p.145-146). I position myself as an artistic researcher that conducted a case study in a post-colony. My researcher position is that of a permanent inhabitant in Windhoek, Namibia, for approximately a decade. I have been active in the society as artist, educator, performer, designer and as an artistic researcher.

*Case study* is defined by Karlsson (2016, p.3) as a single instance and a sample of one investigation of a phenomenon from a real-life context. She indicates that researchers use case study to identify what is common about the case study to explain the reader how or why something happened.

*DADA* refers to information retrieved from Museum of Modern Art, New York, website: [http://www.moma.org/learn/moma_learning/themes/dada](http://www.moma.org/learn/moma_learning/themes/dada). “For us, art is not an end in itself,” wrote Hugo Ball, “but it is an opportunity for the true perception and criticism of the times we live in.” The case study is ‘dada’ in nature. It was created not for the posters themselves but towards challenging seeing and perception about the posters and design in the society. DADA is a mirror of the society through the case study, that shows the power of design.

With *poster* I refer to Müller-Brockmann (1971/2004, p. 22) who writes: “Posters are barometers of social, economic, political and cultural events, as well as mirrors of our everyday lives.” Sontag (1970,4) refers to Hutchinson’s definition of posters dictated by the demands of a service, message, or products and Sontag, herself defines poster artist as “works for money and tries to please the client”. This definition supports my view on how graphic design is linked to corporations and commercial entities directly.

The term *postcolonial* is difficult to define in a simple manner. The term has both historical and ideological significance. Postcolonialism is a critical theory focusing on colonial experience from the colonised society’s point view, semantically post colonialism means something that has a concern only with the national culture after the departure of imperial power. This case study brings DADA to people who might feel ambiguous towards it due to historical reasons. If I spoke about DADA as a white Caucasian female researcher, the words would be linked to me, not to the information, potentially. Streets are public spaces that offer individuals the choice to read, or not to read.

**Literature review**

Bonsiepe (2006) discusses the alarming absence of questioning activities in the design discourse. He indicates that academia still offers a space for this type of endeavour, whereas it seems otherwise slightly problematic to start a dialogue in the cultural context. Bonsiepe also
points out that designers aspire towards two minutes of fame and mentions design coffee table books that exempt readers from intellectual efforts. Design with democracy is not enjoy popularity as discussion. Whereas the word “fashion designer” is rather sexy (my word choice, not that of Bonsiepe). Bonsiepe says that design is distanced from intelligent problem solving and moving towards quick and obsolete boutiqueization of the world universally. I agree and I am starting a dialogue through the posters.

50th anniversary of the Warsaw International Poster Biennale, in June 2016, write on their website; “The Poster Remediated will explore how the conventional poster is undergoing rapid transformation in an age of ubiquitous digital screens and social media. It will show that the internet has not – as some commentators have suggested – killing off the poster. But the medium is being changed by digital technology”. With this citation, I see emphasis on what is conventionally being discusses: technology, and technical aspects. It seems secondary to discuss the art of posters and the content. Why are posters being made and with which purposes? Is graphic design only submissive to a third party? The thinking mind behind the posters as art? To answer a brief? This is a text book example discourse stuck in technology. Also, Crowley (2016) discusses – digital poster in the same context of Warsaw Biennale. The focus should be on ‘What?’ rather ‘How?’ and ‘Why?’.

Van Toorn states (Poynor, 2008,79): “The problem of design today is that it is more fascinated by the visual, as a realistic imitation or decoration, and not by the image as a subjective narrative and interpretive element.” A designer cannot adopt a position of a neutral intermediary for Van Toorn (2015, 22). He (2010, 46-47) pleas “not to lose contact with social reality, to maintain an open eye and a critical mind for the conditions in which we produce, and for the effect it has on the recipients. He advises us to strive for dissident behavior and to accept more dissonance in the process. Van Toorn continues “a language use that liberates us from the forms of domination that design and its concepts still exercise today”. Van Toorn, in Critical Practice, (2008, 79) offers alternative ways of thinking to be embedded into the everyday commercial practice of design. The DADA posters show the potential and news ways of becoming an active citizen. Graphic design is guerilla advertising, where anyone and everyone is manipulated. I will come to this later.

Economou (2012, 39) writes that “the visual media encourages and reproduces a culture where ambitions of glamour, sexualisation, and material wealth provide social status and recognition over “traditionally” valued concepts such as education, family values, work ethic, and civic duty”. Sounds like the ‘West’, does it not? It is. Van Toorn (2010, 46) writes about ‘reality’ and that “presentation is missing an authentic point of view and a form relating the unearthed material to our experiences in reality”. Therefore, poster mediated our new potential realities as well.

South African designer Mac Garry (2008, p. 9) claims that graphic designers can do what they want. Spiekermann (2006, 165) says on the other hand that artists express themselves, not graphic designers. Mac Garry (2008) seems contradicting himself in his writing as he publishes a text book about graphic design, yet the focus, in my opinion in personal opinions rather than theoretical. Hence, he (2008) also states that are no rules but then shows the basic
universal rules of graphic design that are universally identified. Reader must be confused. We need to perform criticism to what we read and what we believe. If the establishment is vague, how can we? Maybe it is challenge to simply learn to question.

MacAvery Kane writes: “Graphic design serves as a filter through which much of our communication is disseminated. Graphic designers find themselves in the unique position of being gatekeepers of information as well as providing a mirror that reflects contemporary culture.” Designers are juxtaposed; how can they earn a living and offer positive alternatives all at once.

Müller-Brockmann (2004, 12) says posters mirror everyday lives in the society. Repetitive mirror becomes reality through the repetition. Müller-Brockmann (2004, 12) refers to Bense who purposes that design exists to glorify and to manipulate behaviour. Posters for Bense solve problems, but also confront us with new ones. Kepes (1995, 221) writes that: “Posters on the streets — could disseminate socially useful messages, and they could train the eye, and thus the mind, with the necessary discipline of seeing beyond the surface of visible things, to recognize values necessary for an integrated life.” (1944, 221) DADA poster aim at manipulating to change behaviour towards reading, art and design.

I have presented literature and thinking that has influenced the case study. I placed a mirror or posters to the society. Poster carry knowledge and the work has been distanced from the conventional poster designs.
Case study: DADA posters in a post-colony

Figure 1. The first reader arrived on the 6.10.2016 as I was finished posting the work. The reader was created. I do not witness people reading ‘conventional’ posters; I have no proof of that.

Through this case study I want to show the alternative futures of design. The purpose is to share information and offer a possibility for an individual to learn and to see alternative. I started by sending an email to approximately 150 people; artists, designers, educators etc. in Windhoek, Namibia on the October 3, 2016.

“STREETS ARE BECOMING A LIVING LIBRARY!

We have distributed D,A,D, and A (DADA) posters in Windhoek to celebrate the 100 years of DADA art movement and in celebration of art and design education and practice. This DADA 'streets are libraries' campaign celebrates the potential of graphic design through a printed poster in conveying socially beneficial narratives and messages!

What is DADA? Who knows DADA? Who cares DADA? Now people can decide for themselves, they can make the choice of learning or not learning. We don’t know unless
we learn. Streets are libraries!

Graphic design can approach socio-pedagogical issues and it does not only have to be concerned about corporate and commercial affiliations. Most of graphic design is doing this. There are alternative methods the discipline can do to create a larger discourse in the society about art, design and education and society as whole. We are aiming to create awareness about design and art visions, that are not linked to corporations nor consumerism. Except if knowledge creation, reading and learning is considered consuming.

We wish that you will contribute to the awareness building of art, design and education by printing any of the attached posters and posting them anywhere in your neighbourhood. Distribute as many as you like!!

I write in an intuitive basis. I think for a long time and then act. I think that we globally share a common history of graphic design and art. We must write news histories. In South Africa, students, as a protest towards the local current unhappiness towards systems, I assume, burned art works and demanded statues to be taken down (Daily Maverick, n.d) in August 2016. I do not support violence, nor art burning. It reminds me of the history of burning books. Art history is universal heritage. Decolonising is a new buzz word, but decolonising exactly what and how?

I worked four years as a government lecturer of graphic design, where else do I start than history? I took design to where it belongs, streets. I created ephemeral libraries. I was an advertising agency, imaginary, but real. “What Would Hugo Ball or Marcel Duchamp say?”: I thought that art history is as important to an art student in Namibia as in Finland.

I designed 21 DADA posters based on text found online. I did not waste time in designing; I did it in my mind before. I copied texts, printed and made approximately 300 copies to communicate socio-pedagogical and historical meanings to be viewed by the everyday people in the City of Windhoek, the capital of Namibia. The campaign forced viewers to view the work as it looked different (see figures 1., 2., 3.). I posted installation to five different sites and distributed individual posters in the city everywhere. All the different posters and few reprints of reprinted authentic DADA posters were distributed in five locations. Nothing was for sale and the project was self-funded. It should have been sponsored by a company. The experimental campaign carries similar pioneering attempts as the Dadaists undertook to intervene and question long-held assumptions of what art and design should be.
Figure 2. A local taxi stopped and the passenger to said the words DADA.
Figure 3. “Drop the Shadow, just drop it!” is my advice as a lecturer of graphic design to beginners.

Why do the streets posters look like Photoshopping exercises (Figure 3.), but not good graphic design? Is it cultural design and repetition of the convention, started by anyone who started to Photoshop posters? The word on the streets is that the person is making money who designs these posters, but is not educated. Does it matter? A clever business man, self-expressionist or an extension of the client’s arm? These are questions that research needs to approach.

**Discussion**

The case study followed Bonsiepe’s (2006) inquiry to ask questions through actions and Van Toorn’s philosophy of design to embed alternative views. I question the surrounding posters and therefore the poster production. Potter (2002, 53) discusses client brief and its falsity which leads to my informed opinion that many street posters are ‘surface of the face of things’ (Potter, 2002, 53). Posters can be visual pollution. Sontag used (1970, 4) words ugly, banal and decadence to describe posters. Self-expression, corporate clients and briefs, or maybe socio-pedagogically and historically oriented way to develop artistic research? I chose the latter in this case study to write about. “As the extended arm of the client, it (poster) should
lead viewers to the product and appeal to them in such way that the message finds its way into their unconscious mind” (Müller-Brockmann 1972/2011, 12). The DADA posters lead to potential reading.

William & Newton (2007) researched collective memory and how it is formed by a cumulative effect of media-generated images and events. They write that media delivers visual images that create a sense of what is normal and acceptable linked to our values, lifestyles and behaviours. Media, I think, hijacks the idea of reality. Graphic designers present it visually on a repetitive basis. William & Newton discuss that we think we select what we see, but in fact our non-conscious memories and predispositions guide us in seeing. Our intuitive cognitive processes, according to them, receive more information than we consciously note.

Guffey (2015, 287) writes: “there has been a mistaken idea that global graphic design is nothing more than the Westernization of design forms worldwide”. I am looking forward to interesting Namibian styles, that are not repetition of the internet of things. Hand-made posters might be the solution, but now computer, I know this from four of teaching experience. Ban Photoshop! “Guffey says that posters are a stubborn and resilient form and continue to develop in new ways entirely outside the West.” I have seen interesting hand-made typography in Namibia, but not poster design.

Conclusions

“What software do you use?” Most frequently vocalised words as I say: “I am a graphic designer”. Convention. Spiekermann (2006, 164) says that the only time people discuss design is when it does not work. For the same reason, we need to expand our work beyond it. In this paper, I have shown options how this can be done. The viewer has been fed new information. By repetition it becomes a norm. Viewer does not like nor dislike, conventional posters just are there, a wallpaper, like lukewarm water, in my opinion. Outi Nyytäjä, a Finnish dramaturg and actor passed away in 2017. I never forget a radio interview in 2009 as she said: “Water needs to be cold or hot, not lukewarm. That is a death sin”. I have no reference to that except my memories. We can influence collective memory by actions. The DADA posters in post-colony is a case study conducted by artistic researcher. I showed how designer can swim against the main stream aiming at creating socio-pedagogical and historical knowledge potential. I promised an investigation into the simple yet complex sheet of paper. The poster. Further questioning needs to happen through further research.

**Autobiography**

Niina Turtola

Niina Turtola is a candidate at the Culture-based service design doctoral programme at University of Lapland, Finland. She commutes between Namibia and Finland. She is a graphic designer by profession and she swims against the stream as it is what typographic artistic researcher must do, in her case. Turtola studies text and typographic language as material and as interpretation in the artistic process. She interprets, through typography, already printed texts in the society, and makes artistic design of them. In her research, the texts are always interpretation, therefore the design mirrors also the viewer through reaction.

Her thinking practice plays a more important role than actual designing, that is intuitive. The artistic process leading to an art work is fast as light, almost. She believes in thinking rather than creating pretty pictures and surfaces, that are too conventional. Turtola has created a method to create the unfamiliar following a theory of Viktor Shkolsky (1917). Her brave and self-initiated project is the subject of her doctoral research: productions of fictive Ministry of Truth and Typography. She wonders why so many graphic designers stick to corporate practices rather than explore their own artistic practices?
An Interdisciplinary Exploration of an Analog Tool to Elicit Socio-Cultural Narratives

Hemalatha Venkataraman, MFA Candidate, Design Research and Development, The Ohio State University, Columbus, USA, venkataraman.33@osu.edu

Abstract

Eliciting multiple stakeholder narratives is a critical factor when designing systems, services or products. This research explores how the use of an analog tool (the picture postcard) in the digital age can be used to elicit socio-cultural stories to support design for ‘social practice’. The process combines people and things by using a participatory design approach and material culture studies to design, explore and analyze the complex nature of interactions between social ideals and the artefact.

The study emphasizes ‘slow immersion and design’ by creating prolonged interactions that allow people to sit with someone else’s perspective while also introspecting about their own. In an age of echo-chambers, the research examines the impact of reducing the risk of fragmentation (where people assign themselves into homogenous groups leading to an amplification of pre-existing views (Sunstein, 2001)) on participants’ ability to generate and sustain a healthy exchange of honest, social narratives.

The research findings reveal a deep bonding between participants and a reduction of implicit biases that initiates a broader range of discussions within a given socio-cultural topic. The space for ‘elastic interaction’ (articulation of ideas without fear of judgment; when and how they want it to be expressed) allows honest thoughts to manifest. The findings also reveal that this process slowly allows for an empathetic acceptance of another’s perspectives.

The poster illustrates the research through these various approaches: the process of slow immersion and design research with a combination of postcard exchanges, one-on-one interviews and participatory design research activities to help elicit the stories for a socio-cultural co-design space.

Keywords: Slow Design, Methods and Tools, Interdisciplinary Design Research Methods, Community-Based Research, Participatory Design Research, Picture Postcard
Stories and narratives are invaluable. Every story a person relates is shaped by their own socio-cultural and economic background that forms a deep layer of experiential knowledge that can be tapped for designing better solutions and uncovering opportunities. Unearthing these stories moves toward a well-informed research process that allow for more empathetic design approaches, process, findings and solutions. The focus of this research study is to explore how these stories can be elicited for a particular setting or purpose: unearthing socio-cultural narratives, using an analog tool (the picture postcard) through interdisciplinary approaches.

Design Research as an industry is growing at an accelerating pace. More firms, companies and corporations are looking to use design research and thinking for the betterment of their institutions. However, placing the context of the times we are in now—an increasingly digital, fast-paced world-- there is significant pressure assigned to obtaining maximum results in the least amount of time possible. In a lot of instances, this approach is successful as new methods and ideas are developed to generate efficient systems that are put into practice. However, it has also created a culture of rushed processes and research methods in the industry that tend to follow a similar approach across a range of problem spaces—from market research to socio-cultural issues. This approach needs to be revisited as these are different kinds of problem spaces; with different needs, requirements and objectives, which means that these design spaces require different tenors to address them. It is thus necessary identify these goals for the problem space, and explore extending the time frame for the research so as to allow participants to immerse themselves fully in the subject matter and encourage an introspective environment (particularly for socio-cultural design research spaces).

It is important in areas of socio-cultural concern that the given problem space is explored, sifted and approached from multiple points of view, with a holistic sense of thinking to ensure a thorough process and obtain comprehensive results. The challenge for the researcher in this instance is to create a safe space for these stories to be honestly expressed, exchanged and recorded (given the nature of narratives to be sensitive and possibly personal). Focusing on smaller nuggets that aid this process like improving the nature of interactions between participants, and the researcher(s) to create a more trusting, reflective interpersonal and professional relationship could be pivotal to the kind of data that arises from the research (with the already established hypothesis that participants benefit from having more time to become comfortable with the subject matter as well as their co-participants and the researcher(s)).

With the approach of eliciting honest and otherwise tacit narratives from people as the primary aim, the following components of the research was to develop and explore methods and practices that are not pertinent only to mainstream design and design research but to embrace ideas from other disciplines that improve the means to elicit these stories, and analyze them (like art and material culture studies).

On the whole and in summary of the introduction, the larger idea of the study is to explore and challenge those aspects of research methods largely found in the industry today, particularly with regards to socio-cultural problem spaces by working on it over a longer span of time than usual (in the case of this research- a five month period), employing interdisciplinary methods for a holistic approach to problem-solving and looking for opportunities in the given design
LITERATURE REVIEW

Slow Design
One of larger ideas being addressed in this research, as a core exploratory factor, is with regards to ‘slow design through immersion’. Slow design is a relatively new concept in design research and design thinking in that it encompasses longer design research processes with more time for research, reflection and fine-tuning of ideas; the approach is ‘predicated on slowing the metabolism of people, resources and flows, which could provide a design paradigm that would engender positive behavioral change’. (Fuad-Luke, 2002) A longer time frame for the purposes of research has the potential to allow participants to develop a deeper bond with other people and allows for the research findings to come through in the best manner possible. The aspect of more time also allows a range of perspectives, working methods and ideas to intersect. It is in this space that art, design and other disciplines (material culture studies, in this case) intersect in working towards projects that focus on social innovation. This space has been termed ‘social practice’ for the purposes of this research.

Eliciting Stories through Decisive Dialogues
It is imperative that a social operating mechanism such as a community or a city, with its different stakeholders, has important conversations about its visions, shortcomings, mission and culture in order to define problem spaces and design solutions for them. Given the socio-cultural, political and economic extremes that persist, there is often a gap in the understanding and working of one stakeholder group of the community not addressing the other, or even adversely affecting the other. The first step towards social practice, in my opinion would be to work towards a cohesive, social goal—and this can potentially happen through “decisive dialogues” between the different stakeholder groups. Decisive dialogues are crucial conversations that steer towards exchange of ideas, reflection and open discussions. ‘Decisive dialogues must have four components: “First, they must involve a sincere search for answers. Second, they must tolerate unpleasant truths. Third, they must invite a full range of views, spontaneously offered. And fourth, they must point the way to a course of action”.’ (Charan, 2006) This research focuses on tapping into decisive dialogues as a means to elicit honest narratives from participants, in the process of research conversations and later in focus-groups.

Approach: Co-Creative Design
When designing for and with people or social situations, it is important to ensure that the researcher doesn’t assume what it is that the people need, or what the social architecture requires for a solution. Solutions that arise from only the researcher’s comprehension and analysis of a given situation can be limiting in its perspectives and scope; it may contain assumptive stances that may prove to be harmful to the research itself. Thus, the primary step involved in a research that explores socio-cultural design spaces and community-based research is to call for a collaborative mindset with the people involved in the research. This entails moving from seeing them as being just ‘participants’ to ‘co-designers’.

‘Co-creative design’ as a mindset has been adopted in the research in order to ‘work with
people’, to consider them as the experts of their own experiences in order to explore problem spaces as co-designers. Stories are extremely useful in co-creative design as they are engaging and they evoke imagination and empathy that aid the process of designing better solutions. (As a combination of true and imagined natures of story-types, stories (and story-telling) are a very effective way to trigger ideas in a given design space, which is of applicable use in the case of research in socio-cultural problem spaces).

Figure 1: Levels of Knowledge (Sanders and Stappers, 2012)

Figure 1 illustrates the levels of knowledge possessed by people and the different methods through which these stories can be elicited. ‘Knowledge’ here refers to thoughts and ideas that one has experienced and has stored in their memory. There are four different levels of knowledge:

Explicit knowledge can be stated in words, and is relatively easy to share with others.

Observable knowledge refers to thoughts and ideas that can be obtained by watching how other people behave.

Tacit knowledge refers to things we know but are not able to verbally communicate to others.

Latent knowledge refers to thoughts and ideas that we haven’t experienced yet, but on which we can form an opinion based on past experiences. (Sanders and Stappers, 2012)

Some levels of knowledge are easier to access then others. Explicit and observable narratives are obtained through methods like interviews and observation exercises. However, the deeper levels of knowledge, namely tacit and latent, are much harder to unearth. These levels of knowledge are generally triggered during co-creative design workshops using a variety of techniques. This research is a combination of participatory design methods that explores how stories can be elicited at each of these levels, particularly tacit and latent narratives.

The Tool: The Postcard Exchange

Tools are extremely important in design research: through the planning, research process, analysis and findings, as well as in the final data delivery. In usual cases, the approach to
design research and designing something tangible (like a product) or intangible (like a system) is to start with the story, to look into behavior patterns, consumption, rituals etc. However, embracing interdisciplinary approaches calls for looking at the same problem space through a fresh perspective. The discipline that largely intersects this research (by virtue of proposing the use of a physical tool in a digital age) is material culture studies, where emphasis is laid on the object, its story and the complex nature of interactions between social ideals and the artefact. ‘Alternatively, material culture studies may take the human subject or the social as their starting point: the manner in which people think through themselves, and their lives and identities through the medium of different kind of things’ (Tilley, C. Y., Keanne, W., Kuechler, S., Rowlands, M., & Spyer, P., 2006). This allows for a new way of thinking about the design space.

This research in its process reached a question of how, and which physical tool suits to evoke honest responses from people. The chosen artefact for the purposes of the nature of exchange is the picture postcard which incorporates visual dialogue with its front side and space for written introspection and communication on the back. The postcard, with its minimal space, pushes the participants to refine their thoughts before they write, and also helps them to sit with their partner’s responses for a while before writing back instead of immediately responding, as in the case of face-to-face interactions.

**RESEARCH APPROACH**

The research, which spanned over a period of 5 months, had two parallel phases to it to understand how the picture postcard can be useful as a tool to elicit stories. The first phase was engaging in dialogue through actual postcards. Each participant in the research was paired with someone else from the same city (Columbus, USA) but from different socio-economic and cultural backgrounds so as to create a setting that allowed them the potential to explore perspectives different from their own. The topic being investigated was about ‘home and community’. Assigned co-participants exchanged postcards as their sole means of communication to talk about the topic during the research period, with the researcher being a part of the conversation by virtue of remote observations (for participants send a photograph of their cards to the researcher for documentation purposes). Emphasis was laid on setting this up as a safe space where the participants could decide what they say, how they say it, and when. They could choose to use their real names or remain anonymous. This kind of freedom allowed them the space to decide how much of themselves they wanted to reveal. This flexible space for the movement of the participants to exchange their narratives has been termed as ‘elastic interaction’ for the purposes of this research.

The postcards themselves were well-designed and illustrated with a mix of blank, mass-produced and artist-rendered postcards (by the researcher), of various sizes. Participants could pick and choose the cards they most resonated with to write on and send out to their partner. They were also given a set of ‘trigger questions’ for reflection that they could use should they feel like they’re hitting a roadblock in the conversations. Participants were handed over their postcard packets personally by the researcher, after the first interview, to help prepare them for the study.

The second, parallel phase to this analog means of communication involved the use of electronic mails with similar parameters to the postcard exchange in order to compare-and-contrast with
the postcard correspondences, except this method had worldwide participants. The participants of that parallel research phase sent images (also offered to them) and unencumbered mails (in length) to one another in the place of postcard exchanges.

The study also comprised of three one-on-one meetings between the researcher and every participant in the study—a preparatory meeting (with a participatory design activity to prime the participants about the subject matter), a mid-point meeting to track progress and thoughts, as well as an exit interview. The objective of these meeting is to encourage improved interactions between the participants and the researcher, and between the participants themselves since the final, optional interview brought both the participants and the researcher together to meet one another. All these interviews were well-documented through audio-video recordings as well as photographs. Also, each of these postcard dialogues were tracked and maintained on record by the researcher throughout the entire period of the study.

DISCUSSION

There has been a good amount of data that has been collected in the research process: the content on the postcards themselves, the participatory design activity data and transcripts from the three one-on-one interviews. These narratives and different facets of stories of people are observed, analyzed and studied through qualitative analysis in Grounded Theory.

The multiple interviews helped to develop interpersonal and professional networks and relationships between the participants themselves, as well as the researcher which could play a key role in a socio-cultural problem space. One of the other key insights of the study is that the postcard exchange can be used as a ‘priming method’ in a larger study in order to prepare participants before they attend participatory workshops and other kinds of social convening. The hypothesis is that a thorough priming of the participants about the subject matter and their own reflections on the same allows for introverted and even socially anxious people to be more confident about their ideas, especially if there is one other person in the room that they know and trust (their partner).

CONCLUSION

The research currently stands at the completion of the overall data collection with the project having come to an end and the exit interviews with the participants in place. The conclusions at this point in the research are largely positive. Some of the initial findings are as follows:

- 86% of the participants (out of the sample size of 20 pairs of participants) would like to meet their partners at the end of this research; no one has yet said they don’t want to meet their partners.
- 69% of the participants have expressed that they were more honest with their narratives in their postcard exchanges.
- 86% of the participants found themselves in increased introspection and reflection regarding the topic thus far in the research.
- 58% of the participants expressed good bonding, connection and relationship with their partners even before they met.
• 65% of the participants have said that their perspectives have been broadened in their conversations with their partners.

It appears that the research process has provided a safe space for open dialogue and conversation that invited people to interact with their counterparts with more vulnerability (without feeling threatened at the same time), by exchanging postcards with one another, so far in the study. In an industry where the bigger demand is for immediate results and findings, this research has the potential to address larger concerns and organizations like the healthcare industry or the work of NGO’s who have a cultural and social focus that could benefit from prolonged studies.

These primary results have been positive and as the third and final exit interviews come to an end, it appears to have better results than its email counterpart phase, largely owing to the tactility of the medium of communication. The insights from this research are to be presented to experts who have previously used postcards in their research in some manner or form from several disciplines like art, design, anthropology, material culture etc., to obtain their critique on the working methods of the research and its further applications. There is a vast amount of data collection in this research process that is of good use for socio-cultural problem spaces, and it will be a good way to go in for community-based research, social practice and innovation.

Hemalatha Venkataraman

Hemalatha Venkataraman is an architect who has completed her Bachelors in Architecture in India. As a qualified architect and also an artist by vocation, her research interests and work lie in exploring interdisciplinary approaches (the author has also completed a Graduate Interdisciplinary Specialization in ‘Analysis of Material Culture’) with a participatory design mindset, and designing for the larger social good and the community. Her cultural background and landscape allows for a fresh perspective in the research setting, as an international student in America. Alongside her Masters thesis, she is also pursuing a separate research which explores arts-based research in community-activism. She is currently a third year MFA candidate pursuing Design Research and Development at the Ohio State University.
Design for Wellbeing: Generative Visual Music for Anxiety Reduction

Emily Verba Fischer, University of Cincinnati, Ohio, USA, emily.verba@uc.edu

John Hebbeler, University of Cincinnati, Ohio, USA, john.hebbeler@uc.edu

Abstract

In societies where productivity is prioritized over presence, anxiety abounds. The extensive and alarming effects of anxiety on the mental and physiological wellbeing of bachelor students inspired a cross-disciplinary team to tackle this problem. Using combined expertise in visual design, music technology, psychology, art therapy and mindfulness — a digital tool entitled “Modes” was born. The Modes digital tool is an atmospheric, introspective, and aesthetically sophisticated engagement of three senses: ophthalmoception (sight), audioception (hearing), and tactioception (touch). Through immersive interaction, mesmerizing visual and sound landscapes are generated in order to reduce anxiety in bachelor students. The two measurable outcomes of Modes are 1) the reduction of self-reported anxiety in bachelor students, and 2) the reduction of bachelor student heart rates.

Interacting with the Modes digital tool is like playing in a sandbox of dynamic visuals and music. Users begin by selecting and entering one of three digital environments entitled Refocus, Chill, or Energize. Each environment (or mode) offers a unique set of visuals and music designed specifically for anxiety reduction. The design and functionality of Modes are rooted in tenets of mindfulness practice and Ayurveda — an ancient Indian healing system emphasizing inner balance as a method for maintaining health and wellness (Kiefer, 2016). The Refocus, Chill, and Energize modes aim to balance each of three governing principle of Ayurveda that regulate physiological activity. Ultimately, users may combat and control their anxiety in three targeted ways: by refocusing, chilling, or energizing.

Keywords: wellbeing, visualization, interaction, motion, sound, cross-disciplinary
Ayurveda — an ancient Indian healing system emphasizing inner balance as a method for maintaining health and wellness (Kiefer, 2016).

**Literature Review**

**Mindfulness Practice Ameliorating Stress**

A recent scientific study completed by individuals at the Bender Institute of Neuroimaging, Justus Liebig-University in Giessen, Germany, Massachusetts General Hospital, Harvard Medical School, and Brigham and Women’s Hospital (Harvard Medical School) concluded that the “cultivation of mindfulness, the nonjudgmental awareness of experiences in the present moment, produces beneficial effects on well-being and ameliorates psychiatric and stress-related symptoms” (Hölzel, Lazar, Gard, Schuman-Olivier, Vago, & Ulrich, 2011). This research (entitled “How Does Mindfulness Meditation Work? Proposing Mechanisms of Action From a Conceptual and Neural Perspective”) presents evidence that mindfulness practice is associated with neuroplastic changes in several areas of the brain. This research reinforces the hypothesis that a *multisensory* interpretation of mindfulness practice via the digital tool will produce similar effects in Modes users.

**Heart Rate Impacted by Mindfulness Practice**

Studies also show mindfulness impacts health and heart rate. The studies of Krygier (2013) conclude that the practice of mindfulness directly contributes to heart rate variability and a positive increase in health. A documented study from the article “Mindfulness Meditation, Well-being, and Heart Rate Variability” proved that “participants improved significantly on all positive psychometric measures of psychological health and well-being, including positive affect, satisfaction with life and mindfulness (Krygier, 2013, p.308).” The overall goal of this study explored the impact on mindfulness and the effects on participants’ health while researching cardiovascular data. “The Effect of Mindfulness on Heart Rate Control,” was “an experiment conducted to test the hypothesis that mindful attention to change regarding heart rate (HR) would result in greater control over HR (Delizonna, 2009, p.64).” This study provided “supportive data for mindfulness as a working strategy for emotion regulation, mindfulness as a conduit for improved health, and mindfulness requiring a switch in general cognition to making novel distinctions (Delizonna, 2009, p.65).”

**Ayurveda for Health and Wellness**

Medical studies consistently link psychological disorders such as anxiety and depression with physical wellbeing (Remington, & Brownson, 2011). The balance of mind and body is of fundamental importance in maintaining “complete health” in Ayurveda. Further, understanding the tenets of this ancient Indian healing system gives clues into the early development of many illnesses (Hankey 2005). Morningstar (2008) states, “Ayurveda provides a guide to lifestyle and ways of healthy living appropriately individualized for each person. Thus, “that which tends to go out of balance easily can be returned to homeostasis through meditation, breathing exercises, yoga, diet, sleep, music, and/or nature.”
Research Methods

The two measurable outcomes of Modes are 1) the reduction of self-reported anxiety in bachelor students, and 2) the reduction of bachelor student heart rates. The research study design for Modes address both of these outcomes. First, participants will complete a consent form and a demographic questionnaire. They will then complete the self-report State-Trait Anxiety Inventory (at Time 1); these are physical papers that will be collected. The State-Trait Anxiety Inventory includes items such as “I am tense; I am worried” (Spielberger, Gorsuch, Lushene, Vagg, & Jacobs, 1983). Each item is rated on a 4-point scale (Almost Always to Almost Never). In addition to the State-Trait Anxiety Inventory, participants’ baseline heart rates will be measured using HeartMath equipment (at Time 1); these will be digital data recorded within software. Once these two measurements are complete, the participants will interact with the Modes digital tool on distributed iPads for 5 minutes. Upon completion (at Time 2), participants will complete the State-Trait Anxiety Inventory again, and baseline heart rate will be measured again using HeartMath equipment. The two measurements are meant to support and compound each other’s results. For the data analysis, Statistical Product and Service Solutions (SPSS) will be used to enter and analyze data. T-tests will be conducted to compare whether Modes was effective in reducing the State Anxiety Inventory and heart rate variability measures. Paired sample T-tests should show decreased levels of anxiety from Time 1 to Time 2.

Discussion

Interacting with the Modes digital tool is like playing in a sandbox of dynamic visuals and music. Users begin by selecting and entering one of three digital environments entitled Refocus, Chill, or Energize. Each environment (or mode) offers a unique set of visuals and music designed specifically for anxiety reduction. The Refocus, Chill, and Energize modes aim to balance each of the three governing life principles of Ayurveda that regulate physiological activity. Ultimately, users may combat and control their anxiety in three targeted ways: by refocusing, chilling, or energizing.

The Three Life Principles (Doshas) of Ayurveda

According to Ayurveda, consciousness (listening to one’s body and making informed decisions) gives rise to human perception. There are five basic elements that comprise everything humans perceive through the senses: space, air, fire, water and earth. These five elements dynamically combine and organize themselves into three life principles, or three doshas. In Sanskrit, these terms are known as Vata (the air and movement principle), Pitta (the fire and metabolism principle), and Kapha (the earth and protection principle). All humans possess qualities of the three doshas, but everyone has an inherent tendency towards one. Some individuals are primarily lively and airy (Vata), others are primarily passionate and fiery (Pitta), and others are primarily grounded and earthy (Kapha). This primary dosha constitution is established at birth, but lifestyle choices can imbalance these doshas over time. If one’s primary dosha is out of balance, psychological and physiological anxiety is experienced. The following two sections describe how the visual design, interaction design, and sound design of Modes aid in rebalancing bachelor
The Visual and Interaction Design of Modes

The visual design within each of the three Modes environments is very specific in how it assists in balancing each of the three doshas (Vata, Pitta, and Kapha) to reduce anxiety. The visual design methodology of Modes may be considered in two parts: color and the circle. Color plays a strong role in guiding a user towards anxiety reduction. Three functional attributes of color are considered within each digital environment. These three elements include hue, “a property of color that represents the generic names of family groups within the visible spectrum (Puhalla, 2011, p. 62),” saturation, “brightness, or color intensity” (Albers, 1963, p.16), and value, a color’s lightness or darkness (Puhalla, 2011, p. 62). Since each dosha requires different properties for achieving balance, the hue, saturation and value are designed specifically for these properties. The Refocus environment within Modes is designed for Vata (Air) imbalance. When there is an overabundance of Vata within the body, the goal is to add elements of the Kapha (Earth) dosha to counter the imbalance. The color manifestations of Kapha are warm earth tones (hue), mid-to-high saturation, and dark, heavy values. The Chill environment within Modes is designed for Pitta (Fire) imbalance. When there is an overabundance Pitta within the body, the color counterbalance is characterized by cool colors like blues and greens (hue), medium saturation, and medium values. The Energize environment within Modes is designed for Kapha (Earth) imbalance. When there is an overabundance of Kapha within the body, the goal is to counter with elements of the Vata (Air) dosha. This includes hues that include reds and oranges, extremely bright, bold saturation, and mid-to-dark values. The dynamic color variable behaviors in each environment are the guide for keeping users engaged in the experience. The carefully considered elements of hue, saturation and value combine as the vehicle that drives bachelor student users through the Modes visual journey.

The second consideration of the Modes visual design methodology is the circle. The shapes within the Modes experience are decisively constrained to circles only. “Geometrically, a circle is the result of just one structural condition. It is the locus of all points that are equally distant from one center (Arnheim, 1966, p. 60).” This fact renders the circle the perfect vessel to assist with the reduction of anxiety — there is no beginning and no end in a circle; it is a neutral shape. “The circle is the first, perfect shape… The space speaks of potential — the tension between what is achieved and what could be achieved. From the circle, we derive ideals and focus, both the halo of saints and the cross-haired target in gun sights. (Gestalten, 2008, p. 11).” The circles within the Modes digital tool multiply and employ different behaviors based on user interaction, or gestures. Gestures include tap, long press, swipe, draw, and pinch. The combination of the variable design elements (color and the circle) activated by user interaction — outputs a plethora of new and exciting media content each time a user engages with the Modes digital tool.

The Sound Design of Modes

The sound design within each of the three Modes environments is very specific in how it assists in balancing each of the three doshas (Vata, Pitta, and Kapha) to reduce anxiety. The sound design methodology of the Modes digital tool consists of two parts: music composition
and interactive frequency. The music composition is the foundation that guides a user’s quest for achieving balance and reducing anxiety. Within the music composition of Modes, three sound elements are dominant within each digital environment. These three elements include: timbre, “the quality given to a sound by its overtones, distinctive of a particular singing voice or musical instrument (Webster, 1996),” melody, “a sweet or agreeable succession or arrangement of sounds (Webster, 1996),” and rhythm, “the pattern of regular or irregular pulses caused in music by the occurrence of strong and weak melodic and harmonic beats (Kariger, 1995).” Since each dosha requires different properties for achieving balance, the timbre, melody and rhythm are written specifically for these properties. The composition in each environment becomes the glue or the guiding track for keeping bachelor student users engaged in the experience. The carefully considered elements of timbre, melody and rhythm combine as the vehicle that drives users through the Modes sound journey.

The second element of the Modes sound design methodology is the interactive frequencies triggered by user gestures. This sound application is based on binaural beats. Physicist Heinrich Wilhelm Dove originally discovered binaural beats in 1839.

He discovered when signals of two different frequencies are presented separately (one to each ear) the brain detects the phase variation between the frequencies and tries to reconcile that difference. In doing so, as the two frequencies mesh in and out of phase, the brain creates its own third signal, called a binaural beat, which is equal to the difference between those two frequencies. This technique can be used to quickly and easily guide your mind into any state (IMMRAMA Institute, 2001).

The interactive tones within the Modes digital tool not only harmonize with the music melody, but mesh cohesively with the existing musical frequencies to produce a third signal. Different tone samples are layered into the overall music composition. Since each musical composition is written in a defined scale with a specific tempo, each tone (or interactive frequency) follows the same key and pacing of the composition. While interacting with Modes, users are able to hear distinct third tones within different areas of the stereo mix as the brain interprets the frequency. This interpretation creates an experience that propels users to more balanced states, therefore reducing anxiety.

The effectiveness of balancing the mind and body through sound is a result of masterfully combining music composition with interactive frequencies specific to each digital environment within Modes. Effectiveness is also determined by the overall sound and musical properties that have been specifically written and recorded to counter each of the dosha imbalances. Each sound environment elicits a different “feel” unique to the dosha’s characteristics — and, in combination with the visual and interaction design elements, allows bachelor student users to Refocus, Chill, or Energize.

**Conclusion**

Ayurveda teaches that understanding how the basic elements of nature are expressed in our individual constitution enables us to make better choices to maximize health and wellness. The visual and sound design of the three environments within the Modes digital tool answer the optical and aural demands needed to reduce anxiety in bachelor students. The Modes digital tool accomplishes this through attention to color theory (hue, saturation and value), the
repeated and decisive use of the circle, interaction design, music composition (including
timbre, melody and rhythm), and interactive frequencies. The attention to visual, interaction
and sound design harmony within the Modes digital tool ultimately correlates to the inner
harmony experienced within the user when anxiety is reduced.

Emily Veरba Fischer is an Ohio native who returned to the Midwest after receiving her master's degree from the Basel School of Design. Prior to her studies in Switzerland, she lived and practiced design for a variety of corporate and cultural clients in New York City, San Francisco, Seattle, and the French Alps. Through these international experiences, she developed a teaching approach that emphasizes the concept of global citizenry in addition to design acuity. She believes that maximizing understanding of other cultures through interpersonal connection and the shared language of design can create a more empathic world for all. Emily’s academic research concerns information visualization — the creation and study of visual representations of data for ease of understanding by the masses. In our age of information overload, she is interested in the potential to marry ultra clear communication with aesthetic sophistication.

Emily is currently an Assistant Professor at the Myron E. Ullman, Jr. School of Design in the University of Cincinnati's College of Design, Architecture, Art, and Planning (DAAP). She frequently travels abroad to share her research and pedagogical activities. Her work has been featured in exhibitions and publications nationally and internationally.

John Hebbeler is a musician exploring areas of digital media, fusing elements of sound, video and web production with computer technology. As an Assistant Professor in Electronic Media at the University of Cincinnati’s College-Conservatory of Music (CCM), he teaches a range of courses that include advanced studio production, digital audio production, integrated media production, and special topics courses. Professor Hebbeler has created interactive trans-media compositions that integrate iPhone and Wii remote technology into live audio and visual performances. His work includes the development of computer-based applications for iOS.
mobile devices that use programming and accelerometer technology to integrate aspects of composition, production, and performance. His original compositions have been distributed by Spotify, iTunes (US, Japan), Amazon, Rhapsody, eMusic, Zune, Tradebit and Last.fm. Over the past decade, Professor Hebbler has worked extensively in music technology for clients including The World Association of Symphonic Bands, The International Tuba and Euphonium Association, The United States Jazz Ambassadors, The BBC, The Cincinnati Opera, and more.
Research on the user behavior between China and USA elderly people in public space

Na Wei, School of Design, Jiangnan University, Wuxi, China, na_wei80@126.com
XiangYang Xin, School of Design, Jiangnan University, Wuxi, China, xxydesign@yahoo.com

Abstract
The user experience difference between China and USA elderly people in using public space was discussed in this paper based on the questionnaire process. 1960 elderly people were selected from the four cities in Shanghai (China), Wuxi (China), New York City (USA), Cincinnati (USA) to complete the questionnaire, and the result shows the similarities and differences between the elderly people in China and USA. That is: The using frequency of the public space for the former is much higher than the later; the main purpose of the former in public space is sports and fitness, and relaxation is the chief choice of the later; weather condition and easy communication are the key factors for former to participate in public space, while timing is that for the later; all the elderly people in the two countries are favorite on the sports and fitness, but the party chatting is the feature of the former and the sightseeing is the feature of the later; the facility requirement is the most important attributes for the former to the public space, and the interaction design is the unique demands of the later, while the former had no interests on that demands. In the end, the reason for all the similarities and differences were analyzed in this paper, and the culture, the economics, as well as the politics factors were discussed in detail.

Key words: User behavior; questionnaire; public space; USA; China; elderly people

During the process of Chinese urban modernization, the development and construction of public space has accompanied a process of westernization; this development trend constantly draws from and pursues western concepts of urban public space. In the current wave of ever-changing urban space construction in Chinese cities, Chinese designers and urban managers have given relatively little consideration to the significance and value of designing urban public spaces from the perspectives of their users. Currently, the main body of users of China’s urban public spaces is the elderly, whose public lives are closely related to traditional Chinese culture. Conducting a study of the characteristics of public space use and the preferences of users by comparing elderly Chinese and elderly Americans helps Chinese researchers and designers to identify the unique needs of elderly Chinese people with regard to public space.

When researching the inherent physical characteristics of public space, academics have also conducted a good deal of research focusing on the users of public space. This class of research can further help people to understand that urban public spaces, which are used to hold daily activities and in which events occur, are affected by the preferences of their users. In the United States and United Kingdom in the 19th century, urban public spaces began to be developed extensively; being
viewed as places that could help the working class to improve their health and quality of life, in contrast to their dirty and cramped living conditions. From Broomhall's Master's thesis, "Study of the Availability and Environmental Quality of Urban Open Space used for Physical Activity," one can see that there are many objective factors affecting public space. These factors include the quality and quantity of space, and the effects of the characteristics (e.g. socioeconomic status, age, gender, and ethnicity) and psychological factors (e.g. self-efficacy, perceived obstacles) of potential users on individual preferences. From this, one can learn that in the field of urban public space research, the study of the usage behaviors of public space users has become a popular topic. Since the beginning of this century, Chinese society has become an aging society (China's Fifth National Population Census, conducted in 2000, shows that the population of those aged 65 and older was 88.11 million, or 6.96% of China's total population; the Sixth National Population Census, held in 2008, revealed that the population of those aged 65 and older increased to 118,831,709, or 8.87% of China's total population). However, most research regarding Chinese urban public space remains focused on children, young people, and the middle class. The developmental characteristics of population aging in China share some characteristics with American population aging, but also differ in some places. This paper aims to compare elderly people and their use of urban public space in China and the United States, and to thereby determine the similarities and differences of the values, cultural conception, and behavioral norms of American and Chinese elderly people with regard to public spaces. In doing so, this paper provides researchers and designers with valid information regarding the modes of use of public spaces by elderly people in the United States and China.

1. Questionnaire Design:
This study's questionnaire primarily addresses the following four questions. (1) The scope of objectives for which elderly people will visit public spaces; (2) The factors affecting elderly people's ability to reach public spaces; (3) The types of activities in which elderly people participate in public spaces; (4) The qualities that elderly people require in public spaces. It is hoped that addressing these four questions will allow for the collection of characteristic factors describing elderly people's use of public space, and individual preferences for public space qualities resulting from personal characteristics.

2. Data Analysis
2.1 Sample
This study has chosen 196 respondents from Shanghai and Wuxi in China, and New York and Cincinnati in the United States; the sample was selected primarily by random sampling; specific characteristics of the sample are shown in Table 1.

<table>
<thead>
<tr>
<th>Characteristics</th>
<th>China %</th>

<tr>
<td>70-79</td>
<td>34</td>
<td>23</td>
</tr>
</tbody>
</table>
Table 1 reveals the following information. The ages of respondents range from 60-85. For Chinese respondents from Shanghai and Wuxi, 62% of respondents are aged 60-69, 34% are aged 70-79, and 4% of respondents are aged 80 and above. For American respondents from New York and Cincinnati, 69.2% of respondents are aged 60-69, 23% of respondents are aged 70-79, and 7.8% of respondents are aged 80 and above.

2.2 Question Analysis

2.2.1 Analysis of Frequency of Travel to Public Spaces

The characteristics of frequency of travel to public spaces based on questionnaire surveys are analyzed in Table 2.

</table>

The proportion of people traveling to use public spaces from the younger elderly age group for both countries was much higher than the middle and older elderly age groups. The participation rate in public space activities of China's middle age group was higher than that of America's. However, the participation rate in public space activities for America's older age group was higher than that of China's. With regard to the frequency of travel to public spaces, elderly people in both countries mostly travel to public spaces at least once a week. Furthermore, data for Chinese elderly people were higher than those of Americans by 20%.

2.2.2 Objective Analysis

In the questionnaire, this question used an open response format, allowing respondents to summarize their personal objectives for going to public spaces. On the basis of this questionnaire, the authors have distinguished between two main categories of objectives for travelling to public spaces; the first is leisure, and the second is physical exercise. Here, activities such as climbing,
jogging, walking, and cycling are classified as physical exercise, and activities such as dancing, singing, reading, and scenery viewing are considered leisure activities. On this basis, statistical results are shown in Table 4.

### Table 4: Public Space Objective Analysis

<table>
<thead>
<tr>
<th>Type</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>China</td>
</tr>
<tr>
<td>Leisure</td>
<td>46</td>
</tr>
<tr>
<td>Physical Exercise</td>
<td>54</td>
</tr>
</tbody>
</table>

The data in Table 4 shows that most elderly Chinese people emphasize physical exercise in public spaces, at a rate nearly 9% higher than leisure. This is closely related to the current Chinese attitudes to health, wherein an increased number of elderly people hope to use exercise in public spaces as a means of improving their health. At the same time, American elderly people are more focused on leisure, with the prevalence of this type of activity exceeding physical exercise by 16%. This shows that American elderly people are more concerned with mental relaxation, and the spirit of public spaces is the pursuit of this goal.

2.2.3 Public Space Activity and Behavior Analysis

In Table 5, we have analyzed specific questionnaire data regarding the activities and behaviors of elderly people in public spaces, and have listed the top five activities and behaviors for elderly people in both countries.

### Table 5: In which activities do you participate in public spaces

<table>
<thead>

<td>30</td>
</tr>
<tr>
<td>Cards and Chess</td>
<td>12.1</td>
<td>0</td>
</tr>
</tbody>
</table>

Data in Table 5 shows that there is a relatively large variation between the activities pursued by elderly people in China and the United States. In China, elderly people enjoy group activities, such as group exercises including dancing and tai chi; these activities account for 37.9% of the responses of Chinese elderly people. In the United States however, individual activities are preferred, such as solo walking and solo scenery viewing. Furthermore, in the US, there are more independent physical exercises, such as mountain climbing, jogging, and cycling; such activities account for 30% of responses from American elderly people.

2.2.4 Analysis of Factors Affecting Ability to Reach Public Spaces

This question was presented in a multiple-choice format; respondents were required to choose a single response indicating the most important factor affecting their ability to reach public spaces from those listed in Table 6.

### Table 6: Factors Affecting Your Ability to Reach Public Spaces
One can see from the data presented in Table 6 that with regard to Chinese people, climate is the most important factor affecting elderly people's ability to reach public spaces, at 31%. Furthermore, with regard to the United States, time was the most commonly selected factor, at 41.7%. Previously, a good deal of research has stated that distance is an important factor affecting people's ability to reach public spaces, but in this study, only 8% of elderly Chinese people selected distance, which indicates that distance is not a determining factor for most elderly Chinese people.

2.2.5 Analysis of Public Space Characteristics
This question used an open response format, and aims to discover the preferences of Chinese and American elderly people with regard to public space characteristics. According to questionnaire open format response content, the authors have summarized the responses in four characteristics, as shown in Table 7. These characteristics are: natural environment, cultural and functional infrastructure, interactivity, and safety.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>China</th>
<th>United States</th>
</tr>
</thead>
<tbody>
<tr>
<td>Natural Environment</td>
<td>29.4</td>
<td>40</td>
</tr>
<tr>
<td>Cultural and Functional</td>
<td>49</td>
<td>30</td>
</tr>
<tr>
<td>Infrastructure</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Interactivity</td>
<td>0</td>
<td>26</td>
</tr>
<tr>
<td>Safety</td>
<td>21.6</td>
<td>4</td>
</tr>
</tbody>
</table>

The data presented in Table 7 shows that the top two characteristic requirements for public spaces for elderly Chinese people are functional infrastructure and natural environment, at 49% and 29.4%, respectively. For elderly American people, the top two requirements are natural environment and cultural and functional infrastructure, at 40% and 30%, respectively. American and Chinese elderly people have the following requirements with regard to natural environment: beauty, scenery, and field of view; with regard to nature, they require a natural environment, open venues and open spaces, trees, shade and greenery, lakes, reservoirs, bodies of water, beaches, soil, birds and animals, sunlight, climate, and fresh air. These preferences were the same for both countries, but American elderly people's requirements for environmental characteristics exceeded Chinese preferences by 10%. At the same time, Chinese elderly people's preference for public space environmental infrastructure exceeds Americans' by 19%. Elderly Chinese people are especially attentive to satisfying basic user requirements for infrastructure, such as long benches, tables, and cleanliness of public toilets. On the other hand, elderly Americans are more attentive to
whether public spaces hold concerts, and whether they have cultural and functional infrastructure that supports the spirit of cultural exhibitions. At the same time, a relatively large number of elderly Americans require interactivity in public spaces (26%). They hope for the opportunity to interact with people of other age groups, and hope that interactive behaviors can be enhanced in the public space. However, elderly Chinese people did not express a demand for interactivity in public space experiences. An unexpected result of this data reveals that 17.6% more elderly Chinese people stated safety as a required characteristic of public spaces.

3. Results and Analysis

3.1 Variation in the Behavioral Requirements of Chinese and American Elderly People

Variation in the behavioral requirements of Chinese and American elderly people has led to differences in their activities and behavioral objectives with regard to public spaces. Elderly Chinese people's behavioral requirements in public spaces tend to emphasize individual health and leisure, making physical exercise the most important behavioral objective of Chinese elderly people in public spaces. Chinese elderly people who are currently above age 60 grew up in the initial period after the establishment of the People's Republic of China; from a young age, they have been taught and raised to develop a habit of participating in-group activities; these behavioral habits deeply affect their behavioral patterns in their old age. Accordingly, in public spaces, elderly Chinese people more frequently display group activity behaviors. However, elderly Americans' behavioral requirements emphasize individual preferences and their pursuit. More Americans choose to go to public spaces to participate in leisure activities. Compared to the collective behavior of elderly Chinese people, elderly Americans are more attentive to democracy and freedom, and emphasize nurturing individual interests and hobbies. As such, elderly Americans participate in significantly fewer group activity behaviors in public spaces than elderly Chinese people. In their everyday lives, elderly Americans mostly go to public spaces individually, or with friends or relatives.

3.2 Variation in the Personality Characteristics of Elderly People in China and the United States

There are distinct differences between the personality characteristics of Chinese and American elderly people. Most elderly Chinese people grew up in a relatively closed society, before China's reform and opening; as a result, their personalities are more introverted and cautious when compared to the American baby boomers. Elderly Chinese people's use of and preferences for public spaces also display this unique introversion and caution. For example, with regard to the characteristic requirements for public spaces, Chinese people's requirement for safety was much higher than Americans' requirement for safety. It is commonly stated that Chinese urban crime rates are much lower than those of American cities, and so Chinese elderly people should naturally be more relaxed towards safety in Chinese urban public spaces. However, the survey results show that because of the introversion and caution of elderly Chinese people, they are much more alert with regard to safety when compared to Americans. Elderly Chinese people's safety requirements
are not limited to personal safety, but also extend to property safety, especially as they are concerned about the safety of their own property. In another regard, the introverted and cautious elderly Chinese people's willingness to interact with strangers is clearly lower than that of elderly Americans. This can be explained by the fact that a low proportion of elderly Chinese people indicated that interactivity was a quality that they required of their public spaces. Compared to American baby boomers, who are extroverted and outgoing, elderly Chinese people have introverted personality characteristics, and although they are willing to interact with young people, they often do not know how to express themselves, and are more likely to interact and participate in activities with people with whom they are more familiar.

3.3 Variation in the Social and Cultural Backgrounds of Chinese and American Elderly People

Differences in the social and cultural backgrounds of Chinese and American elderly people also cause differences in the types of activities in which they participate in urban public spaces, and their characteristic preferences for these spaces. China is currently experiencing a period of rapid socioeconomic and technological improvements, which is its first stage of modernization. In order to satisfy people's demand for material consumption and economic security, society gives priority to economic development. However, the American society has entered a stage of stable socioeconomic and technological development, which is the second stage of modernization; in order to satisfy people's demand for happiness and self-realization, priority is given to the development of people's quality of life.  

As a result, variation exists between the preferences for public space characteristics for elderly people from both countries. Chinese elderly people focus on the physical infrastructure of public spaces, such as whether public spaces provide a place for physical exercise, and related supporting services. However, elderly American people tend to focus on the personal experiences and quality of life that they can derive from public spaces, for example, whether public spaces provide them with beautiful natural environments, cultural infrastructure and services, and interactive activities.

4. Conclusions

This study surveyed elderly people in China and the United States as a means of comparing and contrasting the behavioral modes of these people in public spaces, the activities in which they participate, and their individual preferences. Using qualitative and quantitative research methods, this paper explored the significance and cultural value of the behaviors of elderly people in public spaces. This study finds that the frequency of visits, behavioral participation, and individual preferences of elderly Chinese people in public spaces vary significantly from those of elderly Americans. For example, elderly Chinese people utilize public spaces more frequently, engage in more group exercise activities, and because of their greater introversion and caution when compared to elderly Americans, their requirements with regard to functional infrastructure and safety in public spaces are clearly higher than those of elderly Americans.

Funding
This Study was funded by Jiangsu Province Social Science Foundation for youths (13LSC011).

Co-creation supporting collaboration across cultural contexts: Recommendations for improving in flight packaging for ageing populations

Emily Wright, Swinburne University of Technology, School of Design, Melbourne, Australia emwright@swin.edu.au

Increasingly universities are adopting a collaborative approach to ensure research outcomes have industry-relevant impact. This collaboration has known challenges given the complexity of the process which requires successful negotiation across the needs of various stakeholders, disciplinary knowledges and cultural contexts. A co-creation approach in collaborative research can assist in navigating these challenges by empowering all stakeholders including industry, the academy and the community. This paper presents a case study of an industry engaged research project that employed this approach. Partnering with a northern European international airline and universities from Australia and Singapore, the project investigated opportunities for innovation around the ageing population’s user experience with in-flight packaging. Applying case study method, data collected included in-flight observations, expert interviews, co-creation workshops and prototyping. Challenges as well as opportunities are identified around how the co-creation approach supported the industry relevant outcomes of the project. The findings suggest that co-creation supports better outcomes for collaboration across the complexity of industry engaged cross-cultural research projects.

Key words: Industry-engaged research, co-creation, cross-cultural, ageing populations, in-flight user experience, packaging

Increasingly universities are adopting a collaborative approach to ensure research outcomes have industry-relevant impact. The Australian Government has revised how research is measured by adding a greater emphasis on research impact as well as quality. The National Innovation & Science Agenda initiative supports industry engaged research that benefits the Australian economy and society. The new measures are intended to promote innovation and support commercially viable outputs from publicly funded research. (Australian Research Council, 2016). Given the applied, real world context of industry engaged research, there are unique challenges inherent to the process when collaborating with industry and the academy. These challenges include navigating the complexity of the research parameters and in addition requires successful negotiation across the needs of various stakeholders, disciplinary knowledges and in the case of this project, different cultural contexts.
Literature Review

A co-creation approach in collaborative research can assist in navigating these challenges by empowering all stakeholders including industry, the academy and the community. The notion of co-creation can mean different things to different people and thus is not well defined. Nevertheless, it is accepted the term refers to the process of collective creativity (Sanders & Stappers, 2008). While successful co-creation can be challenging, its collective method supports negotiation across complexity and various stakeholder points of view (Coddington et al., 2016). More importantly for industry-engaged research, it supports the articulation of value amongst the various stakeholders (Degnegaard, 2014).

Research Methods

This poster presents a case study of an industry engaged research project that employed a co-creation approach. The project was undertaken by the Design Factory Melbourne based at Swinburne University of Technology in partnership with a northern European international airline. In addition, research was carried out in collaboration with the Live Well Collaborative Singapore and Nanyang Polytechnic, School of Design. The project investigated opportunities for innovation around the ageing population’s user experience with in-flight packaging.

The project challenge and context
While the airline is based in Northern Europe, a key growth area was identified with almost half of the airline’s overall passenger traffic going to Asia. Singapore is a major hub for these flight connections. The research challenge was to investigate the user experience of in-flight packaging touch points for the 50-plus age Asian consumer. During the in-flight experience a user interacts with a variety of packaging. From enjoying a drink and a meal to the purchase of gifts, packaging is a vital touchpoint in the delivery of an airline service. See Figure 1 for an example of one of the personas developed to represent the target market. The 50-plus consumer market is growing and has varying unmet needs around accessing and using in flight packaging.

Lee is a 50 year old business man, living and working in Osaka. Lee lives in a large inner-city apartment with his wife Sumi and their two children, Yuki (13) and Kato (17). Because of the long hours he works, Lee doesn’t get a lot of free time to relax so when he does he likes to spend it with his family.
An inclusive design approach ensures all users are afforded frustration-free packaging (Keates & Clarkson, 2004; Arthritis Australia, 2015). While most travel packaging may be designed for utilitarian purposes, traditionally packaging within Asia is valued for aesthetics as well as functionality. The role of culture for both Asia and the Nordic regions is important consideration in this design challenge. The sustainable impact of airline packaging is also a key consideration when considering the triple bottom line. “Airline passengers generated 5.2m tonnes of waste in 2016, most of which went to landfill or incineration, the International Air Transport Association (IATA) estimates. That’s the weight of about 2.6m cars. And it’s a figure set to double over the next 15 years” (Boyd, 2017, para 2). Wasteful packaging is not just a problem for the airline industry’s carbon footprint but also very expensive to manage.

The research

The team undertook research to clarify the context and use of packaging within the flying experience and created a series of concepts and recommendations for packaging improvements in the future. Applying case study method, data collected included in-flight observations, expert interviews, co-creation workshops, design ideation and prototyping.

First in-flight observation was undertaken by 12 Australian design students on their flight from Melbourne to Singapore. Observations were recorded by note taking and photographs when appropriate. Figure 2 demonstrates the POEMS framework used for data collection.

Figure 2: POEMS framework

![POEMS framework](image-url)
Second, expert interviews were undertaken with 2 staff members at the Live Well Collaborative around their knowledge of designing for ageing populations in Asia and in particular their work with air travel experience design. Third, co-creation workshops provided an opportunity to ideate around travel packaging for the 50-plus consumer group. Workshops took place at the Live Well Collaborative and at Nanyang Polytechnic School of Design, involving staff and students from the respective schools. An empathy exercise was conducted, whereby the team members had the opportunity to wear the ‘Silver Suit’, a suit which mimics the physical impairments that may occur in the 50+ age group. This was a useful test which highlighted the everyday mobility restrictions of this age group. Figures 3 refers to activities undertaken during the workshops including the “Silver Suit” simulation for testing out ideas.

Figure 3: Silver Suit simulation and co-creation workshop activities
Finally, prototypes were generated in the co-creation workshops and these were expanded and refined upon return to the Design Factory Melbourne. The data was then analysed and synthesized into a series of personas, user journey maps and opportunity identification insights (see Figure 4).

**Discussion**

**Findings and recommendations**

The use of personas and journey maps assisted the team’s investigation with problems identified including constrained space in-flight, lack of usability, packaging waste and absence of clear labelling. Recommendations for the airline’s in-flight meal packaging include being stackable and lightweight; renewable and compostable materials; ergonomic and accessible; clear labelling in multiple languages.

**The outcome: sustainable, accessible and legible**

The prototype concept takes inspiration from the Singaporean “tingkat”, a stackable meal compartment system that is more commonly used by the older generation in the region. Referencing a familiar meal system will resonate with the 50+ Asian target market, balancing an Asian as well as Nordic design aesthetic that marries well with the airline brand (See Figure 6).
The proposed design is sustainable, accessible and features clear, legible labelling. First, the design is sustainable utilizing a lightweight, stackable design made from a mix of renewable, compostable and recyclable materials lightening the airline’s carbon footprint. Second, the design is accessible for the 50+ consumer. It manages the space limitations of in-flight meal tray tables. The stackable system allows the consumer to easily access different parts of the meal and also provides space to store the excess packaging or food left behind. Hot and cold compartments house the various meal options allowing flight attendants to serve the meals in courses or all at once, stacked one upon the other as needed. Third, legible labelling ensures clear and comprehensive product information on the packaging, including the use of infographics and different languages, which will ensure the package and meal contents are easy to identify and use. A more accessible and sustainable in-flight meal packaging system solution will support the airline in expanding its Asian market while better servicing the needs of the growing 50+ consumer market.
Conclusion

In conclusion, challenges as well as opportunities emerged around how the co-creation approach supported the industry relevant outcomes of the project. Challenges included negotiating the uncertainty of working across cultural contexts with students collaborating from both Australia and Singapore. In addition, building a shared understanding of the project with the various stakeholders was at times difficult. Opportunities of the co-creation approach included bringing together the various disciplinary knowledges and various perspectives of the stakeholders from users to designers to industry experts in the area around the challenges of ageing populations and flight experience design. These findings suggest that co-creation supports better outcomes for collaboration across the complexity of cross-cultural research projects.

Finally, a big thank you to the staff, students and research participants who were so generous with their expertise and time.
Transportation Assistive Device for the Elderly Based on Service Design

**Hsien-Jung Wu**, Department of Creative Product Design, National Taichung University of Science and Technology, Taichung, Taiwan, psuhjw@nutc.edu.tw  **Yu-Ting Chou**, Department of Creative Product Design, National Taichung University of Science and Technology, Taichung, Taiwan, sally920678@gmail.com  **De-Fang Chu**, Department of Commercial Design, National Taichung University of Science and Technology, Taichung, Taiwan, selinachu1026@gmail.com  **Chia-Yu Chien**, Department of Commercial Design, National Taichung University of Science and Technology, Taichung, Taiwan, chien.chiayu@gmail.com

**Abstract**

Commercial products specially designed for the elderly have assumption of user disability and focus on assistive tools design. However, recent studies show aged people gradually stay healthy condition because of modern advanced medical technology and service. There so-called “platinum society” that describes a group of aged people live in a community where they have to take care of themselves under healthy condition. To respond to above situation, this study applies service design model to explore daily life requirement of the elderly and proposes a new transportation assistive device design located aside the bus station. From empathy map analysis, point of view definition, requirement-and-function deployment, to service model construction, real daily life activity and movement of the elderly are collected and analyzed. A participative design approach is applied to involve senior citizen participation that is helpful to retrieve their intangible needs. In this proposed design, it includes an information interface and an exercise assistive device for the elderly to use during the waiting period when they stay at the bus station. It provides required information for transportation purpose as well as simple exercise movement that make it form an area of social connection. Instead of boring waiting time wasted at the station, it enhances interaction between the elderly through uncomplicated stretch movement and conversation. A scaled prototype is implemented to simulate and test the scenario and interview is executed to collect feedback from the elderly. Ongoing progress show a feasible application can be achieved by integrating with current environment.

*Keywords: assistive device, transportation, the elderly, service design*
People live longer and healthier than ever before thanks to the continuous technology development. It’s more common that the ratio of senior citizens increasingly expanding in a community or country all over the world. This situation will become more obvious in some countries where the birth rate comparatively reduces in an astonishing way. Taiwan, for example, recently faces the above problem of population moving from aging to aged society. Product and environment design targeted at groups of the elderly therefore should be paid more attention since the senior citizen’s requirement are totally different from those of young people. Commercial products and systems especially designed for the elderly usually have assumption of user disability and focus on assistive requirement. In terms of user need, it has been switched from “health maintenance” to “living quality improvement” and accorded with the truth that aged people gradually stay healthy condition due to advanced medical technology and service. Specific consideration of product and system development and design for a group of healthy senior citizens live in a community is imperative to provide them with safe and high quality living environment. Issue of food, clothing, residence, transportation, education and entertainment are all related to wellness and well-being for the elderly. In addition to independent daily life in a house or apartment, an outer social network is another important factor for them to enhance the quality of life. A convenient and comfortable transportation approach for the elderly is required to extend their connection with the rest of the world. In Taiwan, taking a bus is widely adopted by the elderly as a transportation approach to reach further connection either physically or psychologically. This study intends to develop a transportation assistive device for this specific group users by using the service design approach. Starting from analyzing user requirement, the proposed design provides required information for transportation purpose as well as simple exercise movement that make it form an area of social connection. A scaled prototype is implemented to simulate and test the scenario. Detailed development process is described in the following sessions.

**Literature Review**

Many countries endeavor to find solutions for the falling birthrate and demographic aging. In consideration of the increasing number of senior citizens in our society, either healthy or disabled, it is imperative to recognize the real need of this group in relation to medical and non-medical care. Theoretically, the elderly use medical care more often than others (Berkelmans et al., 2010). It is understandable that the elderly can maintain wellness and well-being if their functional failure are minimized during hospitalization (Kim et al., 2017); a senior-friendly hospital environment is required, in other words. Also, housing environment is absolutely relevant to the functional capacity of the elderly. There will be negative health consequence for them if the housing environments cause weak performance of daily activities and reduced participation in social life (Granbom et al., 2016). Accessibility problems for the elderly living in ordinary housing are quite noticeable in areas such as entrance and kitchen.
Therefore, product and system development and design for the elderly have been largely paid attention to the above concern (Skrzek et al., 2015). Advanced technology like robots and mobile service are widely used to assist with the in-home care of the elderly and people with numerous types of disabilities. The introduction of pervasive and ubiquitous system become increasingly embedded in artifacts and environment to provide important health care and social service (Maglogiannis et al., 2014). However, since aged people gradually stay healthy condition because of advanced medical service, non-medical care and service become more pressing for them to improve their life quality. Consideration of transportation and entertainment for the elderly who have no problem with walking become important to enhance their life independence. Recent research works present many examples to respond to this emergent trend. Manzi et al. (2017) proposed a cloud robotic system to extend the capability for interaction and support the elderly during daily activities such as participation in social events, to enhance their independent living. The elderly even can keep pace with the current era by using a variety of technical equipment and smart devices through learning (Vacek and Rybenska, 2016). Using communication and visualization technologies, which include Augmented Reality (AR), Virtual Reality (VR) and QR codes, and the elderly can improve their social and personal well-being (Fernandez et al., 2017). Hung and Sunder (2016) investigated why senior citizens use Facebook and how they participate in specific activities on Facebook to meet their needs. Their result found four interesting motivations for using Facebook: social bonding, social bridging, curiosity and responding to family member requests. Moreover, a case study in Taiwan shows the elderly can use scientific knowledge to solve problems by designing toys (Chen et al., 2013). The above research works greatly indicate the trend and need of providing products and services, in addition to medical service, especially for the healthy elderly to improve their independent living with better quality.

Research Methods

Among the basic living requirements, transportation and entertainment are two of the most essential factors for the elderly to improve their social connection with outer world when they are in an independent living situation. This study aims to develop a product/service for the elderly based on their daily requirement using service design model. Several design methods are applied to identify design requirement before the ideation of this project – rapid ethnography, empathy map, point-of-view analysis and customer journey definition. The activity of taking a bus is selected as the transportation event since it has important role of social connection.

Ethnography is suitable for the project where the intent is to provide an in-depth description of everyday life. This study visited five subjects (ages 65-75) and participate in their natural
habitat and witness specific activities related to the event of “taking a bus”. These observation and records give us an insight into the problems and requirements of the transportation activity (taking a bus) for the elderly. Six incidents are recorded during the subject observation phase:

1. Most of them feel anxious under unfamiliar environment
2. Queue jumping behavior is more common than young people have
3. Instead of IT technology, the elderly usually ask about bus route orally
4. Literal description are normally ignored by the elderly
5. Offering seat to the elderly on the bus is common
6. Few passenger will actively talk to the elderly regarding problem solving

In terms of providing better transportation environment for the elderly, four user problems are identified based on the above observation: information readability is poor at the bus stop, they are filled with anxiety about unfamiliar environment, too many uncertainty regarding bus route and schedule, and improper ergonomics on the bus and around the bus stop. To narrow down and refine design problem, one of the subject is interviewed and requested to write down specific activities and emotion. Furthermore, an empathy map is generated to analyze the unsubstantial requirement (Table 1).

<table>
<thead>
<tr>
<th>Do</th>
<th>Say</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Ask someone or bus driver</td>
<td>1. Question about route and schedule</td>
</tr>
<tr>
<td>2. Walk around</td>
<td></td>
</tr>
<tr>
<td>3. Call someone by phone</td>
<td></td>
</tr>
<tr>
<td>Feel</td>
<td>Think</td>
</tr>
<tr>
<td>1. Anxious</td>
<td>1. Useless information</td>
</tr>
<tr>
<td>2. Boring</td>
<td>2. Get on bus quickly</td>
</tr>
<tr>
<td>3. Time-wasting</td>
<td></td>
</tr>
</tbody>
</table>

Several potential design directions are then created by POV (point-of-view) analysis as follows:

1. Providing distinct information
   - How might we reduce the ambiguity of transportation information?
   - How might we reduce the anxiety due to environment unfamiliarity?

2. Improving transportation efficiency
   - How might we reduce the chance of taking wrong bus route?
   - How might we reduce the time waste because of doubtful information?

3. Enhancing social connection
   - How might we create chance of social interaction?
**How might we increase pleasure emotion during transportation event?**

Scenario of taking a bus for the elderly is described as a persona and a customer journey based on the character retrieved from the subject we interviewed. A kiosk installed around the bus stop is initially determined as the target device. Nine touch points are especially defined as service functions in terms of relation between activity and device (Table 2):

<table>
<thead>
<tr>
<th>Activity</th>
<th>Responding device area</th>
</tr>
</thead>
<tbody>
<tr>
<td>Screen displays route information</td>
<td>Kiosk interface</td>
</tr>
<tr>
<td>Baggage storage</td>
<td>Kiosk storage at back side</td>
</tr>
<tr>
<td>Touch screen</td>
<td>Kiosk interface</td>
</tr>
<tr>
<td>Select destination by different items</td>
<td>Kiosk interface</td>
</tr>
<tr>
<td>Provide commercial information</td>
<td>Kiosk interface</td>
</tr>
<tr>
<td>Choose bus route</td>
<td>Kiosk interface</td>
</tr>
<tr>
<td>Display accurate selection</td>
<td>Kiosk interface</td>
</tr>
<tr>
<td>Stretch movement</td>
<td>Kiosk space at back side</td>
</tr>
<tr>
<td>Display bus coming information</td>
<td>Kiosk interface</td>
</tr>
</tbody>
</table>

**Discussion**

Ideation process is then triggered to develop a kiosk installed around the bus stop where scenarios are simulated to satisfy the result of POV analysis. Two requirements of taking a bus for the elderly are emphasized: transportation purpose and social connection. Initial and modified sketches are shown in Table 3.

<table>
<thead>
<tr>
<th>Table 3: Sketches at different phases</th>
</tr>
</thead>
</table>

The final version design of this kiosk is installed beside the bus stop. It provides passengers with required information about bus route and schedule. Handle bars are embedded at both sides of the kiosk whose back side has a space for the elderly to exercise simply and chat with
other passengers. The concept is to decrease the anxiety caused by the uncertainty and unfamiliarity through operating kiosk interface in an effortless manner and killing time by simple exercise at the back of the kiosk. Table 4, 5 and 6 show the interface example, the process of mock-up and final prototyping after the design review respectively.

Table 4: Interface examples

<table>
<thead>
<tr>
<th>AM 8:00</th>
<th>35 6 29</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017/07/23</td>
<td>56 9 51</td>
</tr>
</tbody>
</table>

Table 5: Mock-ups

Mock-ups are used as a base of design review through the inclusive approach. Subjects are explained about the design concept and guided with defined scenario of using the kiosk. To respond to the questions and suggestions received from the elderly subjects, design modification is processed and focused on the following issues:

1. Stretch area is more suitable at the back side to reduce embarrassment.
2. Temporary baggage storage is necessary for the elderly.
3. Add the item selection based on “direction”.
Conclusion

A computer simulation indicating the installation of the proposed kiosk design, a transportation assistive device for the elderly, is shown in Figure 1. It intends to provide a helpful device installed beside the bus stop for the counter stereotype of the elderly who actively go out to expand their social connection. A comfortable and familiar atmosphere accompanied with clear information interface are the major concern of this kiosk design. The body stretch area at the back side of the kiosk offers the elderly passenger a place for simply exercising when they are waiting for the bus to arrive. It attracts the elderly to chat with others without embarrassment by stretching their body naturally. At the front side of the kiosk, a concise interface is proposed to reduce the information ambiguity. The study applies the service design models to retrieve user-centered design requirement. An inclusive design approach including rapid ethnography and design review shows that the study proposes another perspective to deal with issue of enhancing the life qualify for the elderly.

Psychological Effects of an Art Program with Feedback Systems Reflecting Achievement Levels in Rehabilitation Exercises

- Development of a VR Device Encouraging Squatting Movements -

Kiyomi YOSHIOKA, Meisei University, Tokyo, Japan
kiyomi.yoshioka@design.meisei-u.ac.jp

Abstract

We developed an art program that connects rehabilitation exercises with the creation of art. The quality and level of rehabilitation exercise achieved in the outcome of the resulting artwork is reflected as feedback to encourage patients to perform their rehabilitation exercises. The art program is called “Let’s stand up and draw art in the sky!” and utilizes a virtual reality (VR) head-mounted display device to create a landscape image in the device’s display area, through the movements of sitting down and standing up. To replicate the rehabilitation movement of standing then sitting on a chair, a squat exercise experiment was conducted with and without the art program, using university student subjects, and the results were compared between the two trials. When the subjects used the program they reported a significant increase in the "Level of Vitality" and the "Level of Pleasure", compared to when they performed the exercises without the art program.

Keywords: Virtual Reality, Rehabilitation, Art Program, Feed Back, Psychological Effect, Active Art

Sustaining patient motivation to perform simple and repetitive exercises is a problem in rehabilitation aimed at the recovery of physical function [Note 1]. In recent years, game-based rehabilitation devices have become available, but they merely give movement instructions or display the number of movements performed [Note 2, 3]. In this research, to encourage patients to perform their rehabilitation exercises, we developed a collection of art programs, generally referred to as the “Active art rehabilitation program” (patent pending), that connects rehabilitation exercises with the creation of art and reflects the quality and level of rehabilitation exercise achieved in the outcome of the resulting artwork as feedback.
**Literature Review**

Previous studies of "Active Art" programs that make art works by touching a computer touch panel and squeezing a rubber air pump showed effects of improved mood and rehabilitation assistance [Note 4-6]. These previous programs are expected to help maintain patients’ motivation towards performing simple and repetitive rehabilitation exercises through the psychological effects of art, which occur when patients interact with art and the human senses are stimulated as a result of the interaction, and through the creative work of art making. In this research, an art program called “Let’s stand up and draw art in the sky!,” which included sitting-down and standing-up movements, was developed to create a rehabilitation device. The purpose of this research was to maintain patients’ enthusiasm and motivation towards performing simple and repetitive rehabilitation exercises and to promote the recovery of the patients’ physical functions.

**Importance of Sitting Down and Standing Up Movements**

Sitting down and standing up are extremely important locomotive movements related to standing and walking in everyday life. In rehabilitation exercises, these training movements are used to strengthen a patient’s lower limb muscles and are used in balance training. They are used in various rehabilitation programs intended to improve functional impairment caused, for example, by post-stroke motor paralysis. The program can also be used in squat exercises to prevent the need for care in the elderly [Note 7].

**The “Let's stand up and draw art in the sky!” program**

A virtual reality head-mounted display device (Oculus Rift) was used to execute the “Let’s stand up and draw art in the sky!” program and to create a landscape image in the device’s display area through the movements of sitting down in a chair and standing up.

**Program Design**

(1) Evaluation of Achievement Levels and Feedback
The maximum amount of exercise (target number of sitting-down and standing-up movements) to be performed by the patient was chosen as the evaluation criterion. The amount of exercise (number of sitting-down and standing-up movements) performed by the
patient during the program was evaluated by using the evaluation criterion, and the level of achievement was reflected in the outcome of the resulting artwork as feedback. In this program, the patient was required to finish a piece of artwork after 30 or 50 standing-up movements. Achievement was evaluated in three levels in the program of 30 standing-up movements and in five levels in the program of 50 standing-up movements.

(2) Projected Images
The wearer of the virtual reality head-mounted display device was shown underwater scenes when sitting down and scenes from above the water when standing up. In the case of the above-water scenes, puzzle image pieces of scenes—for example, of World Heritage Sites—were added to the device’s display area in an orderly manner or the content (number of pixels and colors) of each puzzle piece was changed when the wearer of the device stood up (Figures 1 & 2). The program also involved a creative element: the scenic image created in relation to the level of rehabilitation exercise achieved by the patient could be printed out on a postcard sized artwork and taken home as a reward of the rehabilitation exercises performed. At the beginning of the program, the patient was able to choose, from among five types, the theme of the scenic image they wished to create.

(3) Design Factors Related to Motivation
Because the image appearing on the display area changed with the patient’s sitting-down and standing-up movements, the patient was able to visually acknowledge their movements. After each 10th standing-up movement, the patient heard a cheering voice telling them to “Keep up the good work!” The level of rehabilitation exercise achieved was reflected in the outcome of the resulting artwork as feedback.

Display when sitting down          Display when standing up

Addition of part images with coarse mosaics whenever subject stands up

Movements 11 to 20, of a 30 Movement Program:
Change to detailed images of fine mosaics whenever subject stands up

Movements 21 to 30, of a 30 Movement Program:
Change to part of the images seen clearly without mosaics whenever subject stands up

Fig. 2 Images of Feedback Reflecting Achievement Levels in Rehabilitation Exercises

**Psychological Evaluation of the “Let's stand up and draw art in the sky!” Program**

**Methods**

Participants were twelve healthy university students (Ages: 18 to 28 years; male, 3, female, 9.) A set of 30 squats with the art program and a set of 30 squats without the art program were
performed in random order with a few days break between set. A psychological evaluation using the two-dimensional mood scale – short term (TDMS-ST) was performed before and after each set of squat exercises [Note 8].

Results

Scores for “Level of Vitality,” “Level of Stability,” “Level of Pleasure,” and “Level of Arousal” with and without the art program, and before and after the squat exercises were tested by using a two-factor two-level analysis of variance. For “Level of Vitality”, a significant difference was found between with and without the art program (F(1, 11)=5.77, \( p<0.04 \)) and before and after the squat exercises (F(1, 11)=12.92, \( p<0.004 \); Figure 3). For “Level of Pleasure”, a significant difference was found between with and without the art program (F(1, 11)=4.97, \( p<0.05 \); Figure 5). For “Level of Arousal”, a significant difference was found between before and after the squat exercises (F(1, 11)=9.59, \( p<0.01 \); Figure 6).

The results showed an increase in the scores for “Level of Vitality” and “Level of Arousal” after the squat exercises. In addition, when the squat exercises were performed with the art program, the scores for “Level of Vitality” and “Level of Pleasure” were higher than the scores for the squat exercises performed without the art program.

“Level of Pleasure” showed an interaction effect (F(1, 11)=5.82, \( p<0.03 \)), and the simple main effect test found a significant difference (F(1, 11)=10.58, \( p<0.004 \)) between the evaluation done after the squat exercises with the art program and the one done after the squat exercises without the art program.

Analysis of the participants’ mood after squat exercises performed with and without the art program revealed a higher score for “Level of Pleasure” when they exercised with the art program.

![Scores](image)

Fig. 3 Comparison of scores for “Level of Vitality”
Fig. 4 Comparison of scores for “Level of Stability”

Fig. 5 Comparison of scores for “Level of Pleasure”

Fig. 6 Comparison of scores for “Level of Arousal”
Discussion

We conducted a psychological evaluation of the performance of squat exercises with and without using the “Let’s stand up and draw art in the sky!” art program. We found that “Level of Vitality” and “Level of Pleasure” were increased by using the art program, compared with not using it. We confirmed that simple and repetitive squat exercises can be performed with excitement and liveliness in a positive and comfortable mood by using the program. Moreover, the “Level of Pleasure” was increased significantly and participants gained a comfortable and positive feeling by performing squat exercises with the program.

Conclusion

We developed an art program called “Let’s stand up and draw art in the sky!” which gives feedback on the levels of rehabilitation exercise achieved by patients. When the squat exercises were performed with the art program, the scores for “Level of Vitality” and “Level of Pleasure” were higher than the scores for the squat exercises performed without the art program. The participants’ “Level of Pleasure” increased significantly when the program was used with the performance of squat exercises. Presently, the program is being implemented and evaluated in a recovery-phase rehabilitation hospital. The program is expected to help patients to maintain their motivation and to become actively involved in performing simple and repetitive rehabilitation exercises.

Conceptual Fashion and Media Research as site-specific Narratives

Andrea Zapp, Manchester School of Arts, Manchester Metropolitan University, United Kingdom, a.zapp@mmu.ac.uk

Abstract

This paper introduces academic research into conceptual apparel and fashion narratives that are inspired by diverse art and media aesthetics for unique collection stories. Distinct photography forms the design continuum with photo-real imagery carefully mapped onto patterns, creating fabric textures and garment shapes. They concentrate in their content on investigating place and space as a shared environment. The actual design practice is therefore embedded in a reflective discourse that is driven by exploring textiles as a social, factual or cultural platform for meaning and narrative. Fabric is treated as a screen and canvas for a collage of visual information, cultural environment, collective memory and association. In contextualizing this multi-disciplinary approach, wider theoretical implications and readings of narrative imagery in textile, fashion design and art are cross-referenced. A focus is on particular limited editions as a research model and case study within this practice. Bespoke ranges have been commissioned by partners in creative industries that explore site-specific histories and new insights for design outputs. They have been exhibited at international fashion weeks as well as in museum and gallery contexts. As a second outcome they have also played an important role by being commercialized in an academic spinout company and intersecting research strategy with academic enterprise. This is referenced in this context as an underlying support structure for dissemination of above experimentation.

Keywords: media fashion; design thinking; design semantics; collaboration; fashion and function

To fully understand the motivation of this design methodology that uses documentary site-specific photography for collection stories, it is necessary to look at the conceptual origins. They are rooted in research into digital media aesthetics and networking and subsequent installation art work that approached textile as a contextual medium from a more media-philosophical perspective. Vital research questions were dealing with the representation of the human body in the era of global networking, investigating an increasing and all-pervading symbiosis of virtual and real existences and platforms. As a key example, the installation Third Skin (2011) explored these allegories as a visual narrative for a dress collection. It was developed for the International Siggraph Exhibition for Digital Arts and Technology: Tracing Home, which took place in Vancouver. Playing with the idea of the virtual home, or in other words, the Internet as a parallel space of existence, the garments displayed imagery of virtual spatial environments such as Google Earth as another space we might reside in. By mapping those environments back onto the body through clothing, they aimed at merging the real body with the virtual one in an analogue-digital discourse. This metaphorical thought was
influenced by Marshall McLuhan's (1964) early understanding of media and technology as a direct augmentation that extends our human capacities, with clothing being an extension to our skin, in the way that media have become an extension, even prosthesis, to our bodies in general.

Building on this initial metaphor of virtual place and space, a signature language and contemporary fashion design model has been developed since that now uses photo-real imagery as a conceptual layer. Focusing on the designer’s own photography as an observation of architectural formations, landscapes or urban environments as contemporary narratives, it equally applies the shared place and space as an underlying design motif. This thought process is further influenced by aesthetics of locative media such as mapping techniques or Global Positioning Systems (GPS). To underline this spatial-analogical design philosophy, exhibitions of dress collections have been accompanied by a customised Google Map screen interface. It enabled visitors to travel virtually to the places and surroundings where the pictures featured on the garments were taken in.

**Research Methods**

**General Design Methodology**

Image research and garment pattern design are intertwined from the very beginning. Photos are taken with an understanding of needed structures, forms and detailing for a particular garment style and collection story in mind. They act as visual tableaus and mood boards, driven by factual as well as intuitive criteria, from which details are extracted and applied to a pattern panel. To comply with the visual-documentary design motivation, the photography remains
mostly unaltered apart from minor quality corrections. Diversification is achieved through extensive imagery footage rather than digital manipulation. Usually only one image is spread across a garment to compose a narrative of a particular place or subject in one piece. In parallel, garment shapes are designed, that are minimalist, linear and clear to allow for the photography to breathe and take center stage. Matching block colours are added to frame and emphasize the visuals.

The pattern is digitized and the imagery carefully mapped onto the pattern panels to further reinforce silhouette and form. The pattern parts are then arranged in lay plan files for placement print and fabric cut. Depending on the fabric properties, they are printed via digital inkjet (e.g. silk) or sublimation print (manmade fibers) to guarantee maximum quality in image resolution and print longevity.

Figure 2: Image-to-dress process. Design *Old Post Office in Liverpool* from *Captured around the World* collection.
The photo-real and non-distorted design focus builds direct references to the spatial backdrops and locations the pictures were taken in. However, the placement strategy and fabric print effects can also serve as a technique to blur those boundaries. In the collection *Bay of Naples* for instance, documentary imagery from the ruins of Pompeii was used deliberately to achieve results of image abstraction as another fabric pattern style and allowing for stronger fabric pattern effects. Photographic research on site was undertaken with the intend to give the delicate silk a fresco and painting-like quality, even tromp l’oeil in places, and in turn portraying the ephemeral and evanescent aura of this site.

![Figure 2: Design Lemonia from Bay of Naples collection.](image)

**Research into Academic Enterprise**

The broader, outwards facing and internationally recognized research background and academic trajectory has helped as a rationale to commercialize this design methodology in an academic enterprise model and to gain support from Manchester Metropolitan University. In 2014 a spinout company with university shareholding was launched - *AZandreaazapp/Media Textiles Limited*. In a proof-of-concept stage business plan, brand profile and marketing strategies were established, with samples being developed in-house but building on an external UK based manufacture chain for print and garment make-up. Being set up as an interdisciplinary platform and working cross-faculty, it enabled research assistances for graduates in design, patternmaking and fashion marketing. Collection outputs have since been showcased at the Saatchi Gallery during London Fashion Week, at Singapore and Paris Fashion Week, and at trade missions in Tokyo, followed by retail in Singapore, Japan and the UK at present. The profile, unique selling point and niche of this brand are distinctly hybrid in
its creative manifest. It bridges the gap between academic research, conceptual thinking and commercial output, balancing exposure in the creative exhibition sector with commercial ventures in the fashion industry.

“As a self employed fashion designer working within my own business structure and crafting my own vision throughout, it is important to note that my work has always been grounded in a strong and substantive research base. I have always believed in the pursuit of innovative methods of fabric development for structuring a personal design identity from within what is a very congested identity” (Dieffenbacher, 2013, p.7).

This conceptual diversity, the method of creating cultural analogies through photo-real fabric design – and last but not least - also the exposure on the international fashion market has attracted design commissions from creative and public industries over time. Since 2014 a range of limited garment editions have been developed with external partners; in a resourceful dialogue that investigates given histories and heritage to formulate a creative response in conceptual fashion. The design results were also made available for sale, either through the venue directly or through the AZ. company channels. They form another important strand of research output that is interlinked with commercial opportunity. External briefs did not only set new design inspirations but the commissioning infrastructure enabled to fund new production and sampling development.

Research through Location Method: Design in a museum context

Case study 1: Limited dress range for Manchester Art Gallery

Manchester Art Gallery and The Gallery of Costume are home to a world-class art collection of artefacts in fine arts, craft, design and costume and the collections include over 25,000 objects, developed over the course of 200 years. In this brief for a limited edition of three dresses, items from the craft and design collection were photographed to form a new pattern narrative. They were chosen for their visual distinctiveness and incorporated into a garment design that in turn aimed to interpret the particular aesthetics of the object through colours and forms.

The collection was also multiplied in external manufacture and offered for sale in the gallery shop.
Figure 3: Figure of a Girl, 1955-65, unknown. Made in Chodziez, Poland. Figures of a Donkey and a Dog, 1959. Designed by Lubomir Tomaszewski. Made in Ćmielów, Poland. Porcelain.

Figure 4: Dress Design Figurine, Dog & Donkey, limited edition.

Figure 5: Exhibition set-up.

The dresses were exhibited in the gallery space next to the objects that inspired them and with detailed information provided about their origin. Hence following an established model in museum collection work in that “these projects often result in temporary displays of contemporary work displayed alongside historic collections. Not only do they bring to
light contemporary responses to treasures that may have been overlooked by curators, but they also return to the museum’s permanent collection a greater sense of dynamism and relevance to contemporary life” (Hemmings, 2006, p. 16).

Case study 2: Paradise Mill Silk Museum, Macclesfield, Cheshire

In a similar model of devising a limited garment and related public exhibition, this project focused on the actual museum environment for the fabric visuals. Paradise Mill is a manufacture heritage centre in a Grade II listed original mill building and takes the visitor back in time to Macclesfield of the early 20th century. The loom floor contains 26 restored Jacquard silk handlooms, along with designers’ and managers’ offices.

The exhibition showcased three bespoke dress patterns, purchased for the collection, and large-scale design prints of additional 10 garments of the same narrative. It further included a bespoke accessories range of five scarves and ties. They have since been retailed in the museum and the dress collection has been exhibited at international fashion weeks under the title *Paradise Mill*.

![Figure 6: Paradise Mill Macclesfield, weaving shed.](image-url)

The fabric patterns re-imagine the museum’s archive for the 21st century. Printed on silk and hence in line with the heritage, the photographic compositions and visual detailing document the preserved working methods and machinery focusing on manufacture techniques such as spinning and weaving. Other garments are illustrating the fabric archives and swatches on site, by reproducing their textures and historic patterns through photographing and reprinting them. In bringing back to life this rich but now inoperative working culture and history, the garments then hint furthermore at today’s omnipresent offshore production channels for apparel that have led to the subsequent death of a formerly thriving local industry.
Work-in-Progress: Design with scientific data

Case study 3: British Antarctic Survey (BAS)

In this on-going collaboration with the British Antarctic Survey in Cambridge, the aforementioned location tracking and mapping interfaces are back in focus as an essential research question. BAS is an institute of the British Natural Environment Research Council (NERC) that delivers and enables world-leading interdisciplinary research in the Polar Regions. The project originated in the Data as Art initiative: Artists from various backgrounds were invited to collaborate with science partners on visualizing data in its widest definition; to create stunning and thought-provoking responses that are using real Antarctic data-sets to transmit science stories to a wider public audience.

In this context a garment design has been developed in a windbreaker and outdoor style, to align it with the climate specifics of this region. It also draws on inspiration from Inuit folklore costumes and early Antarctic explorer uniforms to complete this localised narrative. This time science photography footage from the image database at BAS was used as a visual resource, and a particular emphasis was given to the research field of seabirds. Imagery of penguins was applied to the pattern panels and the signature block colours in this case rounded out the utilitarian look.
The first impression of this design is a more picturesque one and almost endearing, due to the quirky appearance of the Macaroni penguin flock. This effect is enhanced through splitting and abstracting the image on the fabric pattern to achieve a more ornamental and de-constructed texture. But the actual image content references a research data pool that gathers evidence of the birds’ habitats and whereabouts by continuously monitoring and tracking the colonies throughout the year in Antarctica. Decorative design and fashion thinking then meet with scientific documentation and environmental findings in a new and unusual setting. To mark this multi-disciplinary discourse, a current proposal for upcoming exhibitions intends to show this garment within an installation context that displays live tracking data maps of the birds in real-time.
3. Literature review and discussion

Consequently, this multi-layered design practice is influenced by a semantic and semiotic strategy in which textiles, as defined by Sonja Andrew (2008), “are being theorized and evaluated using interdisciplinary theoretical approaches, drawing on methodologies from other disciplines to inform their analysis of textile content, practice and contextualization” (p. 45).

With the site-specific collaborations leading to new outcomes of conceptual apparel in the process, they can be analysed as a particular model of communication in which meaning is constructed and transmitted through the medium of fashion. They offer an additional interpretation to Malcolm Barnard’s (2014) theory of fashion being fundamentally “an interaction between cultural values and the items of clothing” (p. 89).

They visualise in their semiotic underpinning that “communication through or by means of fashion is a social and cultural interaction that constitutes us as members of those societies and cultures. (…). We use the things we wear to represent, or stand for what we think of us,
or as ourselves” (Barnard, 2014, p. 79). A fact that was proved most recently when former director of Manchester Art Gallery, Maria Balshaw, took up her new position at the helm of the Tate Museums in the UK. On her first day, which included many press opportunities, she chose the Figurine dress from the above range as her outfit. This was only shortly after an atrocious terrorist attack at the Manchester Arena concert venue. Much more than just making just an artistic fashion statement, it gave her the chance to send a meaningful, personal and very public signal to express solidarity with her former hometown and working environment.

Figure 10: Tate Director Maria Balshaw and team. *The Guardian*, online version, July 2017.

Overall, the designs comply with the following semantic criteria, based on Andrew (2008), identifying a textile as a narrative or communicative carrier, if it:

- Contains imagery that creates a visual narrative.
- Contains symbols, images or decorative motifs that have a specific meaning (even if this meaning requires specific knowledge or cultural experience to understand.)
- Contains colors, textures or patterns, which evoke a mood or feeling in the viewer.
- Communicates meaning through its contextualization - i.e. what it is made into and how or where it is shown (p. 33).

The contextualisation of photography on fabric and its successive connotations, together with (media-) artistic references and exhibition installation environments, are categorizing these collections as art objects on the one hand. On the other, by being an item of clothing with an inherent practical value, they communicate such visual information or heritage back into a popular, external and urban context. The artefacts as ready-to-wear garments are now also a tangible reality, in an almost inverted process of the ready-made in art, and they are placed inside and outside their elevated and auratic art status all at once. This is underlined by the fact that the collections were multiplied in an industry setting and offered for sale in the gallery venues and so fulfilling additional purposes. Fashion becomes art and art becomes
fashion as a reciprocal method and reading in this case. As Sanda Miller (2007) explains, clothes keep us warm, adorn us, but we can “equally regard them as beautiful objects of aesthetic contemplation by disregarding the ‘concept’ under which they fall and therefore ignoring their functional dimension. They could be (as indeed they are) objects of admiration in a museum” (p. 39).

Ulrich Lehmann (2010) has compared historic and current models of consumption in fashion and art and identifies shared values in both “since the institution of fashion, as clothing that adheres to particular modes of production, representation, and consumption, was connected to the emergence of similar structures in the creation and dissemination of works of art” (p. 30). As the above garments are cross-referencing cultural languages with functional purposes, we can agree that “the dialectic (not binary pairing) of ephemerality and permanence shape the respective reception of modern art and modern fashion” (Lehmann, p. 34).

4. Conclusion

Models of appropriation in design and through collaborations have been highlighted that can form a base for similar future and interdisciplinary exchange. Design ideas that interpret fashion and apparel as a visual medium can be applied to various contexts and research sites. These production and research initiatives can equally enrich the creative vocabulary of the designer, as well as enhance the environment of the participating partner. Fashion is not seasonal but referential. Garments are investigated as wearable artefacts that can carry knowledge and message and transfer it to a wider audience on different and diverse levels. At the same time they can provide innovative strategies of research implementation into external industries together with new research income streams.

Author Biography

Andrea Zapp

Born in Germany and currently Senior Research Fellow in Creative Technologies and Fashion at Manchester Metropolitan University. Internationally exhibiting media artist since the Mid Nineties and fashion designer with a strong artistic manifest. Multiple interactive networked installation work and lectures at international media festivals and conferences, such as Ars Electronica and Siggraph, and in museums and galleries across Europe, the USA, South America, Australia and Asia. Leadership in curation and production of international media arts and design exhibitions. Recent focus on narrative imagery for textile and fashion, further investigating the potential of future smart materials for new visual design concepts. Books published: Networked Narrative Environments as imaginary spaces of being. (2004). Liverpool/Manchester: FACT/ MMU; and New Screen Media: Cinema/Art/Narrative. (2002). London: British Film Institute.
